The West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers is a little broader in its scope than its name suggests, but it should be made national, with a section meeting at various points in West Virginia or in Huntington. Such services as it is already performing would justify the association in becoming the core of a national organization, for its meetings are well attended, its members are hard-working and enthusiastic and the character of its articles and discussions are of a high order. The society with advantage might invite prominent mine electrical engineers to address it, thus benefiting its membership while at the same time spreading a knowledge of the meritorious work it is doing, which is as yet none too generally recognized.

Many general managers and superintendents do not know a good electrical engineer when they have one at their plants. They regard him as a man too often who is making altogether too many demands on the rest of the personnel. He must furnish the electricity for others to use as wastefully as they please, yet he is held responsible for the electrical cost per ton of coal.

To such a man, hedged in by advocates of old traditions, an electrical association national in scope furnishes an opportunity not only to learn new ideas and methods and to see new machinery but to get the honors to which his talents and efforts have entitled him. It is strange that up to the present only West Virginia, Virginia and Kentucky have risen to the point of expression. In other places the electrical engineers are joining omnibus societies, making their addresses before mixed audiences or combining humbly with iron-and-steel men or triennially, quadrennially or whenever occasion serves getting into session as an appanage of the American Institute of Electrical Engineers. Such associations too general in their scope can never afford the technical pabulum and the helpful inspiration which every electrical engineer should enjoy.

IF CONGRESS, in its wisdom, decides to limit the amount of coal produced by limiting the number of mines, how is it going to prevent tremendous expansion of haulage and hoisting at each mine that inevitably will increase the country's volume of coal at the slightest market provocation? This problem of stopping coal-mine expansion is a nice, simple little one. Settling it by act of Congress is comparable to the famous resistance which King Canute set up against the tide of the sea.

Excuses Not Reasons

DRAMATIC and interesting are the references to Herrin in the Coal Commission report to Congress on civil liberties in the coal industry. It would seem an offense against good literature to wish that they had been less dramatic, less interesting and more true to conditions. The arguments advanced as explanation for the recent murders are mere dalliance with criminality.

The Commission recites that back at a date not named "Profit was the sole object" in mining. That is an indictment of nearly all enterprise today and of nearly all labor also. Few indeed are the mines and few the factories that are opened without profit as a motive. Also few are the workers who work for service and not hire. The report adds, "The life and health of the employees was of no moment."

Perhaps there was a degree of indifference then in the mines of Williamson County, but there is every reason to believe that the attitude as to life and health was not greatly different from that in other industries in that generation. We do not recall any care for these matters till recent years. As Ida Tarbell well says, accidents and sickness were then believed to be the "will of God" or were dismissed with a shrug of the shoulders and the words, "His turn had to come."

The declaration that "men worked in water half way up to their knees" probably is, in the main, hyperbole. It is true doubtless that working places were wet and probably in traveling along roadways water thus deep might be found and have to be traversed, but a miner could not conceivably undercut his place in such deep water. A pumper might often have to wade water even deeper, often did in other places than Herrin. It did not, however, in other regions move him to murder defenseless men.

Gas-filled rooms and bad ventilation, as the Commission says, also existed and not in Herrin alone. But they do not palliate murder. To argue that they do would be in an officer of law almost equivalent to compounding a felony.

The Commission adds, "There was no workmen's compensation law; accidents were frequent and there was no common ground upon which employer and employees could meet." These conditions do not define either the mines or Herrin. They were universal.

The last complaint is naively written: "The average wage of the miner was from \$1.25 to \$2." If so, they were better paid than the average run of men at that date. In 1892 tannery employees in Pennsylvania were making \$1 a day, building houses and saving money. In 1893 a big employer of mine labor was offered the services of Italian laborers for railroad construction at 80c. per day. He refused to take them, arguing that nothing less than \$1 was a living wage.

In the early nineties wages were extremely low everywhere, viewed from our standpoint, and the wages in Williamson County—a farming region with wretched farms—must have been low also. The miner had no special grievance. The cost of living and the low scale of comfort excused the low wage and in no sense justify the criminal actions at Herrin thirty years later. Their fathers had, in the matter of wage at least, not eaten sour grapes, so why should their children's teeth be set on edge.

As the Commissioner says, wages are higher today and the union gets the credit. "The workmen believe in the union, for they think it brought them out of a

land of bondage into the promised land when their government had been careless or indifferent to their needs."

It is needless to show that all wages, union and non-union, in mining and out of it, in unionized trades and in trades with no union of any kind, have risen considerably since the early nineties. In fact the big increases have come in many cases from a bidding for labor, union men being paid at times more than union rates.

This practice of raising wages would go further if employers did not fear that the union would insist that the special employer or district giving the increase shall continue to pay that increase when business declines and competition becomes sharp. One instance may be recalled where an increase of 3c. per ton given to obtain men has persisted as a differential for over twenty years, making mine operation in that district frequently unremunerative.

Wages are rising partly because money is declining in value and will buy less and partly because the output of the country as a whole per workman employed has increased and the workmen has profited inevitably thereby. Competition for labor, in so far as it has not been restricted by labor trusts—and indeed industrial trusts—has caused wage increases. Where, however, as in the mining industry, a group of workmen has profited for long periods more than others it has been because a union, or labor trust, has caused workmen to pay more for the work of its members than other workmen are paid for their work by the union's members.

The union men, as the Commission says, approve of the union, but we cannot forget that they delight in it and appreciate it because it is their means of overriding other workmen. Capitalists have been known to like a trust because it enabled them to override other capitalists and the consuming public. Still that liking hitherto has not been held a good and substantial excuse for murder by any reputable body of citizens. Certainly no commission of staid and respectable men would ever be found to exalt devotion to a capitalistic trust to a level with patriotism.

On the whole we get more satisfaction from what the union says about the Herrin massacre than can be obtained from the remarks of the Commission. The union says the Herrin murders were not committed by it, for it or for love of it but by Bolsheviks who sought to discredit it. Evidently it takes issue with the Commission on two points: First, it says the murders were inexcusable and, second, they were not the work of the union. Obviously the Commission is badly informed. Both operators and the union condemn the murders, and the miners deny that it was done for the union and so remove the one excuse which the Commission generously advances in their favor.

What troubles the observer is, if the men who did the act were enemies of the union "boring from within," why did the union pay for their defense and work for their release, seeing that the stern hand of the law could be depended upon to remove these borers, if convicted, to places where they would bore no more?

Alas, these dastardly villains who murdered men captured under a flag of truce, it is as useless as it is childish to defend!

THE HARASSED HOUSEKEEPER is inclined to think that the finest sight in the world is anthracite.—*Providence Journal*.

Selecting Equipment for Vertical Shaft Hoisting*

Greater Necessity for Shaft Hoisting Due to Mining of Deeper Seams—Selecting the Drum Shape and the Type of Electric Drive
—Description of Various Types of Hoist Control Equipment

BY M. A. MAXWELL

Island Creek Coal & Coke Co., Huntington, W. Va.

GREATER demands for larger tonnages of coal together with the working out and consequent abandonment of the old, easier developed mining sections increases the necessity for mining seams at lower levels in both old and new fields. As a result hoisting from shafts becomes more extensive.

All hoisting problems vary with each installation, shaft hoist calculations being highly specific and mathematically more involved than those for slopes.

Whenever the depth from which the coal must be raised is beyond the practical limit for conveyor systems or raising a train of cars by the usual slope methods, it becomes necessary to resort to vertical shaft hoisting. In this event balanced shaft hoisting obviously is preferable. This method of hoisting requires a shaft with two compartments, each containing a cage or skip operated from a common drum or two drums clutched together, so that one cage or skip ascends as the other descends. The old standard size of such a shaft was 11 x 26 ft., but many of the latest shafts are much larger, one recently put down in Wyoming County, West Virginia, being 18 x 36 ft. In addition an air and supply compartment often is provided. An economical and much-used arrangement is a double compartment for the main hoist, a single compartment for a man-and-material-hoisting cage, which usually is balanced by suitable cast-iron counterweights, and a space for air supply.

Usually such a shaft will cost from \$200 to \$400 per foot of depth, the wide variation in cost being mostly due to the great variation in the amount of water encountered, as well as to the character of the rock.

After determining the location, depth, size and character of shaft, also the number of tons of coal required per shift, the next problem for consideration is the type of hoist to be used. Since steam hoists, used so commonly in the past, have been superseded almost entirely by electrically driven hoists, we will consider only the latter type of drive. We then have two important hoist and electrical details to consider, namely: (1) Type of drum, and (2) type of electric drive and control.

Drums may be of three types: (a) Plain cylindrical, (b) conical, (c) cylindro-conical. On the plain cylindrical type of drum the rope speed increases from zero to maximum and is continued at its maximum until retardation begins, all on the same radius. On the conical type the acceleration begins on the smallest diameter, and continues as the rope winds up to the largest diameter. On the cylindro-conical type, acceleration usually is accomplished while the rope is on the small diameter of the drum, which is long enough to carry the requisite number of turns to complete the acceleration; the climbing of the cone being

accomplished in the fewest practicable number of turns, and the balance of the rope being wound on the large cylindrical part of the drum. On this type of drum the acceleration and retardation periods usually are made the same for the sake of convenience.

The proper and most economical type of drum is readily determinable by calculation from the known data for each specific installation, and hoist specialists are available for the prospective purchaser in the organizations of the electrical and mechanical manufacturers of hoist and control equipment. The selection of the proper drum shape is very important, as it greatly influences the load diagram.

DECIDING THE METHOD OF HOISTING

Before the drum shape and several other details can be definitely decided upon a decision must be made whether the "skip" or the "car-and-cage" system is to be used. In the former, the coal is dumped in storage bins at the bottom of the shaft, and skips holding usually between 8 and 16 tons are hoisted in balance. In the latter, cages holding from one to four cars have been used in this country, the single car cage being by far most common. The arguments in favor of the skip are that on account of large capacity, slower-moving and less expensive hoisting equipment may be used, and that consequently there is less wear and tear, and less repair expense. Advocates of the car-and-cage system assert that the extra dumping at shaft bottom breaks the coal, reducing the amount of lump available for the market, and that the extra cost of underground work, for skips and bins more than balances the extra cost in hoist equipment for the car-and-cage system.

The next important decision is the type of electric drive and control. If conditions demand the use of the skip, or even the car-and-cage system up to a certain rate of hoisting, the geared induction motor drive is feasible. If a rapid hoisting cycle is necessary, the direct-current Ward-Leonard control becomes necessary. The different systems of electric drive are as follows:

- (1) Induction motor with:
 - (a) Master controller, contactors and secondary grid resistance.
 - (b) Primary contactors, and secondary grid resistance.
 - (c) Drum controllers and secondary grid resistance.
- (2) Ilgner-Ward-Leonard system.

Direct-current shunt-wound motor operated from motor-generator set, with flywheel, by Ward-Leonard control.
- (3) Ward-Leonard System.

Direct-current shunt-wound motor operated from motor generator set, without flywheel, by Ward-Leonard control.

*Paper to be presented at meeting of West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, at Huntington, W. Va., Oct. 19 and 20.

FIG. 1
Cylindro-Conical Drum

This installation shows a cylindro-conical drum driven by a large induction motor. Note the chain drives between the motor and drum.

By far the greater number of installations in this country are of the first class, and run as high as 1,800 hp. in motor capacity. They are simple in construction, comparatively inexpensive, and the availability of alternating-current energy at reasonable rates in almost all coal-mining localities favor its selection.

The disadvantages are inherent, as in secondary resistance control the speed varies greatly with the load for any given resistance value. This prohibits great accuracy of control, and in the case of high-speed hoists, which require great precision and accurate control at the ends of trips, its use is subject to restrictions. Up to 100-hp. it usually is possible to use drum controllers for both primary and secondary circuits, handling reversing primary and secondary currents directly on the segments.

The larger sizes demand magnetic control—that is, contactors are used for both primary and secondary circuits in connection with grid resistance. For the largest sizes, primary reversing contactors are used with a “liquid rheostat,” the resistance being in the form of a liquid, usually sodium carbonate, and its value is changed by varying the level of the liquid in a chamber in which are placed electrodes connected in the secondary circuit. Standard voltages for the above equipment are 440 and 2,200, the latter being recommended for 300 hp. and upward.

In the Ward-Leonard system of control the voltage applied to the direct-current hoist motor, and therefore its speed is varied by changing the field strength of the direct-current generator of the motor-generator set which furnishes power to the hoist motor. By reversing the field connections of the generator its polarity is reversed and consequently the direction of rotation of the hoist motor, which latter operates constantly at full field strength.

The excitation for both the hoist motor and the generator fields is furnished by an exciter with voltage regulator control, this exciter usually being direct connected to the motor-generator set. Since only the

generator field current is manipulated in controlling the hoist motor speed the currents are small, and a large number of steps easily may be provided.

The principal factors which justify the selection of the Ward-Leonard control are as follows:

- (a) Accuracy of control; desirable for high speed hoisting or frequent shifting.
- (b) Increased safety in operation.
- (c) Higher efficiency at certain duty cycles.
- (d) Practicability of limiting the maximum power demand.
- (e) Possibility of elimination of gears.

In contrast to the induction motor the speed-torque curves show a comparatively slight change in motor speed over the entire load range on any particular controller point. It is in this respect that its superiority over the induction motor is most valuable. Complete control from standstill to maximum is provided for all values of load. It is rarely necessary to use mechanical braking at all, for in retarding, as the control lever is moved back toward neutral, on account of the inertia of the moving parts, the functions of the machines automatically invert. The hoist motor counter e.m.f. overcomes the applied generator voltage, and becomes a generator, the generator of the motor-generator set becomes a motor, and as such delivers energy into the set until its speed rises slightly above synchronism, when the alternating-current driving motor begins to pump energy back into the supply lines and carries some of the line load. This action brings the hoist drums gently to rest at the stopping point.

If an unbalanced load be lowered down the shaft, it is still unnecessary to use the mechanical brakes, as the descending load acts as a prime mover and sends its energy in to the power lines, falling at a speed determined by equilibrium between its own force and that delivered to the lines. This manner of retardation and the handling of negative loads relieves the hoist mechanism of shock and strain, prolongs its life,

and eliminates brake wear, the brakes being used only for special stops.

When power is purchased under contract carrying penalties for excessive "peaks" or "demands" or generated by the coal company itself under conditions which will not permit the high acceleration peak loads of the hoist, some method of limiting these peak loads may become economically necessary and highly desirable. This may be accomplished by the use of a flywheel direct-connected to the motor-generator set, with a device for automatically varying the speed of the flywheel motor-generator set through secondary rheostatic control of the slip-ring induction-type driving motor. This is the Ilgner-Ward-Leonard system. By its use it is possible to limit the "maximum demand" from the supply circuit to a definite predetermined value for any given hoisting cycle. Whatever energy is required by the hoist in excess of a predetermined maximum limit is taken from the flywheel which gives up a part of its energy as its speed reduces. During periods of lighter power demand the speed of the set automatically increases and energy is thereby stored up in the flywheel and other rotating elements of the set, ready to carry the next peak load.

This peak-limiting control usually is accomplished by the use of liquid rheostatic control of the secondary alternating-current motor currents. Primary current coils are inserted in the main stator leads of the

FIG. 3—HOISTING CYCLE OF HOIST AT MINE NO. 21.

The hoisting equipment for this hoist is quite similar to that used at Mine No. 20. The ratio between the hoist motor output peaks and the input to the motor generator set is not so great as that for the hoist at Mine No. 20 because of the slower hoisting speeds and smaller drum.

motor of the flywheel motor-generator set. Secondary coils from the primary current coils connect to the windings of a small "torque motor," which has a long lever arm attached to its rotor, with rheostat electrodes at one end and counterweights on the other. Whenever the input to the main driving motor tends to exceed a certain predetermined maximum value, the torque of this small regulating motor overcomes the counterweights of the moving parts of a slip regulator and pulls its electrodes apart, thereby inserting more resistance into the rotor circuit of the induction motor of the flywheel set.

Since increasing the resistance in the rotor circuit of a slip-ring induction motor reduces its speed, it follows that the flywheel must give up part of its stored-up energy, because its sustaining force has in a manner of speaking slipped out from under it, and this energy thus released by the flywheel carries the direct-current generator over its maximum output peak, which of course is during the acceleration period of the hoist.

Immediately this extraordinary demand has ceased, the driving motor, having been relieved of its load and consequently taking less current from the lines, is speeded up again through the action of the torque motor in bringing the electrodes nearer together, which through weakened torque now permits the weights to overcome it. This speeding up of the main driving motor restores energy to the flywheel. In this it is assisted by the action of the generator during the retardation period because the hoist in effect acts as a motor and drives the flywheel.

This control is so positive and accurate in its operation that when operating on the cycle for which the hoist is designed, and for which the control is adjusted, it is possible to maintain practically constant input to the flywheel set. Five per cent either way from average is guaranteed by the manufacturers. This control also functions when starting the set, thus holding its starting peak within the limit.

In this system it will be observed that the torque required for acceleration is built up gradually from

FIG. 2—HOISTING CYCLE OF LARGE MINE HOIST AT MINE NO. 20, ISLAND CREEK COAL AND COKE CO.

Note how the power drawn from the power line does not vary with the peaks on the hoist motor.

FIG. 4

4,000-H. P. Hoist

On heavy vertical shaft duty. Frequently we think that all large motors are made for operation on alternating current, but here is one that operates on a large direct-current hoist.

zero to normal by varying the voltage so that the required power for acceleration is much less than in the case of the direct-connected or geared induction motor drive, where the power is thrown on in full force and remains so during the entire acceleration period. This characteristic permits the operation of a large hoist from a small power station, which must supply a steady voltage for other loads.

In ordinary practice, by the installation of suitable apparatus, the "maximum demand" can be held to less than one-half the hoist motor's acceleration peak. Aside from a financial saving thus effected, in the power bill, an important result of this leveling out of the hoist load upon the power lines is the elimination of violent fluctuating voltage surges upon the supply lines. If, as is often the case, the mine developments are located at some distance from the power company's step-down substation and the same power lines carry rotary-converter loads, such fluctuations seriously affect the conversion, causing severe variation in the direct-current mine voltage.

All the above systems are equipped with safety devices of the most positive action. Due to the cooperation between hoist and electrical manufacturers the complete hoisting equipment may be made practically "foolproof," even to the cages or skips, which stop instantly by gripping the guides in case of cable breakage.

Ward-Leonard systems, which do not include the use of flywheels, are driven either by synchronous or squirrel-cage induction motors, choice being based on considerations of first cost, power-factor regulation desired, pull-out torque, etc. The general scheme of control is similar to that of the Ilgner-Ward-Leonard system, excepting that, no flywheel being used, the slip regulator is unnecessary.

The Island Creek Coal Co., with mines at Holden, Logan County, W. Va., has installed during the past year a total of four shaft hoists, two for coal and two for men and materials. A brief description of them may prove interesting.

The famous Island Creek seam lies in a huge syn-

cline on a part of the property. Above creek level on the adjacent lease to the south it dips several hundred feet, appearing again above creek level part way across the Island Creek property, where it has been worked for years. Since the low portion of the seam is from eight to ten thousand acres in area and is from $6\frac{1}{2}$ to $7\frac{1}{2}$ ft. thick, the company desired to work it over its entire area. Borings indicated two very favorable points for development, one toward the head of Whiteman's Creek, at an approximate depth of 300 ft., the other toward the head of Trace Fork at a depth of approximately 200 ft.

Since the proven areas showed somewhere between eighty and one hundred millions of tons of minable coal, plans for a large ultimate capacity were considered desirable. Hoisting equipment capable of raising at least 500 tons per hour was required. At each location two shafts were sunk. The main shafts are $12 \times 27\frac{1}{2}$ ft. with circular ends, and the supply shafts are $12 \times 29\frac{1}{2}$ ft. The former have two compartments for balanced hoisting, the latter a single compartment for a supply cage, a narrow space for counterweights, and the balance of the area for air supply.

On account of the special quality of Island Creek coal for domestic use, it was decided to avoid as much breakage as possible, so the car and cage system of hoisting was chosen, each compartment of the main shaft carrying a cage equipped to hold one mine car of two and a half tons' capacity. The cage is arranged to tip automatically at the top, so as to dump the car without its removal, thus saving time in unloading and wear and tear on the cars.

For the man-and-material hoists, herringbone-gear plain cylindrical drums of a diameter of $6\frac{1}{2}$ ft., driven by 200-hp. induction motors were found suitable, and the control equipment is full magnetic with primary contactors and secondary grid resistances. Since the Trace Fork man hoist was put in operation it has raised approximately 10,000 tons of coal per month, pending the completion of the main hoist installation, in addition to handling an immense amount of material used for development, including the removal of slate and lowering

of masonry material for the finishing of the main archways at the bottom of the main shaft.

The selection of the main hoists called for thorough investigation during which it developed that we could not hope to attain the rapid hoisting cycle necessary for the required output through the use of alternating-current control. Another serious disadvantage with this type of drive and control would have been the impossibility of limiting our maximum demand, which with its cost of \$1.80 per kilowatt per month based on the five-minute integrated peak, would have been expensive and would have had a bad effect on our rotary installations.

The final hoist calculations showed that the duties required the use of the Ilgner-Ward-Leonard system, with the use of cylindro-conical drums of 7 ft. at the small diameter and 10 ft. at the large diameter driven by direct-current motors, direct-connected to the drum shafts. The following duty cycles were calculated, and the tabulation will show the conditions to be met at each location. System of hoisting: Balanced, double compartment, car and cage.

DUTY CYCLES	Mine 20	Mine 21
	Whitman's	Trace
Total vertical lift.....	370 ft.	280 ft.
Weight of cage.....	12,000 lb.	12,000 lb.
Weight of car.....	3,400 lb.	3,400 lb.
Weight of coal per trip.....	5,000 lb.	5,000 lb.
Rope diameter.....	1½ in.	1½ in.
Weight of rope per side.....	1,110 lb.	840 lb.
Maximum speed of drums.....	82.5 r.p.m.	63 r.p.m.
Time to accelerate.....	4 sec.	4 sec.
Time at full speed.....	5 sec.	5 sec.
Time to retard.....	5 sec.	5 sec.
Time to dump and load.....	4 sec.	4 sec.
Maximum number trips per hour.....	200	200
Short tons per hour.....	500	500
Assumed WR^2 of drums.....	500,000 lb.	400,000 lb.
Turns on small diameter of drum.....	2.75	2.1
Turns on cone.....	3	3
Assumed mechanical eff. hoist part.....	80 per cent	80 per cent

The complete hoisting cycle is 18 seconds, including the rest period, which fulfills the capacity requirements. WR^2 represents the inertia of the moving parts of the hoist, sheaves, etc., and is expressed in foot pounds, and must naturally be taken into consideration in figuring the required power for acceleration.

In the accompanying load diagrams, Hoist A, located at Mine No. 20, represents that at Whitman's Creek; and Hoist C, located at No. 21, represents that at Trace Fork. They afford an excellent illustration of the great difference in power requirements for the same capacity in coal taken from different levels.

Though the total lift at Mine No. 20 is only 90 ft. greater than that at Mine No. 21, the distance being 370 ft. and 280 ft. respectively, it will be observed that the momentary acceleration peak at Mine No. 20 is 1,270 hp., while at Mine No. 21 it is only 670 hp. This is on account of the fact that in order to obtain the same time for the hoisting cycle it is necessary at Mine No. 20 to accelerate from rest to a rope speed of approximately 2,600 ft. per minute, in exactly the same number of seconds that a rope speed only 1,900 ft. per minute is reached at Mine No. 21, these figures being the maximum rope speeds respectively on the two hoists.

It may be of interest to know that the selection of the hoist and control was influenced by considerations of economy in electrical energy, there being a saving of approximately 20 per cent in the kw.-hr. required for hoisting one ton of coal, the power consumption being 0.49 kw.-hr. at Mine No. 21, and 0.60 kw.-hr. at Mine No. 20.

The distribution voltage of the power supply over the Holden property being 6,600 volts, 3 phase, 60 cycle, the

motors of the motor-generator set operate at line voltage, the final capacities of the motor and generator for the main hoist being as follows:

	Mine No. 20	Mine No. 21
Capacity 6,600-volt driving motor.....	450 hp.	350 hp.
Capacity D.C. shunt wound generator.....	700 kw.	400 kw.
Weight of steel plate flywheel.....	13,000 lb.	9,500 lb.
Capacity 250-volt exciter.....	19 kw.	19 kw.
Voltage of D.C. generator.....	400	260
Capacity D.C. hoist motor.....	900 hp.	475 hp.
Synchronous speed of set.....	900 r.p.m.	900 r.p.m.

Commutating poles insure sparkless commutation on both generator and motor at all loads. Since the sole work of the generator is to drive the hoist motor or to be driven by it, any voltage may be chosen provided the amperage is held within reason. It was possible to use standard frames for both generators by using 400 volts at Mine No. 20 and 260 volts at Mine No. 21.

The supply hoists and rotary substation equipments are in separate rooms in one building, while the motor generator sets and main hoists are in separate rooms in another building.

The power circuit supplying the two developments is in the form of a closed loop about eight miles in length, and of No. 00 copper from a step-down substation at Whitman's Creek Junction. Switching towers at each mine permit feeding from either end of the loop. Separate circuits are taken off the towers through separate disconnecting switches to the main hoist, supply hoist, and a local substation. The towers also are equipped with choke coils and surge lightning arresters.

Germany Has Limited Reserves of Lignite

THE German publication *Braunkohle*, in the issue of May 26, gives the following record of the reserves of lignite in Germany, basing it on the Geologic Service of Prussia, which finished its labors on this survey in December, 1922. That survey reports the reserves, actual and probable, not exceeding 1,000 m. or 3,281 ft. in depth, to be as in Table I.

TABLE I—PROBABLE RESERVES OF COAL NOT EXCEEDING 1,000 M. IN DEPTH IN THOUSANDS OF TONS

Districts	Operable by Open Cut	Operable by Underground Mining	Total
Lower Rhine.....	2,315	1,382	3,697
Westerwald.....	105	105
Upper Hesse.....	1	7	8
Lower Hesse.....	37	124	161
Brunswick-Magdeburg.....	299	1,311	1,610
Thuringia-Saxony.....	2,733	1,704	4,437
Lower Lausitz.....	568	4,656	5,224
Upper Lausitz.....	875	947	1,822
Oder.....	40	431	471
Totals.....	6,868	10,667	17,535

In determining the list of the beds operable by striping, all those beds are included the thickness of the overburden above which lies between one and two and a half times the thickness of the utilizable part of the coal bed. An allowance for loss in mining of 30 per cent for work above ground and of 50 per cent for work below ground has been made.

If to the figures are added those from other states than Prussia, the total reserve will be nearly 21,900,000 tons. It is well to add that this reserve represents only 2.8 per cent of the total combustible mineral reserves of Germany when taking into consideration the calorific power of the respective minerals.

IN THE EVENT that Governor Pinchot would like to take another conciliation job or two, the world was never in position to offer him a larger assortment.—*New York Evening Post*.

How Permanent Records of Mechanical and Electrical Equipment May Be Kept*

Advantages of Equipment Records and the Co-operation Needed to Maintain Them — How Different Types of Machinery Are Classified — Permanent Inventory Made Possible — Records as a Guide for Purchasing New Equipment

By J. H. EDWARDS

Electrical Engineer, Elkhorn Piney Coal Mining Co.
Huntington, W. Va.

THE necessity of having complete descriptive records of all machinery and equipment in use and held as spares at every coal mine is obvious. However, it may be interesting to enumerate some of the advantages of such records.

When a new man, such as a superintendent, mine foreman, mine electrician or chief electrician is employed, these records will afford him an easy and quick method of learning with just what equipment he will have to deal. When, as often happens, the manufacturer's nameplate is lost, that valuable information is preserved by the record.

When repair parts are ordered the records save the time and energy of making a trip to the machine to get a copy of the nameplate information and eliminate mistakes, for guesses are not made and no errors arise such as are to be expected when an attempt is made to read dirty or battered nameplates.

The records afford a place to note important changes to parts of a machine, which affect the proper ordering

NAME PLATE DATA

(Copy items in same order—include repair parts—omit patent dates)

(No name plate on boiler)

Equipped with Foster Superheater No. S4344
Built by Power Specialty Co.

Superheater is made up of 23 sections or units
Boiler tubes arranged 13 rows high, 7 rows of 15 each and 6 rows of 14 each.
The 22 extra tubes on hand 11/29/19 are 18' 11-3/4" long and measure 3.97" OD and 3.65 ID.

Note: Fire brick arch replaced 2-18-21, used fire brick which were left over from original power house construction; cost Material \$200.00; labor carpenter \$8.37; brick mason 16 hours \$20.00; common labor \$12.20; miscellaneous \$4.92; Total \$245.49.

Note: Detrick arch installed 7-20-22. P. O. 17190, dated 5/31/22. Arch \$274.00, freight on arch \$13.36, 1000 fire brick \$48.00. Other material including 400 lbs. of J-M No. 31 high-temperature cement \$25.69, labor \$62.98, total \$424.03

FIG. 1—BOILER REPAIR DATA

Costs of maintenance and record of materials and labor are easily kept on each piece of equipment.

FIG. 2—CLASS "C" RECORD

Complete nameplate data are quickly available for ordering any part for this coal-cutting machine.

of repair parts. They also afford a place to record the date when the equipment was purchased, the order number, the name of the company from whom it was purchased, and its original cost.

In case of a breakdown records enable those in charge to make a quick and sure survey of the situation and to determine the possibility of transferring other equipment so as to relieve the situation. The records, if properly maintained, are a perpetual inventory of the mechanical and electrical equipment.

Where a company operates several mining plants from a central office the equipment records reduce the time and expense of traveling which would otherwise be expended in obtaining information such as a good record should provide. The records also prevent the loss of equipment lent to neighboring mines.

The system of records used by the Elkhorn Piney Coal Mining Co. was devised to suit the location of the mines with respect to the district and general offices, also upon the method of management of the company.

FIG. 3—D. C. MOTOR DIAGRAM

Aside from nameplate data this record shows the important motor connections.

In consequence, a brief outline of these conditions may be necessary. The various mines are grouped into several divisions situated in eastern Kentucky and southern West Virginia; the offices of the manager and also the electrical engineer are located at Huntington, W. Va. The main offices, including that of the purchasing agent, auditor and vice-president in charge of operations, are at Milwaukee, Wis. Each of the larger operations has a man whose duties include those of chief electrician and master mechanic of that division. This arrangement calls for three complete copies of each set of records, one for the chief electrician at the mines, one for the electrical engineer at Huntington and one for use in the main offices at Milwaukee, Wis.

The electrical engineer is in charge of the equipment records and therefore is responsible for the proper recording of all new equipment purchased and also for making any alterations or additions to the record sheets of old equipment. The permanent copies of record sheets of all new equipment are prepared in his office, which also sends out all instructions regarding any changes to be made on the records.

This arrangement requires the co-operation of the chief electrician at the mines, who must keep the electrical engineer advised of any changes which are otherwise unknown to him. This method makes it possible to have a uniform system of records at each operation, also to maintain the three copies of each record for the three respective offices.

The record sheets measure 8½x11 in., that is, of letter size. They are punched for filing in standard loose-leaf binders. This overcomes the common objection to the card system, where it is so often found that for certain items of equipment the cards do not afford sufficient space to hold all the desired data. Also, the

fact that the sheets are filed in ring binders makes it more likely that the records will be kept in proper index order. A further advantage of the large sheet over the card is that several copies of a record can be made at one typing.

On the front of each sheet is a form suited to the equipment being recorded, and on the back are spaces for nameplate information. By thus providing for a complete copy of the nameplate data the record sheet will afford information which a fixed form cannot always provide. The front upper right-hand corner has a space headed "Equipment," in which is inserted in one or two words the type of equipment: for example, "DC Motor" or "Transformer." This makes it much easier to locate the record sheet of any particular class of machine.

Near the top of the form is a space headed "Descriptive Name," opposite which is inserted in a few words a description making it possible to quickly identify a certain piece of equipment from others of about the same type. Space is allowed for purchase order number, date and cost. This information often is required by the operating department, and is invaluable to the auditing department as a perpetual inventory. Several spaces are allowed for recording transfers from one operation to another. At the bottom is a space headed "Out of service or destroyed." Notations are made in this space whenever machinery is sold, destroyed or scrapped.

These forms divide into eight different classes, namely B, C, E, F, L, M, P, and S. The principal items of equipment which are recorded in each class are as follows:

Class B—Steam boilers (all types except those on steam-railway locomotives), feed water heaters, steam separators, feed water meters.

Class C—Coal-cutting machines.

Class E—Alternating- and direct-current motors, transformers (not including instrument transformers), generators (not including direct-connected units), converters, motor-generator sets, switchboard panels, large automatic reclosing circuit breakers, automatic

The Deming Company,
Manufacturers
Salem, Ohio
Fig. 70 Size 5½ x 8"
Pump No. 15888

Note: Gear reduction motor to pump crank shaft is 20.013 to 1.
Motor pinion 20 teeth, 3-1/4" face, 1-5/8" bore, 3/8"
x 3/16" keyway, 3 pitch.
Intermediate gear 79 teeth, 3-1/4" face, 2" bore, 1/2"
x 1/4" keyway, 3 pitch. Intermediate pinion 15 teeth,
3½" face 2" bore, ½" x ½" keyway, 2½" pitch.
Crankshaft gear 76 teeth, 3½" face, 2½" pitch, has a large
bore and is bolted to crank disc of crank shaft.

FIG. 7—BACK OF PUMP SHEET

Important gear data are shown complete. In consequence there is no likelihood that a gear will be purchased that is either too small or too big. Incorrect pitch is a frequent cause of broken shafts.

the manufacturer's guaranteed performance of a mine fan. By being on the record sheet, this data will be preserved where it will be most convenient to locate.

Fig. 5 shows the record sheet of a pipe-threading machine which was sold; a notation to that effect has been added to the bottom of the sheet on the line headed "Out of service or destroyed." The mine pump, Fig. 6, was transferred to another operation. This transfer is indicated in one of the spaces below the heading "Transferred to." Fig. 7, which is the back of the record sheet of this same pump, indicates how information regarding the gears and pinions has been included.

No matter how complete a set of equipment records may be they will not be used to the best advantage unless they are properly indexed. The index for the above record system was given particular attention. A regular printed form, of the same dimensions as the

record sheet, is used. Fig. 8 is a sample of the index of Class C equipment at operation No. 4. Opposite Record No. C-3 will be seen notes indicating that this mining machine has been transferred to another operation. Opposite Record No. C-12 are notes showing that this mining machine has been scrapped. The items C-36 and C-59 were originally recorded at another operation and then later transferred to operation No. 4.

These last items are spaced so as to allow room for any other numbers which might be transferred to this operation in the future. It was formerly mentioned that each operation was assigned a certain range of numbers in each class in order that there might be no duplicate numbers. This is illustrated by the items C-36 and C-59, which were transferred from operations where the ranges allotted included these numbers.

From this sheet the life of the battery can easily be determined and future purchases economically guided.

in use, its main purpose is to afford a means of determining the actual service cost per year of the various makes and sizes of batteries. This experience serves as a valuable guide in the purchase of renewal batteries. These battery records are not kept as a part of the regularly indexed equipment record because, unlike other equipment, batteries have a life averaging only one to four years and consequently must be renewed much more frequently than the other mechanical and electrical equipment.

FIG. 8—INDEX SHEET FOR CLASS "C" EQUIPMENT

Proper filing is highly necessary, otherwise a perfectly recorded piece of equipment may be overlooked when making use of the records.

What the Exhibitors Had to Show at American Mining Congress and National Safety Council

Electric Safety Cap Lamps of High Candlepower—Means for Self-Rescue—Steel Car for Anthracite Region—Mechanical Loading—Safety in the Presence of High-Voltage Electric Current

NOTABLE both as to the number of its exhibits and their scope was the Annual Exposition of Mines and Mining Equipment at Milwaukee, Wis., in connection with the annual convention of the American Mining Congress, Sept. 24-29. Much of the equipment and many of the devices were not by any means new to the industry. Only the newer ones have been selected for description in this article. The Mine Safety Appliances Co. exhibited its new Edison safety cap lamp in which the electrolyte is kept from escaping by valves which are closed by the shutting of the battery-box cover. This provision prevents the escape of the electrolyte, so that even with the lamp reversed and shaken none of the fluid escapes. This new lamp gives three times the light of the older model of the same lamp, and the bulb is so mounted that the rays of light are entirely unobstructed.

The lamp weighs 5 lb. 3 oz. and gives an average light flux of 9.67 lumens, or a total of 116 lumen-hours during a period of 12 hours burning. The mean candlepower of the light stream from the headpiece over a period of 12 hours is 2.67. The average current consumption of the bulb for the same period is 1.06 amperes.

HAVE OVER TWICE PREVIOUS POWER CAPACITY

The cells have $2\frac{1}{2}$ times the ampere-hour capacity of those they replace and yet occupy approximately the same size of casing. The headpiece is sealed so that the miner cannot open it and is so designed that bulb replacements may be made without disturbing or touching the reflector or removing the lens. The bulb has

a concentrated filament and consumes a relatively high current. The lens is laminated, being made up of two thin pieces of glass with celluloid between them. The cord is of the spiral type protected by a heavy rubber coating.

The voltage of the battery at starting is 2.81 and after ten hours is still 2.28. The candlepower at the center of the light stream is 5.12 and at an angle of $32\frac{1}{2}$ deg. 4.10.

Another exhibit by the same company was a self-rescuer. In earlier

days it was thought necessary to give the mine worker an apparatus that would supply him with oxygen. The new self-rescuer does not afford him anything but merely intercepts all the many poisonous gases and fumes with which the baleful afterdamp is filled, except carbon monoxide. This latter gas it combats by converting it into carbon dioxide, which is harmless. This self-rescuer, which may have to be kept or carried for long periods of time without its bearer having any use for it, is placed in a box having a cover which is provided with a seal of soft lead of such a character that the cover readily can be torn off by the mine worker and the self-rescuer taken from the box.

It is necessary thus to protect the apparatus, as the entrance of moisture, if long continued, would destroy the power of the Hopcalite, by which the monoxide is converted to dioxide. All the mine worker has to do after he has opened the box in the manner already described is to adjust the nosepiece and put his mouth over the rubber connection provided for that purpose. The self-rescuer weighs 13 oz. including the box and can be carried in the pocket or on the belt, for it measures only 4x8 in. over all.

A shotfirer in Mine No. 49 of the Central Coal & Coke Co., Pittsburg, Kan., recently became involved in an explosion resulting from a blown-out shot. He had a self-rescuer with him, fortunately, and with its aid found his way to the surface.

At its booth in the exposition the Mine Safety Appliances Co. also showed a timber jack with a screw stand. This stand supports a Y which is used for holding up a cross timber till it can be secured in place. The device is said to save labor and reduce accidents.

The Lorain Steel Co. exhibited the Lehigh Coal & Navigation Co.'s new car, all of steel, with spring draft gear, single springs over journal boxes and intended for rotary dumping. In general it is of the pattern usually associated with the anthracite region. Thus it is 5 ft. $\frac{3}{4}$ in. high; and why not, seeing it is to be loaded by chutes? Its over-all width is 5 ft. $6\frac{7}{8}$ in. and over-all length 9 ft. $4\frac{1}{2}$ in. It weighs 5,600 lb. when empty and it holds 116 cu.ft.

On the stage thundered a Joy loading machine, now equipped for use with both caterpillars and wheels for use as the operator may wish. The caterpillar runs between the tracks. Should you desire to put on wheels, put two ties between the tracks behind or in front of the caterpillars and move toward them. The caterpillar will climb on them and lift the machine so far above the rails that wheels can be slid on the axles. As soon as the caterpillars have passed the inserted ties, the wheels, if put on, will engage the track so that the loading machine will travel on the wheels instead of on the caterpillars and can be taken in this manner to the next working place, provided that is the preferred way of traveling.

Gages of 42 in. and upward are equipped with de-

SELF RESCUER FOR MINES

Experiments during the war led to the invention of this self-rescuer, which if devised earlier might have saved many lives.

Steel Car for Anthracite

This car is intended for loading from chutes and for discharge by a rotary dump. It will be noted that it has springs over the journal boxes and spring draft rigging.

tachable track wheels for transporting the machine from one working place to another. On narrow gages the caterpillars are set to the track gage to permit the calks provided in the tractor treads to function as wheel flanges restraining the machine so that it is compelled to travel along the mine track rails.

Where the cross-sectional area of roadways is restricted it becomes necessary to use on storage-battery locomotives smaller batteries than are well suited for a day's work, and in other cases where the work is particularly heavy the cells do not retain enough of their strength to keep the locomotive traveling at speed the day long. At such times the batteries have to be boosted or charged. The change as usually performed is an operation involving time and labor, and the Mancha Storage Battery Locomotive Co. has devised a way, which was exhibited at the company's booth in the Exposition, whereby the change can be made in three minutes.

A pedestal track is placed at such a level that when the locomotive strikes it the battery in its case is lifted from the chassis of the locomotive and supported so that the latter can be backed out of position. The raising of the battery is performed by an inclined plane, the track on which the battery runs during the first part of its travel being inclined uphill. From another similar track the locomotive thus stripped can obtain another battery and go again to its work with all the vigor of a fresh charge.

The battery left on the pedestal track can be charged without removal and will be ready to be loaded on the chassis as soon as the locomotive has demounted the other battery. It is urged that this ability to transfer

the battery promptly adds 100 per cent to the work that the locomotive may be expected to perform.

At the booth of the Falk Corporation was shown a flexible coupling invented by James Bibby, of England, and first manufactured in that country. It is known here as the Falk-Bibby coupling. With any shaft it is important that the bearings be all in line. When a shaft has only two bearings good workmanship should provide that need, but with more bearings than two the alignment may not be so perfect. Even though that alignment may have been exact when the shaft was installed the supports under the bearings may settle and as a result the shaft may be subjected to additional stresses and the bearings to increased friction, thus causing a continuous loss of power and undue wear.

For this reason alone a flexible coupling is desirable, but it has the further advantage that any shocks received by the operating parts are not transmitted to the motor. A coupling should not transmit torsional oscillations, and between shafts there should be no end thrust.

The Falk-Bibby coupling consists of two flanged steel disks, one keyed to each shaft, and a tempered steel spring encircling both and forming a continuous cylindrical grid and a shell. On the outsides of the flanges are pitched cross grooves. In these the spring is placed, connecting the two disks but in an elastic manner. The grooves in the disk widen inward toward each other, so that the spring fits closely in them only at their outer ends. This widening is in the form of an arc of definite radius. It is made by machines specially designed for that purpose and the radius of the arc is such that each bar of the spring can be bent around this radius without exceeding a fixed safe stress.

Consequently under heavy loads the spring members become supported along the sides of the grooves, thereby automatically shortening the spring without increasing the stress. Under extreme overloads the springs are in shear and can resist many times the load for which the coupling is designed.

One of the most active pieces of machinery in the exposition was a Hoar "Baby" shovel for underground loading. In the hands of an operator it went through the motions of dipping, crowding, hoisting, swinging and dumping with astonishing agility and much sputtering of compressed air. This machine, well known for years in hard-rock regions, is entering the coal field as a serious contender wherever a mine is equipped with compressed air. It is exceedingly compact.

A medium sized type—shovel No. 2—needs but 7 ft. of clearance, top and sides, can clean up an area 14 to 16 ft. wide and is said to be able to load 200 tons of

Taking on a Live Battery

A locomotive may be good for the day's work even when the battery is entirely outclassed. This is why means have been provided, as shown here, to remove the battery with minimum loss of time and replace it with one having a full charge.

FLEXIBLE COUPLING REDUCES STRAIN AND FRICTION

The two shafts to be connected have disks which are slotted and in the slots are laid a spring which connects the disks. As the slots do not fit tightly over the full depth of the spring, the attachment is elastic and shocks are not transmitted from the machinery to the motor.

coal in an 8-hour shift with a good turn of cars. The machine can be motor equipped, but more headroom would be necessary for its operation.

The Hoar Shovel Co., of Duluth, makes the shovel in a larger and a smaller size than the one displayed. The smaller one is a marvel of compactness, operating in a space measuring but 5 ft. 6 in. but with a breast capacity of 12 ft. The total weight of all three types is small—6,300 lb., 6,000 lb. and 5,700 lb. and any one of them can quickly be disassembled to be lowered or hoisted through a 42x42-in. shaft.

A spring reel for power or light cable was shown by the Appleton Electric Co. In the smaller sizes this device has its best coal application in the mine-repair shops. By its use a lamp, drill, or any portable tool can be carried around the work, only the length of cable necessary being paid out by a ratchet arrangement inside the housing of the cable reel, which latter is fastened at the electrical outlet. This device is expected to reduce the wear on cables and keep troublesome lengths of it out of the way.

At the Twelfth Annual Safety Congress, held in the Statler Hotel, Buffalo, N. Y., Oct. 1-5, a small exhibit was provided. W. H. Salisbury & Co., Inc., presented an extremely satisfactory line hose to take the place of the rubber blanket in protecting the lineman. This hose requires no clamps and the far end can be run out on the line beyond the reach of the lineman; a patented locking device keeps the hose everywhere

around the electric conductor. It is as easy to detach as to apply.

Linemen's rubber gloves also were exhibited. They were made with a pure-gum center, the whole glove being 95 per cent pure rubber. Seamless and pliable, they meet the need of the lineman when working in difficult places and handling many tools.

The Dayton Safety Ladder Co. presented a line of ladders unusually light and readily collapsible but also more than usually stiff when erected. There are

SAFETY LADDER

Ladder accidents are not specific to the coal industry, but they cause accidents nevertheless.

said to be 20,000 stepladder accidents in industry yearly, so the need for safer ladders is obvious. A large, safe-working platform is provided and even this has side rails, which not only add security but stiffen the ladder. In working about power houses and electrical equipment a safe, stiff ladder is one of the greatest of needs.

The Foamite Firefoam Co. ran a film of its method of fighting fire. Foamite can be used on electric arcs but the company is not pressing its use for that purpose. The first discharge from foamite firefoam fighting equipment is likely to be little other than water. In a few seconds the character of the discharge changes. In consequence if the first discharge is not directed on the arc but on the floor, the results with even 8,000 to 10,000 volts will not be dangerous provided the operator has the usual protection.

However, the Foamite firm is still advocating carbon tetrachloride for that purpose, that gas being a powerful dielectric. The value of foamite for putting out fires in oil tanks is unequalled. In a heavy wind the foamite, depending on a froth that cannot be blown away, works better than any mere gas, however heavy.

Another fire-fighting and fire-preventing medium is carbon dioxide. It is being used for playing on electric fires and experiments are being made to use it in transformers in place of air, as it is a protection against fire not only directly but indirectly also because the oil in the presence of dioxide will not oxidize and lose its dielectric qualities.

Mills Beat Mines at Bethlehem Steel Meet

As the result of a series of spirited first-aid contests in which for a while it looked as if the coal miners would be victors, the Saucon mechanical department of the Bethlehem Steel plant took first place, and Bethlehem was hailed as the winner Oct. 5 at the Broadway Auditorium, Buffalo, N. Y., on the closing day of the National Safety Council's meeting. Earlier, however, four teams of the Marion division had held an elimination contest at Barrackville, W. Va.; the Preston division's ten teams had met at Oak Park, W. Va., and eliminated all but one team; the Ellsworth teams, thirty six in number, had assembled at Ellsworth and by trial had selected two teams; the five Slickville teams had similarly met and ascertained which was the best. Johnstown, which had eleven teams; Wehrum, which had five, and Heilwood, which had twelve, had each selected by contest its crack team. In consequence there were eight representative mining teams which were all sent to Buffalo for the final and semi-finals.

The judges in the final round placed the Bethlehem plant first, Ellsworth No. 1 second, Lebanon (mechanical department) third, and Wehrum fourth. The averages attained by the various teams in the final contest were not published. One coal-mine team in pulling a patient off a live wire let him fall back on it twice, and one of the men in the first-aid team then trod on it in his anxiety to perform his part. One of the doctors present remarked, however, that the work of rescuing the man from the wire was done with much skill, and he could not understand how the patient slipped from the loop.

The patient certainly did his part under the rules and made no resistance to falling back onto the wire. To what extent this accident affected the averages of the team is not known. In the finals a layman and a doctor judged each event.

The winning team gets \$400 and holds the Bethlehem trophy for one year; the second team gets \$200; the third, \$80; the fourth, \$40. Each team contains eight men. The mine corps were trained by J. V. Berry, chief of the safety and first-aid department. J. O. Durkee is chief inspector of mines. At the intermission between the finals and semi-finals a mine-rescue group of ten men gave an exhibition of apparatus work.

Technical Discussions Elicit Deep Interest at Milwaukee Convention of American Mining Congress

Churn Drilling in Strip Pits—What Can Be Done to Get Larger Coal
—Saving Effected in Spare Parts—Battle Between Alternating- and
Direct-Current—Standardization—Fire Doors vs. Reversible Fans

EXCELLENT attendance marked the meetings of the Open Forum of the convention of the American Mining Congress at Milwaukee, Sept. 24-29, especially in view of the fact that every section exceeded its time, and arrangements had to be made to continue in another room the holding of one section during the session of the one that succeeded it.

D. E. A. Charlton, assistant business manager, *Engineering and Mining Journal-Press*, presided over the discussion on "Churn Drills vs. Air Drills for Strip-Pit Work." Mr. O'Connor said in this discussion that churn drills making 6-in. diameter holes and driven by one man were and had been for some time displacing jackhammer drills in the Mesabi region. It was not necessary to shoot a preliminary shot so as to chamber the hole made by the churn drill for it was always of ample size and that was well because chambering made an initial shattering that could not fail to have a deleterious effect when the final shot was made.

Mr. Gardner, of the Sanderson Cyclone Drill Co., said that while six years ago the Mesabi region had but 5 or 6 churn drills, it now has 150, evidencing the inevitable displacement of percussive by churn drills wherever soft material had to be shot. Mr. Rhodes added that the large hole was, as Mr. O'Connor said, the great desideratum as it enabled a large charge to be inserted without chambering and thus shattering the ground.

SHOOTING SO AS TO OBTAIN LUMP COAL

Notable among the discussions was one on "Means of Securing Co-operation from the Miner in Using Explosives That Will Produce a Maximum Quantity of Lump Coal," which was introduced by H. C. Adams, president, Peerless Coal Co. This was the principal feature of the session under the chairmanship of N. S. Greensfelder, editor, *Explosives Engineer*. Mr. Adams is operating in the No. 5 seam in central Illinois. The coal is not undercut by machine but is blown from the solid.

Mr. Adams stated that the men at the mines were no longer miners of experience but mere diggers. They had no desire, what is more, to produce large coal. Fine coal shoveled more easily than large. On the other hand the operators were entitled by contract to have the miners use due care in mining so as to provide a large percentage of lump. That was set forth in the agreements as a duty, the union having inserted that clause at the demand of the operators at the time when payment was made on a run-of-mine basis instead of on a lump basis, removing thereby the anxiety of the miner to produce large coal.

Mr. Adams said that he had believed that he could obtain instructors in mining who could induce his men to abandon their evil practices, which he believed were due to lack of training as much as to indifference, and in many cases resulted in loss to the miner, for the shots did not do what he desired of them and at the

same time used an excess of powder, for which the miner had to pay. His superintendents, however, advised him that any such attempt to modify the miners' methods would be ineffectual. The miners insisted that C.C. powder was too slow. The company contended that even C. powder was too fast.

Mr. Adams said he had sought help from the Department of Mines and Minerals of the State of Illinois and had been advised that two companies, the Silver Creek Coal Co. being one of them, had reduced screenings 10 per cent by instructing its miners. The department did not see itself able to do anything to prevent improper shooting of coal but urged on Mr. Adams that

LEADERS OF AMERICAN MINING CONGRESS FOR 1924

J. F. Callbreath, left, is the veteran secretary, re-elected at the Milwaukee convention to continue his service. H. W. Seaman, right, whose home is in Clinton, Iowa, but whose business interests are everywhere, centering especially at Deadwood, S. D., in the Trojan Mining Co., a successful gold enterprise, was chosen to succeed Sidney J. Jennings, of New York, as president of the Congress. During recent discussions about the possibility of choosing a "dictator" for the coal industry, a thing similar to the "dictatorship" of Judge Landis over baseball, Mr. Seaman was mentioned as a likely man for the big job.

the law made it a duty of the management to supervise the placing of holes—a contention that had not occurred to him and which he had not yet investigated. Mr. Adams said that his company had been producing coal that would have given, if all screened, about 40 per cent of screenings.

A. J. Moorshead, president of the Madison Coal Corporation, said that the question of the proper use of

powder was most important both as concerning profit from the enterprise and conservation of life. At his mines a supervisor of explosives has been appointed. He sees that no wires are installed in magazines and no open lights are allowed to enter, only storage-battery lamps being permitted in such places, that sparkproof powder cars are employed for the transference of powder, that the cars are loaded at points where no circuits could ignite and explode the powder, that powder cars are properly closed when powder is being transported, that the electricity is not only switched off at two switches but locked off also with two keys, each held by a different official.

Shift bosses are employed to see that the drillholes are properly placed, and if not to give advice. Conditions are not getting better, however, but rather worse. Time was when \$2.25 a ton was paid for the loading of pyrite and much of it was loaded, but today with the higher wages paid no one cares to load pyrite. A big enough earning can be made without it. Everyone is in a hurry to load up enough to get a pay that will suffice for a day and then go home.

IMPORTANCE OF "BEATING THE MINER TO IT"

Mr. Moorshead spoke quite forcibly on the ability to deal with the miner as being even a larger element of success than technique. He said the trouble with most managers was that they let the miner form his conclusions without due consideration of all the facts of a proposition. When the miner had once made up his mind and passed his resolution in union meeting it took months of negotiation to change his attitude, whereas five minutes of protest prior to the meeting would be likely to have the desired effect. He advised the management to "beat the miner to his decisions" by foreseeing what the miner is going to do and putting in his word first. If the local has pronounced on the subject, months of parleying are likely to follow, as likely as not without result.

Joe Harris, a miner, brought to the congress by Mr. Adams, said that the miners were not altogether to blame. The powder frequently is badly graded, and the quickness of the shot and the force was hard to determine. Holes of too big a diameter frequently were drilled, and such holes were dangerous.

Adam Borton, another miner, complained also of the lack of uniformity in powder, making standardization difficult. He declared that no shotfirer should shoot a hole that is too deep or of too great a diameter. He said that when he made his rounds he found some of the holes only partly completed. How deep the men intended to make these holes he never knew. He could only tell them how deep they should be. With such holes there might well be trouble. Those that were completed could be measured and if found of right length could be charged and fired safely. James Creighton and other miners followed along similar lines.

At the Mine Transportation meeting, at which R. Dawson Hall acted as chairman, J. H. Edwards, electrical engineer, Elkhorn Piney Coal Mining Co., Huntington, W. Va., read a short discussion on the advantages of standardized track gages, especially having regard to the experience of his company. His written statement follows:

"The Elkhorn Piney Coal Mining Co., which has been operating six properties in southern West Virginia and eastern Kentucky, has found that the greatest obstacle encountered during its efforts toward standardization

of equipment has been the difficulty introduced by the different track gages. All except one of the six operations were acquired as producing mines and among those taken over were to be found the following track gages: 36, 40, 42, 44 and 48 in.

"An effort was made to eliminate from each operation any type of equipment of which only one or a few units were in use, and yet for which it was necessary to carry a full line of repair parts. Four types of mine locomotives were eliminated, resulting in a reduction of \$6,000 in the stock of locomotive repair parts normally kept on hand at the mines. Nine types of mining machines were discarded, resulting in a reduction of \$11,000 in the stock of that class of repair parts. Most of the standardization was effected by transferring equipment from one operation to another, but certain items, in most cases those which had become partly obsolete, were disposed of by sale.

"The standardization of locomotives, mining machines and other mechanical and electrical equipment made possible a reduction of more than \$45,000 in the stock of repair and spare parts carried. In addition to the above specific illustrations of gain by reductions in stock of spare parts kept on hand, it should be mentioned that still greater advantages of standardization were evident in a more economical operation of equipment owing to the fact that the machine operators, motormen, repairmen and foremen became much more proficient through the continual use or supervision of only one type of machine for each kind of job."

Mr. Edwards, on being asked, stated that the management had favored a 42-in. gage as standard. Frank Haas, consulting engineer, Consolidation Coal Co., Fairmont, W. Va., declared that they probably always would have more than one gage, as narrow gages were needed in mines having bad roof. However, the Consolidation Coal Co., which had inherited a 42-in. gage had at its new mines, switched over to 48 in. He said that with cars having a 42-in. gage the track should be $\frac{3}{4}$ in. wider where the curve is on a radius of $24\frac{1}{2}$ ft, and the wheelbase is 36 in. As regards bottom-dump cars, he believed that they could hardly be constructed safely in excess of $1\frac{1}{2}$ or 2 tons capacity.

VIRTUAL WHEELBASE LONGER THAN ACTUAL

Mr. Illsley, electrical engineer of the Bureau of Mines, said that the U. S. Bureau of Mines was making a careful study of the friction of mine cars in relation to track curvatures, wheel diameters, wheelbases and bearings. Mr. Hall called attention to the great length of the virtual wheelbase on curves due to the impingement of the flange on the rails and also referred to a statement by William Griffith, of Scranton, that the weight of the wheels had a greater effect in resisting traction than an equivalent weight in the body of the car. Mr. Hall said that Mr. Griffith had proved this to his own satisfaction and that figures on the resistance of railroad cars obtained by Mr. Griffith sustained him in that opinion. Mr. Griffith believed that the rolling parts of mine cars and railroad cars were being made too heavy.

On the question "When and Where to Use Gasoline, Trolley and Electric Storage-Battery Locomotives," J. H. Edwards advocated the more extended use of the combination locomotive, stating that when this was done and the trolley was extended as fast as new work was opened unusual grades could be negotiated satisfactorily by the storage-battery locomotive from one

end of the day to the other. Mr. Benedict stated that in discussing the grade on which storage-battery locomotives can be used the frequency with which such grades must be encountered must be considered. With many grades of 10 per cent the storage battery would soon be bereft of power.

When the subject "Roller Bearings vs. Plain Bearings" was broached W. L. Affelder, general manager, Hillman Coal & Coke Co., Pittsburgh, Pa., stated that though more care is needed to be taken of the wasteful use of power where generated at an isolated plant, operators were more prone to watch such waste when purchasing power. The purchase of power therefore had done much to make the introduction of roller bearings rapid. He stated that he fully believed that roller bearings justified their use by reason of the power saved.

POWER SAVING NOT THE ONLY ADVANTAGE

H. K. Porter, of the Hyatt Roller Bearing Co., declared that the roller bearing was not to be advocated solely as a power saver. It saved in keeping the cars on the track, in lessening replacements, in the lubrication of cars both as to labor and as to lubricant. If the roller bearing never saved a kilowatt of power it would be amply justified by its other qualities. Furthermore, with roller bearings on the locomotive and cars the tractive effort required of the storage-battery locomotive is so greatly reduced that a locomotive that would run only part of a day could have its service extended a full day and could work at more nearly its full capacity the day long—an important consideration, making it possible to avoid boosting the batteries.

In the discussion on the "Advantages and Limitations of the Caterpillar-Mounted Shovel" J. F. Joy, of the Joy Machine Co., said that unless a machine had a long reach or the track was set in the center of the room the caterpillar mounting was absolutely necessary. A machine having long reach was likely to tip and come off the track. Where the track is over 42 in. wide, wheels can be used. Under 42 in. the caterpillar truck was preferable. By leaving a thin layer of bottom coal the caterpillar could be made to work over even the softest of clays but that was rarely advisable. He said that with his machine, the load on the caterpillar per square inch did not exceed the weight which a man imposed per square inch on the soles of his shoes when standing. Only in exceptional places and under unusual conditions was the caterpillar likely to become bemired.

On Wednesday afternoon the forum opened with a discussion on "Underground Power Equipment and Transmission" with R. Dawson Hall as chairman, the particular subject discussed being as to the relative desirability of alternating current and direct current from the standpoint of efficiency and safety. The question was on its way to pretty general settlement when fortunately, or unfortunately according to the point of view, C. L. Harrod, of the Indiana Coal Operators' Association, came in and took up the cudgels for the use of alternating current for mining machines—the well-recognized point of view of the Middle West, the East holding pretty generally to the view that nothing is to be gained by mixing current. Before Mr. Harrod came in it was generally conceded that big pumps and pumps near a borehole to the surface could best be run by alternating current and that alternating current could be favorably used on the surface and for distribution to substations but on the whole the current

below ground for all services should be direct current.

F. C. Pullen of the General Electric Co., wanted to know how 3,000-kw. pumps like those at Ishpeming, Mich., could be economically run without alternating current. It was pointed out that they lie near the shaft and if they did not, such installations of large units are, and must always be, a law to themselves. Where electric power was used for hauling, however, smaller gathering pumps could get their power from the direct current installed mainly for other purposes.

LOW-VOLTAGE ALTERNATING CURRENT WASTEFUL

J. H. Edwards said that where direct and alternating current were distributed at the same voltage the losses with direct current were less than with alternating, for there was no inductance. Alternating current was best fitted for use where voltages were high, but with such high voltages the current could not be used for general mine purposes till it had been stepped down or converted to direct current.

Another member present, in discussing the possibilities or rather the near impossibility of using alternating current for haulage underground, stated that with direct current speed control was the more easily obtained. Starting torque, however, could be best obtained with alternating current. In considering the availability of alternating current, the space which machinery to handle it would require must be borne in mind. It must be remembered that it is essentially uneconomical as the power factor can never be 100.

Here Mr. Harrod came in, declaring that with alternating current, mining machines and pumps could be run in idle time when the locomotives were not running without the necessity of running converting equipment. He also said that in the Middle West machines cut during the day and not during the night, as in the East. Thus the machines and the locomotives were drawing on the power at the same time and two series of wirings were therefore more justifiable.

In discussing "The Relation of Feeder Lines to the Return Current" J. H. Edwards said that the feeder lines should be tested by the short-circuit test. After the return has been made perfect there is no reason to provide a feeder equal to that which the return will carry. That would be a waste of money if the power demanded by the machines and locomotives could be supplied without exceeding the prescribed voltage drop.

WHEREIN CENTRIFUGAL PUMPS EXCEL

In the session on "Pumps and Mine Drainage," also presided over by R. Dawson Hall, G. V. Woody, of the Allis-Chalmers Manufacturing Co., stationed at Wilkes-Barre, Pa., read a paper on the relative desirability of various kinds of pumps urging that centrifugal pumps handling 1,000 gallons per minute or more were more economical than plunger pumps of the same capacity because of lower first cost both for equipment and emplacement and because of lower repair costs. Centrifugal pumps though less efficient would be more economical. Furthermore they do not take such a large and expensive pump room as the plunger units and the amortization of, and interest on, that investment with reciprocating units is considerable. C. R. Smith, of the Layne Bowler Mine Pump Co., then described a deep-well pump for installation in a borehole.

All the sessions of the Open Forum on Thursday were under the chairmanship of J. C. Wilson, of the Ohio Brass Co. Dr. John H. Barr delivered an address on the

"History of Power Transmission" the outcome of careful investigation the world over into the early methods of transmitting power. These inquiries had been made by F. L. Morse and C. L. Saunders of the Morse Chain Co. The address was accompanied by several illustrations from wall paintings, book illustrations, sketches and even a stained-glass window.

J. H. Edwards desired to know what efficiency could be obtained with various kinds of drive. Mr. Wheeler said that with silent chains the efficiency lay between 97 and 99½ per cent and that with belt driving it was about 90 per cent when the belt was new and 10 to 15 per cent lower when the belt was old. He declared that a silent chain continued to give the same efficiency after a long period of use. These figures are for the chain and belt alone and not for the bearings, the resistance of the latter being an additional cause of power loss.

Mr. Day, of Falk Corporation, said that with best lubrication friction loss with herringbone gears was 0.25-0.5 per cent. With heavier lubrication the loss would be more, yet it might be advisable to provide such lubrication in actual practice. In the case of marine turbine gears the efficiency ran from 98.7 per cent down to 97.4 per cent. This included all losses both for the gears and the journals. The losses of power were approximately the same whatever the load; in consequence the proportion of losses fell as the ratio of load to full load increased.

Dr. Barr said that at Cornell it had been ascertained that with a silent-chain drive, the losses due to the friction of the chain and the journal friction were such as to give an efficiency of 98.7 per cent.

The Standardization Meeting held its fourth general session on Thursday under the chairmanship of Lucien Eaton, of the Cleveland-Cliffs Iron Co. W. A. Durgin, of the Division of Simplified Practice of the Department of Commerce, addressed the meeting, using lantern slides to illustrate his remarks. He said that the Committee on Waste of the Federated Engineering Societies had found that the industries investigated were only 49 per cent efficient. The engineers who made that report cut the inefficiency alleged from 51 to 40 per cent so as to be on the safe side. The Department of Commerce has decided that it will be safe in assuming that industry is at least 20 per cent inefficient.

With a production of \$50,000,000,000 of commodities per annum the loss must be \$10,000,000,000. Our tax bill is conceded to be crushing, but it totals only \$8,000,000,000. It could readily be met by savings in industry.

SIMPLIFYING BY ELIMINATION OF TYPES

Among the big losses is the great variety of articles made. Every manufacturer seems to pride himself on the variety of his line. He could just as well get out a few standard patterns and stick to these instead of evolving a new one every day.

What Mr. Hoover is trying to do is to hasten the process of standardization. He realizes that the word is not popular. No one wants to be standardized. The standardization movement has supplied the press with many striking subjects for jibes. Mr. Hoover proposes "simplification" instead of the older term. This word appears to be, and is, less scientific than standardization. Instead of inquiring definitely what is the best, he would immediately inquire what design sells best or at least is most sold and then make this the standard till inquiry experiment and discussion develop a better one. Mr. Durgin said that, for instance, the bowl seat for agri-

cultural implements and tractors was made in a multitude of forms, with slits and holes of various kinds and of many different shapes. Of all of them, however, one was most generally used, and the work of scientifically selecting the best was a job requiring much research as to the relation of the seat to anatomy, ventilation, to the difficulty of shaping and to many other matters. These problems were all answered by taking the seat most commonly used and adopting it at least as a temporary standard.

Albert W. Whitney, chairman of the Engineering Standards Committee, spoke on the necessity for standardization and pointed out that many variations in vegetable and animal life had been rudely blotted out by the processes of nature. The number of our fingers, our toes, our eyes, our nostrils and our teeth is standardized by the rude hand of evolution. He said all standardization did was to hasten the action which when it acted by evolution, as it did in business as in nature, was cruel and crude. Our needs were clear and we might as well recognize them early and satisfy them rather than wait and suffer in consequence.

Charles A. Mitke, chairman of the metal-mining branch of the Division of Standardization, who is recovering from typhoid fever at Long Beach, Cal., was not present but Colonel Warren R. Roberts, of the coal-mining branch, detailed the advances of standardization in every department of activity in America.

IS THE FIRE DOOR A MENACE?

At succeeding meetings of the conference several important reports were made and there was discussion in some of them. The most notable was on machine loaders, and this has been covered by *Coal Age* in the report of the main meeting. The matter of fire doors versus reversing fans was inadequately discussed but it was pointed out that most coal mines must be ventilated continuously or gas will accumulate. In a metal mine ventilation is not so necessary and may be suspended temporarily by the use of doors. In that case the use of fire doors shutting off a burning shaft would be helpful even with men in the mine, provided that a second shaft is available, which is not always true at metal mines. The dangers of doors was not considered, apparently because those present, except one or two, sided with Mr. Mitke in the belief that a fire door could be shut at any time and under any conditions without menace.

Coal Consumption by Utilities Heavy in August; Power Production Declines

Electric public-utility plants consumed 3,196,950 net tons of coal during August, according to a report just issued by the U. S. Geological Survey. This compares with 3,034,915 tons consumed during July, according to corrected returns.

Fuel oil consumed by public-utility plants in August totaled 1,233,584 barrels, compared with 1,174,562 barrels in July. The average daily production of electricity by public-utility power plants during August was 150,200,000 kw.-hr., which was a virtual return to the May and June rates, thus confirming the occurrence of the "July slump" for this year.

The average daily production of electricity for the first eight months of 1923 and the proportion produced by water power were as follows: January, 153,300,000 kw.-hr., 34 per cent; February, 154,400,000 kw.-hr., 33.9 per cent; March, 152,500,000 kw.-hr., 36.3 per cent; April, 149,100,000 kw.-hr., 39.9 per cent, and May, 150,100,000 kw.-hr., 41.3 per cent; June, 150,800,000 kw.-hr., 38.9 per cent; July, 146,400,000 kw.-hr., 36.6 per cent; August, 150,200,000 kw.-hr., 34.2 per cent.

Problems of Operating Men

Prevention of Mine Explosions An Unsolved Problem

Recurring Disasters Makes Problem of Prevention Most Important — Continued Study of Conditions May Reveal Causes as Yet Unknown

AGAIN, the daily press is burdened with accounts of recent mine explosions and other disasters. Reading of the great number of lives sacrificed and children left fatherless and reflecting on the frequency of such disasters, we cannot refrain from being appalled and discouraged by reason of our seeming impotency in respect to their prevention.

The most recent disaster, which occurred in the Kemmerer mine, in Wyoming, and in which 99 miners lost their lives, makes us wonder if these terrible happenings will ever cease and, if so, what will bring about their cessation. In the face of all that has been done to prevent such occurrences, it is not strange that we are discouraged by their continued recurrence.

Today, as a means for the protection of the lives of mine workers, we have a Federal Bureau of Mines and State Mining Departments with their staffs of inspectors and a great army of certified mine foremen and firebosses. Notwithstanding this, the question is uppermost in our minds as to whether miners, today, have any greater assurance of safety than they had a decade ago. This is not intended as a reflection on the work of these organizations, but merely to emphasize the meagerness of our knowledge of conditions that prevail and underlie the work of mining coal.

SEEMINGLY WE HAVE YET MUCH TO LEARN

Time after time writers in *Coal Age* have advanced practical suggestions in reference to reducing the number of explosions in mines. Safety rules have been formulated, but how far these are being followed by miners and mine officials it is impossible to say. All we know is that the danger is not removed and is as imminent today as at any period of the past.

The question comes home to all of us, Are there some things yet to be learned regarding the causes of explosions in mines? It is not so long ago that these were attributed exclusively to gas. Then, explosions occurred under conditions that made it plain that gas was not the sole cause. Evidence pointed to the presence of fine dust as being a factor responsible for the initiation and propagation of the destructive blast.

Investigation showed that some coal dust was inflammable to a greater degree than other dust and that the fineness of the dust was also a problem. It was discovered that, under favorable conditions, the presence of this fine dust was a menace to the safety of the mine and if subjected to a flame of sufficient intensity and volume there would result a disastrous explosion.

Just here, let me ask, if our investigations have stopped there? Besides gas and dust, are there no other causes or conditions that will make an explosion possible? In this connection, I can do no better than to quote from a former contribution I made to *Coal Age* in 1915, in discussing the question of "Preventing Mine Explosions." (Vol 8, p. 269.)

POSSIBLE FACTORS IN MINE EXPLOSIONS

At that time, I asked "How much do we know in regard to the effect of strong air currents and the greater or less amount of available oxygen in the mine air; and to what extent are these actual factors in the initiation of an explosion in a mine, as has often been suggested by (the late) John Verner, former mine inspector in Iowa? Again, do we thoroughly understand to what extent or in what way changes of temperature, barometric pressure and seismic disturbances create conditions favorable to explosions in the mine?"

Did we know and understand all the conditions and causes that initiate and propagate explosions in mines, we could then doubtless prescribe an effectual preventive. But, as long as conditions exist that are favorable to explosions and regarding which we know little or nothing, it will be difficult to reduce their number or safeguard our mines against such disasters.

That both gas and dust accumulated in mines will, under favorable conditions, be the means of producing a destructive explosion is well known today. We realize that these elements of themselves are harmless; but the danger lies in their coming in contact with a spark or flame of sufficient intensity to cause their ignition. Knowing this, we are forced to the conclusion that disasters in gassy and dusty mines can be eliminated, or at least reduced to a minimum by adequate ventilation and other preventive measures.

GREATER CARE NEEDED TO AVOID DISASTER

Precaution suggests safer methods of installing high-voltage electric wires in mines generating gas or dust. Such mines are not immune from danger when operated with open lights, however well they may be ventilated and safeguarded by efficient and vigilant mine officials. Sudden changes that are always possible, in roof conditions, may release a quantity of gas that would be extremely dangerous if the mine is not worked exclusively with safety lamps of an approved type.

In conclusion, let me say that, even if our knowledge of conditions and causes that invite explosions was complete and rules prescribed to make the mine safe, nothing would be accomplished unless the rules were strictly followed by every worker in the mine. The careless act of a single miner may cause the injury or death of many others, who become the innocent victims of his neglect or disregard for safety.

Forgetting that there are a large number of careless and indifferent men employed in mines, some of

whom think or care little about their own safety, I am inclined to think that we are too often ready to attach blame to mine officials when disasters occur. We must remember there are miners who are opposed to all rules and restrictions and who will violate them at the hazard of their own lives. No mine can be safe when such men are employed. The strict observance of rules by all employees is essential to safety and this is particularly true in mines generating gas and dust.

Dayton, Tenn.

JOHN ROSE,

Former District Mine Inspector.

Ventilating by Compressed Air

Accident caused by attempt to remove gas with compressed air—System unreliable as a means of ventilation—Fan required for efficiency.

AFTER reading carefully the various letters relating to the attempt of a fireboss to remove a body of gas, by means of compressed air, which have appeared in recent issues of *Coal Age*, I concluded there was much uncertainty in regard to the actual occurrence and the movements of the fireboss, who with the unfortunate pumpman lost his life as a result. The writer of the last letter on this subject, however, S. K. Mottishaw, *Coal Age*, Aug. 23, p. 289, I notice takes exactly the same stand as that taken in a previous letter, by John Rose. (Vol. 23, p. 978).

As remarked by Mr. Rose, if we take his assumption to be correct, "It was not only a most careless, but a highly foolish act for an experienced fireboss." With that conclusion I am in hearty accord. The blast from the high pressure air line striking the lamp, whether the latter was sitting on the floor or was carried by the fireboss, was certainly sufficient to force the lamp flame through the gauze and ignite the gas surrounding the lamp.

This incident is only one of many others that reveal the careless acts of some firebosses who, in spite of their experience and knowledge, persist in taking chances and doing things that they know are not warranted by the conditions about them. It does not always happen, however, that the one to blame pays the forfeit by the loss of his own life, as in this case.

NO RELIANCE ON AIR LINE FOR VENTILATION

Attention has already been drawn to the fact that the use of compressed air for the purpose of removing a body of gas is dangerous and should never be attempted. Where a mine is equipped for using compressed air for driving drills and coal cutters it is often the case that too much dependence is placed on tapping the air line for the purpose of ventilation. While the air exhausted by the machines is an unquestioned benefit and improves the ventilation of the place, no dependence should be placed on that as a means of ventilation.

It is well known that there are too many things to interrupt the continuous flow of the air from the pipes. The engine at the powerhouse is often stopped and started many times, during a twenty-four hour run. Again, there are numerous valves at different points on the pipe line and these are opened and closed, from time to time, which makes the system unreliable as a means of ventilation.

In closing, let me emphasize the point I wish to make that the sole dependence for efficient ventilation of a mine should be placed on the continuous operation of a suitable fan. While I do not wish to imply that the

use of safety lamps is not essential in mines generating gas, yet I consider that the operation of a good ventilating fan is even more important than the light question, in a gaseous mine. While I believe in the exclusive use of safety lamps in gas, my conviction is that the providing of good ventilation in all mines is of far greater importance.

R. W. LIGHTBURN.

Gans, Pa.

Improvement of Mining Law

Enforcement of existing laws more needful than making new ones—Status of mine foremen and firebosses—Responsibility under the law.

PERMIT me to endorse the reference made by F. C. Cornet in his letter, *Coal Age*, Aug. 9, p. 218, regarding the need of enforcing our present mining laws in making our mines safer for work. Mr. Cornet remarks, "Certainly it is not right to ask our legislators to make new laws for us so long as we fail to give a fair trial to those now on the statute books."

He advises caution in respect to making changes in present laws and the framing of new ones, claiming that too many or too stringent laws would hamper the industry without increasing the safety of mining. With him I believe that it is more important to enforce the laws we now have than to enact new laws that would probably prove no more effective in attaining the purpose sought.

POINT NEEDING REVISION IN PENNSYLVANIA LAW

In this respect I am speaking with reference to the Tennessee mining laws and the conditions that prevail in our own state. My knowledge of the mining laws in other states is not sufficient to permit me to judge regarding their need of revision, except it may be in a few particular instances that have come to my attention and which have a common bearing on the conditions of mining in all coal-producing states.

One such instance, which has been thoroughly discussed in the columns of *Coal Age*, illustrates the danger that may result from changing laws that have proved effectual in maintaining safe conditions in mines. I refer to that provision made in the Pennsylvania law that authorizes the mine operator to employ uncertified mine foremen and firebosses. It is not my intention to expand further on this point, however.

FEDERAL EMPLOYMENT OF FIREBOSSSES

Another question that was broadly discussed in *Coal Age*, not long since, had reference to the suggested employment of mine firebosses by the federal government, instead of by the operator or company whom they served. In this connection, let me say that, here in Tennessee, the duties of both mine foremen and firebosses are prescribed by the law, which holds them responsible for any negligence on their part although they are employed by the company operating the mine and not by the state.

Few will deny that the two most important and necessary qualifications of all firebosses are competency and honesty in respect to the performance of their duties. Possessing these qualifications, it goes without saying that they will make safe officials whether employed by a company or by the federal government. On the other hand, if a fireboss does not have these qualifications, he will prove an unsafe official and it matters not who employs him.

For my part, I have never been able to see how the

employment of firebosses, either by the state or the federal government, could make our mines safer than they are under the present system. One thing is certain, the scramble for state and federal appointments always involves the idea of patronage; and it is generally true that, the more incompetent an applicant for a position may be, the more he will rely on his political pull.

Since the man with the strongest pull is the one commonly chosen for the place, it is reasonable to conclude that the employment of firebosses by the state or federal government would mean the appointment of many incompetent men for this responsible position. In other words, the more incompetent and dishonest applicants would generally land the job and the lives of our miners would be endangered thereby.

Dayton, Tenn.

OBSERVER.

Dowthrow or Uptthrow, Which?

Hade of fault shows the fissure as having an inclination greater than that of the seam—Fault probably a dowthrow—Follow the lesser angle in the seam.

KINDLY permit me to refer to the inquiry that appeared in *Coal Age*, Vol. 23, p. 608, in which the inquirer stated that all efforts to find the coal beyond the fault had proved unavailing. If the hade of the fault line is rightly shown in the illustration given in the reply to this inquiry, I would say that the fault is undoubtedly a dowthrow.

By the "hade," I mean the angle that the fault line makes with the vertical. In this case, the fault line is shown as very steep and having an inclination greater than that of the seam. As stated in the reply made by the editor, I would follow the lesser angle in the seam, assuming the fault to be normal. As indi-

SEAM FAULTED ON A STEEP INCLINATION

cated in the accompanying figure, the lesser angle is at the floor and the fault, in my opinion, must be a dowthrow.

Some time ago, I remember, a writer, who discussed the question of finding the coal beyond a fault, stated that the deflection of the cleavage lines, in the seam at the fault, always pointed in the opposite direction from that in which the displacement had taken place. He said that if the deflection was upward the fault was a dowthrow; and, *vice versa*, if downward, the fault would be an uptthrow.

In spite of his claims that he has many times observed this to be the case, I want to say my experience is quite to the contrary, and I believe most mining men will agree that the bending downward or upward of the strata, in proximity to a fault, or any observed change in the inclination of the seam, is generally a fair index of the direction taken by the slip.

Inquiries Of General Interest

Weight and Percent of Screenings, Pittsburgh Run-of-Mine Coal

Specific Gravity and Weight of Coal Varies
—Average Weight of Prepared Run-of-Mine
Coal — Estimated Percentage of Screenings

HAVING in mind making certain changes in our tippie arrangements at the mine, I am particularly desirous of obtaining reliable information on two points in respect to No. 8 Pittsburgh Run-of-Mine coal of a highly volatile character. First, what is the average weight of this class of coal per cubic yard? Second, what average percentage of screenings may be expected to pass through the screen when the rods are spaced one inch apart, which is the arrangement I plan to make, believing it will be of advantage?

The data I have been collecting, for some time past, shows considerable variation and makes me anxious to learn facts that will be more reliable.

OPERATOR.

Akron, O.

At our request, A. F. Brosky, Pittsburgh editor of *Coal Age*, has given this matter close attention and sends the following information as being the most reliable:

The specific gravity of the coal forming the Pittsburgh seam, sometimes known as the "No. 8 seam," varies between the limits of 1.28 and 1.41. Taking the lower estimate, coal having a specific gravity of 1.28 will weigh, per cubic yard in the solid, $27(1.28 \times 62.5) = 2,160$ lb. Again, coal having a specific gravity of 1.41 will weigh, per cubic yard in the solid, $27(1.41 \times 62.5) = 2,380$ lb.

Observation and inquiry show that a fair average for this seam, in the Pittsburgh district and Ohio, may be taken as 1.31. This average specific gravity would make the weight of a cubic yard of the coal in the solid $27(1.31 \times 62.5) =$ say 2,210 lb.

Reports from various sources in the district show that the average weight of prepared run-of-mine coal (lump, nut and slack) of this class is about 1,300 lb. per cubic yard. We must bear in mind, however, that the particular character of the coal and the method of shooting, which vary in different localities where this seam is worked, will necessarily cause a considerable variation from this estimated average weight. Reliable figures, in any particular case, can only be reached by a careful consideration of both the hardness of the coal and the method of its extraction.

The foregoing remarks apply equally to the quantitative measure of screenings, in the handling of the coal in its preparation for the market. The character of the Pittsburgh seam and the hardness of the coal depend entirely on the location of the mine. Also, the manner in which the coal is mined will cause considerable variation in the relative proportions of lump, fine coal and slack.

A careful survey of the entire territory where this seam is mined justifies the statement that, under aver-

age conditions, from 35 to 40 per cent of the coal coming from the mine will pass through a 1-in. screen. Both the inclination and length of the screen bars, as well as the spacing of the bars apart, affect the percentage of screenings.

It is quite unusual to find the screen bars spaced one inch apart, the common custom being to use either $\frac{3}{4}$ -in. or $1\frac{1}{4}$ -in. spacing of the bars. Reports show that from 40 to 50 per cent of screenings pass through bars $1\frac{1}{4}$ in. apart; while from 25 to 35 per cent of screenings pass through bars $\frac{3}{4}$ in. apart. By interpolation, we estimate that bars 1 in. apart will produce from 35 to 40 per cent of screenings.

Examination Questions Answered

Examination, for Mine Foremen Olympia, Wash., Aug. 1, 1923

(Selected 1st-Class Questions)

QUESTION—*What are the regulations, in the state mine law, in regard to the inspection of a mine by the fireboss? What report is he required to make and what information should the report contain if gas is found?*

ANSWER—The state mining law of Washington (Sec. 33) requires the appointment of a fireboss, in every mine where inflammable gas has been found within a period of twelve months, or where spontaneous combustion occurs. The law further specifies that the fireboss so appointed shall inspect all working places within three hours of the time for commencing work, using for the purpose an approved safety lamp. The law also (Sec. 34) forbids workmen entering a mine where firebosses are employed, until the mine has been examined and reported safe for work.

Each fireboss (Sec. 115) must make a report of his examination on a bulletin board provided for that purpose at the entrance of the mine, indicating each place where gas is found and stating that all other places are clear of gas. This must be done before permitting the men to enter the mine. The fireboss must also immediately make a written report, in ink, in a book kept for that purpose in the mine office on the surface. His report must show the time of the inspection, the cause of any danger found and the steps taken for its removal. Where gas has been found, the report must state approximately the estimated amount. Every place where gas is found must be re-examined before men are permitted to enter for work. Removing gas by brushing, which is a common practice among many of the old miners, is forbidden by law.

QUESTION—*What are your views in regard to using mixed lights in a mine generating explosive gas?*

ANSWER—Where a mine is generating gas, in any section, in quantity requiring the use of safety lamps, no open lights should be used in any portion of the mine. In other words, the safest practice is to require the exclusive use of safety lamps or electric cap lamps. There is always danger in permitting the use of mixed lights in such mines.

QUESTION—*What does the mine law require in regard to electric locomotives operated by a trolley wire in a gaseous mine?*

ANSWER—The law (Sec. 155) forbids the use of electric locomotives operated by a trolley wire in any portion of a mine generating gas, except on the intake air.

QUESTION—*What is the maximum potential that can be used in a trolley system underground; and what does the law say in regard to trolley systems installed after passage of the law?*

ANSWER—The same section of the law (Sec. 155) limits the potential used in a trolley system underground, to medium voltage; provided, however, that all installations made after the passage of the Act and where the power is not taken from a station supplying power to a mine in operation previous to the Act, the potential is limited to low voltage.

QUESTION—*State the conditions under which mine explosions are most frequently produced. In what way do various kinds of coal dust influence the character of the explosion?*

ANSWER—Mine explosions are more common in mines generating considerable quantities of gas or dust and where adequate measures are not taken to prevent undue accumulations of these elements of danger. This includes all mines generating gas and deficient in ventilation; and all dusty mines where proper precautions are not taken to prevent the accumulation of fine dust and its suspension in the mine air. Strict rules and regulations must be enforced regulating the blasting of the coal, the kind of explosive used, amount of charge and manner of tamping and firing the shots to safeguard such mines against explosions.

The inflammability of the coal and the fineness of the dust are the chief factors that determine the danger and influence the character of the explosion, should one occur. Every possible means should be employed to prevent the accumulation and distribution of the dust and its suspension in the air where it becomes highly explosive.

QUESTION—*At mines that require the use of safety lamps, what type of lamp does the law require? What regulations does the mine law require where safety lamps are used?*

ANSWER—The mine law of Washington (Sec. 131) forbids the use of any lamp other than a magnetic-locked safety lamp, or an electric lamp, except by superintendents, shotlighters or other certified men, who may use such lamps as are approved by the mine inspector of the district.

The same section requires that all lamps used shall be the property of the owner of the mine. Every lamp must be examined by a competent person appointed for that purpose, immediately before the lamp is taken into the mine. No lamp may be used until so examined and found to be safe, clean and securely locked. The law forbids (Sec. 132) the use of open lights in any section of a mine requiring the use of safety lamps; and (Sec. 133) makes it a misdemeanor, punishable by a fine of not less than \$50 or more than \$200, or imprisonment for a term of not more than one year, if any unauthorized person is found opening or tampering with a safety lamp or having matches or other lighting device. The law provides, however, (Sec. 135) that an operator may appeal from the decision of a mine inspector to place a mine on safety lamps when he considers such order unreasonable, the appeal to be made to the mining board and their decision to be final.

Coal Commission Report on Labor Turnover In Bituminous Coal Fields Shows

Industry's Turnover as a Whole Not Unusually High Though Excessive in Some Districts

Labor Most Unstable in Non-Union Fields—Replacement Lower
Among Machine Miners Than Among Pick Miners and Loaders—
Movement of Outside Day Men Exceeds That of Inside Day Men

The study of Labor Turnover in the Bituminous Coal Mines of the Country for 1921 shows all varieties and extremes when looked at mine by mine and district by district. The study has shown percentages ranging from 7 per cent in a sizable mine in northern Ohio to 459 per cent for another in northeastern Kentucky. It has shown contracts for districts ranging from 30 per cent for Michigan to 224 per cent for the Kenova-Thacker region of West Virginia. For the country as a whole the degree of turnover for the industry does not appear to be greater than that which is accepted as the common experience of industries generally. The result for the 691 mines studied for the year 1921 are as follows: Total average on rolls, 122,048; all separations from rolls, 121,840; turnover percentage, 99.9.

As was pointed out in the report on turnover in the anthracite industry this does not differ greatly, and in fact is less than the experience of industrial concerns during 1913-14 and 1917-18. Brissenden and Frankel* in their study of turnover in some 160 varying concerns found an average for 1913-14 of 115 per cent. For 1917-18, a war-time year, the turnover average they found was 180 per cent. Their tables show that it was uniformly the experience for larger employers to have the lesser rate of turnover. For concerns employing under 1,000, which are more comparable in size to coal mines, the 1913-14 average for 29 concerns was 146 per cent and the 1917-18 average for 67 concerns, 221 per cent.

The anthracite report also gave the turnover percentages from a 1921 study of 11 industrial establishments in Philadelphia, made by the Industrial Research Department of the Wharton School of the University of Pennsylvania. The turnover percentages for these were as follows: 22, 36, 41, 59, 64, 110, 66, 140, 145 and 183.

The general experience of the bituminous industry in 1921 does not differ greatly from that of the anthracite industry during the same year. The median percentages for the three anthracite districts were as follows: Lehigh, 55; Schuylkill, 115; Wyoming, 100. The average for the three districts would not be far from the 1921 figures for the bituminous industry since Lehigh, though it has the least turnover, is much the smallest of the anthracite districts.

TURNOVER OF LESS THAN 50 PER CENT SATISFACTORY

However, most progressive industrial establishments giving attention to the costs of labor turnover are not content with seeing a 100-per cent per annum figure. A certain amount of labor turnover undoubtedly is healthful to an organization, but it would seem that there is somewhere, though unestablished, a point of stability that lends to the greatest productiveness. Concerns maintaining a turnover percentage less than 50 per cent consider that a most satisfactory figure.

Table I shows the labor turnover in each of the 33 bituminous coal districts. This table and the accompanying diagram give a graphic picture of the variance in turnover percentages for districts. They show an astonishing contrast in the percentages for districts recognizably union and non-union. The non-union districts are uniformly much higher in turnover percentages than the unionized districts.

For purposes of reference the following lists of the dominantly union, dominantly non-union and equally mixed or balanced districts are given. These were the conditions as of the year 1921, at least so far as the mine representation in the tables of this study show.

Non-Union	Mixed	Union
Somerset (Pa.).....	New River-Winding...	Central Pennsylvania
Westmoreland, (Pa.).....	Gulf (W. Va.)	N. W. Pennsylvania
Connellsville (Pa.).....	Tennessee....	Panhandle-Fairmont (W. Va.)
Cumberland-Piedmont (Md.).....		Kanawha-Coal River (W. Va.)
Logan (W. Va.).....		Northern Ohio
Kenova-Thacker (W. Va.).....		Southern Ohio
Pocahontas-Tug River (W. Va.).....		Indiana
Virginia.....		Michigan
Northeastern Kentucky.....		Illinois—Danville
So. Appalachian (Ky.).....		Illinois—Central
Alabama-Georgia.....		Illinois—Belleville
Utah-New Mexico.....		Illinois—Southern
Colorado.....		Western Kentucky
		Iowa
		Kansas, Missouri
		Oklahoma, Arkansas, Texas
		Montana, Wyoming
		Washington

The graphic contrast which the chart shows on the union and non-union districts is subject to a variety of explanation. It would appear on the face of it that the non-union districts undergo an alarming instability. The causes probably are many. In the first place it seems reasonable to presume that unionized districts lend security of jobs to miners. That is, discharge is most uncommon in unionized mines, because of involved union protection.

The opinion of some non-union operators is that the men move quickly if work becomes slack and there is the faintest rumor of work elsewhere. The shifting rates of pay, from mine to mine, probably induce some of this movement among workers, seeking the best rate or the best working advantages. In any event, such high rates of turnover as exist in some of the non-union districts are certainly unhealthy from a managerial point of view. If organiza-

COMPARISON OF LABOR TURNOVER PERCENTAGES IN 33
BITUMINOUS COAL-MINING DISTRICTS IN 1921

*"Labor Turnover in Industry," (MacMillan, 1922.)

TABLE I—COMPARISON OF SEPARATIONS, ACCESSIONS, AND STABLE WORK FORCE FOR 33 BITUMINOUS DISTRICTS IN 1921

District	No. of Mines	Average		All		Total		Stable	
		No. on the Roll	Per Cent	No. on the Roll	Per Cent	No. on the Roll	Per Cent	No. on the Roll	Per Cent
1 Central Pennsylvania	50	11,431	9,408	82	10,808	95	6,638	58	
5 Northwestern Penna.	40	8,612	6,429	75	8,503	99	4,784	56

27 Iowa	31	5,614	4,279	76	4,498	80	3,232	58	
18 Michigan	6	874	265	30	268	31	719	82	
29 Oklahoma, Arkansas, Texas	12	1,665	826	50	1,036	62	1,098	66	
14 Kansas-Missouri	28	2,378	2,072	87	1,769	74	1,361	57	
32 Colorado	42	6,178	7,746	125	7,816	126	2,773	45	
30 Montana-Wyoming	22	3,804	3,998	105	4,421	116	1,981	52	
31 Utah-New Mexico	14	2,330	3,221	138	3,044	131	955	41	
23 Washington	6	993	504	51	696	70	652	66	

tion morale, familiarity with the establishment, and settled community make-up have any value, the waste is certainly high in such districts as Logan, where but 25 per cent of the mine work force is stable or steady throughout the year, and the turnover runs up to 230 per cent per annum.

The mixed union-non-union districts of Tennessee and New River-Winding Gulf (W. Va.) present a peculiar contrast to the extremes of the union and non-union districts. The turnover percentage in Tennessee is shown as 122, and that of New River-Winding Gulf, 148. One non-union district has a lesser percentage than Tennessee and four less than New River-Winding Gulf. No union districts have higher percentages than these two. Within the districts, however, there do not appear to be any marked differences in the experience of non-union and union mines.

Comparison of the percentage of stable or steady workers in the various districts, of course, bears a definite relationship to the turnover. As turnover increases, stable workers customarily decrease. It is therefore true that the union districts are more stable than the non-union. The actual range of stability is from 19 per cent for workers in the Kenova-Thacker district in West Virginia to 82 per cent for Michigan. The case of Michigan's unusual stability could perhaps be explained by the possibility that there is no competitive field of industry which would tempt these workers. In other words, it may be that there is no place for them to go if they decide to leave these mines.

The range of stability in the recognizable non-union districts is from 19 per cent for Kenova-Thacker to 60 per cent for Westmoreland in Pennsylvania. The range of stability for the union districts is from 50 per cent for Fairmont (W. Va.) to 82 per cent for Michigan.

Some comment should be made on the Westmoreland district because it stands out among the non-union areas with a high degree of stability among workers and a comparatively low rate of turnover. Westmoreland has a turnover percentage of 81, as contrasted with the 121 per cent for Somerset and 152 per cent for Connellsville, the other two non-union Pennsylvania districts. Its percentage of stable workers is 60, as compared to 48 per cent for Somerset and 42 per cent for Connellsville. There is nothing in the Commission's data to particularly account for this contrast.

The study has shown some contrasts in the turnover

among the occupational groups. For the 691 mines covered the percentages of turnover for the five occupational groups are as follows:

	Average No. on Rolls	Total Separations	Turnover Per Cent
Machine miners	5,171	3,916	75.7
Pick miners	30,807	29,763	96.6
Loaders	39,891	43,825	109.8
Inside day men	30,874	28,534	92.4
Outside day men	14,646	15,032	102.6

The lowness of the figure for the machine miners may be explained by the fact that this is preferred work and that earnings probably are better in this group. The loaders perhaps have the hardest task in mining, and this would explain in a degree the higher rate in this group. Some surprise may be occasioned by the fact that the turnover is greater among outside day men than among inside day men. It has been something of a popular belief that men preferred to work above ground. This 10 point difference is not explainable from data available. It is of interest to note that the median percentage of stability in the 33 districts is 59 for inside day men and 65 for outside day men.

Table II shows the turnover percentages on the occupational groups in each district. It bears out in a degree what is noted as particularly true of occupational groups in tables 1-66 [accompanying the report] for individual mines in districts, i.e., that where the turnover is high in one group, it is as a rule, uniformly high in the others.

TABLE II—PERCENTAGE COMPARISON OF LABOR TURNOVER BY OCCUPATIONAL GROUPS IN 33 BITUMINOUS DISTRICTS, 1921

District	Pick Miners	Machine Miners	Loaders	Inside Day Men	Outside Day Men
Central Pennsylvania	108	59	86	57	74
Northwestern Pennsylvania	78	52	87	54	61
Somerset (Pa.)	124	104	152	96	97
Westmoreland (Pa.)	80	49	105	61	78
Connellsville (Pa.)	168	152	201	111	137
Cumberland-Piedmont (Md.)	79	...	111	61	89
So. Appalachian (Ky.)	294	124	229	179	206
Northeastern Kentucky	280	97	226	203	199
Western Kentucky	101	35	52	68	56
Tennessee	116	163	176	67	116
Alabama-Georgia	75	51	76	82	97
Virginia	157	122	198	177	279
Logan (W. Va.)	295	209	213	232	271
Kenova-Thacker (W. Va.)	300	270	220	249	221
Kanawha-Coal River (W. Va.)	140	86	190	156	136
Pocahontas-Tug River (W. Va.)	137	190	233	192	175
Winding Gulf-New River (W. Va.)	234	150	134	154	138
Fairmont (W. Va.)	108	98	116	86	98
Northern Ohio	33	46	73	65	64
Southern Ohio	...	48	90	62	49
Indiana	53	50	55	76	100
Illinois—Danville	64	36	33	41	44
Illinois—Central	68	35	61	76	49
Illinois—Belleville	68	48	69	82	40
Illinois—Southern	60	59	73	53	28
Iowa	79	92	76	71	76
Michigan	11	22	28	36	37
Oklahoma, Arkansas, Texas	51	94	62	38	49
Kansas-Missouri	97	40	98	64	66
Colorado	129	123	163	87	122
Montana-Wyoming	131	57	100	87	88
Utah-New Mexico	163	61	143	123	110
Washington	51	0	50	41	59

It should be understood that the tables and data presented herein have been subjected only to a limited analysis and interpretation to meet the broader purposes of the Commission. The study has shown chiefly these things:

(1) That the turnover for the industry as a whole is not remarkably high, as compared with other industries, although it is excessive in some districts.

(2) That for various reasons labor is much more unstable in non-union districts than union districts.

(3) That in mixed non-union and union districts the turnover percentage occupies a middle point between the extremes of the other two.

(4) That the turnover among machine miners is noticeably lower than that for the other two tonnage worker groups, pick miners and loaders.

(5) That the turnover is higher among outside day men than among inside day men, although the stability is greater in the first group.

Basix for Bituminous Study.—In undertaking the study of labor turnover in the coal industry, the desirability of making a current survey in the field was immediately considered. This would of course have permitted a checking

of the number of men having employment in mines and permitted some opportunities for ascertaining reasons for leaving and thereby the relative cause of turnover. But considering the extent of the industry and the vast number of mines, a field study was believed impracticable. The expense involved and the seeming absence of any administrative machinery in the mines themselves to do or assist in such work, put this out of consideration.

It was therefore determined that the study be made from that data which the Commission had available in the form of earnings reports on miners for the year 1921. This data consisted of schedules submitted by individual mines, showing by pay periods the earnings, days worked, etc., for each miner on a payroll during the year. It amounted to a draft of mine payroll for that year. The schedule used was known as Form L1. It possessed information sufficient to show separations from employment, complete separations or disappearances for the year, re-employments, and new hirings. It also, by a count of the full-year service men, furnished the number of the stable force, and likewise the number of men who were unstable. In addition it permitted a tabulation of the new men hired after the beginning of the year, and a tracing of the service of these men furnished the number of new hires who remained steadily at work until the end of the year.

Having these primary totals for computing turnover and its allied personnel data, the next question arising was what figure should be used as a basis for arriving at the turnover percentage.

BASIS FOR ARRIVING AT TURNOVER PERCENTAGES

The average number in attendance, a number obtained by taking the total man days worked and dividing it by the number mine days worked, was considered and a fairly accurate figure could be obtained for tonnage workers, i.e., pick miners, machine miners and loaders. But the outside and inside day workers had overtime lumped with regular time so that no accurate figure could be obtained. The reports showed many day workers as employed more days than the mine worked within a period.

It was finally decided that the average number on the roll for all pay periods worked would be employed. This figure was obtained by taking the total number of "man-pay" periods worked and dividing it by the number of pay periods the mine worked. This method took care of the men who worked a short time and gave full weight to the full-year workers.

The final question was the decision on what should constitute a "separation" or exit, the determining factor in computing the amount of turnover. Because of the irregularity of the industry and the fact that the schedules showed the movement of men largely in the time unit of the pay period it was decided that a disappearance of a man's name from the payroll (schedule) for one month (two consecutive pay periods) or more would constitute a separation. In addition this was a liberal interpretation likely to correct any errors of judgment on a lesser time allowance.

Thus, having defined the terms there were a few other questions which required answer. One was that regarding mines which worked only a part of the year. The conclusion here was that wherever a mine suspended operation for one or more pay periods (two weeks or longer) those idle periods would be disregarded. For example, employees who reappeared after a shutdown were considered as having been steadily employed. If they did not reappear they were counted as exits or separations. In this connection it was determined that mines operating less than 10 pay periods would not be considered in the tabulation. There was not a great amount of rejections on this account.

It was questionable whether the turnover might not be seriously affected in those mines where frequent suspensions or shutdowns occurred, or where few pay periods were worked. As the study developed it was found that with the two-pay-period separation as a basis for turnover little or no difference was noted between mines in one district working many pay periods and those in another working but few.

The actual tabulation became fairly simple after a code of checks was perfected and clerks' errors were detected

easily, owing to the form of the tabulation record. For example, there could not be more unstable men than separations, or more "new men hired on the roll Dec. 31" than there were total "new men hired." The re-employments added to the complete separations or disappearances gave the total number of separations or exits, etc.

It is the prevalent custom both in bituminous and anthracite mines to pay miners semi-monthly. Here and there occasional mines pay monthly and some pay bi-weekly as differentiated from the semi-monthly practice. But these differences did not prevent uniform interpretation of "separations."

The method of districting the bituminous coal areas was arrived at by taking a simple consolidation of a geologic and trade districting developed by the U. S. Geological Survey. It is felt that the districts are easily identifiable for the purposes of this report.

It was the original desire to secure at least a 50 per cent representation of the mines in each district. This was possible for some districts, but for others, which were uniformly late in submitting their schedules to the commission, this delay and the pressure of time prevented a greater representation. This means that in some sections in West Virginia, such as Logan and Kenova-Thacker, and the eastern section of Kentucky a more adequate representation is to be desired. Actually the study has covered approximately one-fourth of the first-rate mines in the bituminous industry.

This study was made possible in its extensiveness through the use of data which Miss Anne Bezanson collected primarily for the purpose of the study of earnings, which lent itself to the needs of a turnover study, which has been made by Delos Walker. The plan and method of the turnover study was mainly due to the interest and attention which Dr. J. H. Willits and Miss Bezanson gave to it at its inception and during the course of its development. The actual work of tabulation and compilation was immediately in charge of Miss Elizabeth B. Lundy.

Brydon Committee Reaffirms Labor Policy; Recommends Advisory Board to Wadleigh

In recognition of the valuable services rendered the coal industry by the Bituminous Operators' Special Committee, its entire personnel has been included in a sub-committee of what has been the policy committee of the National Coal Association. The policy committee, however, will drop that name and will assume that of the Bituminous Operators' Special Committee. In this reorganized form, the committee, at its meeting held Oct. 9 in New York, adopted a resolution which reads as follows:

"Resolved, that this committee fully endorses and reaffirms the principles laid down by the Bituminous Operators' Special Committee in its statement on labor relations made to the U. S. Coal Commission under date of Nov. 10, 1922. The members of this committee believe such difficulties as exist in the coal industry to be due primarily to the following elements:

"(1) The monopolistic control of mine labor by absentee union officials.

"(2) Nation-wide as well as local strikes brought about by an irresponsible and autocratic organization.

"(3) Appeals by agitators and propaganda designed to breed dissatisfaction and create unrest among the people at large.

"We believe further that the following basic principles cannot be ignored:

"That every man has a right to work without interference or compulsion; when, for whom and upon such terms as he may see fit.

"That, while the right of workers to organize for legitimate purposes cannot be denied, such organizations have no right to impede or restrain those who do not care to join or to deal with them.

"That the right of private property is, and must remain, inviolable.

"That, in the last resolve, the law of supply and demand always will determine prices; that no legislation long can interfere with this inexorable rule; that any interference can be justified only, if at all, in time of war and that at any other time such interference inevitably will produce greater evils than those which it seeks to suppress.

"Be it further resolved that the National Coal Association, and its officers as such, refrain from taking any part, directly or indirectly, in the negotiation of a wage scale, in general or by districts, in any of the union or non-union bituminous-coal fields of the United States.

"Resolved, further, that all the data and statistics now in the possession of the National Coal Association, as a result of the work of the Bituminous Operators' Special Committee, compiled and in process of compilation, shall be placed at the disposal of every bituminous operator or group of bituminous operators in the United States, except information furnished with the understanding that it is to be held confidential."

Before the foregoing action was taken, J. C. Brydon addressed the committee. Among other things, he said:

"My experience as chairman of the Bituminous Operators' Special Committee naturally and necessarily placed me in touch with many coal operators. I found some who thought the National Coal Association could not continue to function without definitely recognizing the major problem of the industry, the problem of labor. Their minds were not clear as to how the problem should be taken up or as to the action which should be taken with respect to it. There was no crystallized thought on the subject. On the other hand, there are operators who feel that the National Coal Association should have nothing to do with labor matters.

"In my opinion, labor is the major problem, but there are legislative problems and many other important matters with which to deal. It was to meet such a situation that this committee was created to secure the common judgment of the industry. Its membership includes operators within and without the National Coal Association. Its membership is divided evenly as between so-called union and non-union operators. Its members are so located geographically as to be representative of the country's production.

"This committee will not, and cannot, usurp the functions of the board of directors of the National Coal Association. I am sure I bespeak the thought of the membership of that association when I say that this committee can be very helpful. There will be times when matters of policy that affect the entire industry must be considered. At other times, only sections of the industry will be affected, but in either event the counsel and advice of this committee will be representative of the entire industry.

"It was helpful many times that the Bituminous Operators' Special Committee had a broader sphere of action than did the National Coal Association. I can foresee that such may be the case with the new committee.

"The Special Committee leaves a legacy of information and statistics gathered from every bituminous field in the country. Never before was such an array of facts and figures available to those who must make the industry's case. This information in the form of final compilations which are being made will be available to any operator or group of operators, excepting of course the confidential information which was entrusted to the committee."

A committee composed of the presidents of the National Coal Association, the American Wholesale Coal Association and the National Retail Coal Dealers' Association was recommended to F. R. Wadleigh by the Bituminous Operators' Special Committee in response to his request for a suggestion as to what sort of advisory committee should be created to co-operate with the Department of Commerce on coal matters.

JOHN L. LEWIS, president of the United Mine Workers of America, has accepted the presidency of a co-operative labor bank which will open in Indianapolis about Jan. 1, with a capitalization of almost \$1,000,000. Election of officers of the bank, to be known as the United Labor Bank & Trust Co., is to take place at the end of this month. A number of other unions, as well as that of the miners, are participating in the formation of the bank, it is announced.

THE U. S. SUPREME COURT on Oct. 10 issued a rule upon the Corona Coal Co. to show cause why the appeal in its case against the United States should not be dismissed. The case involves the basis of settlement for coal requisitioned by the Railroad Administration.

Iron and Steel Electrical Engineers' Meeting And Exhibition Well Attended

The annual convention of the Association of Iron and Steel Electrical Engineers at Buffalo, N. Y., Sept. 24-28, was the most successful in the history of the organization. This year the convention was held jointly with an exposition by more than a hundred manufacturers of electrical and mechanical machinery. Much of this equipment covered electric transmission, power drives, material handling and transporting machinery, pumping, control apparatus, power-plant accessories, together with steel-mill production apparatus. Many of these exhibits included operation and demonstration of the equipment.

The attendance, as reported by the association secretary, John F. Kelly, showed about 1,200 members present, a large proportion of the membership, which includes many coal-mining men who found both the exhibit and convention of great interest and value.

At the first day's session Walter C. Kennedy made an interesting survey of the rapid increase in the application of electric equipment. The saving in cost of attendance, maintenance and repairs in many instances has done much to further the application of electric equipment in the steel mill as also in coal mining.

The discussion on the work of the special bearing committee showed that there is an increasing desire on the part of those who have used ball- and roller-bearing motors to work out their problems with the manufacturers with a view toward standardizing on a range of fifteen different sizes of bearings for motors up to 100 hp.

The paper on "Motor Operated Centrifugal Pumps" brought out considerable discussion on the subject of overloading the motor when the pump operates at heads less than that for which the pump was originally intended. By using a 40-deg. rated motor it was shown that damage to the motor was more remote at low heads than when the pump was driven by a 50-deg. rated motor.

In the paper on "Economical Use of Fuel" H. C. Siebert gave examples showing that the average boiler plant operated at an efficiency of 50 per cent whereas it should be 80 per cent by the use of more efficient boilers and regulation and control of the fuel used.

The paper on "Tempering of Coal," by Thomas A. Marsh, gave results obtained by moistening coal before burning. The advantages claimed were: Less holes in the fire bed, higher combustion rates, less ash and less excess air. Interesting conclusions gathered from questionnaires, however, showed that although moistening coal is in general desirable it should be done only after careful study, as too much moisture or moisture added in stoker hoppers does not bring about the desired results.

"High-Pressure Steam Boilers" was the title of a paper by Dr. D. S. Jacobus, in which he showed how the superheating of steam was controlled by placing the reheater above the upper deck of boiler tubes and provided with a damper.

Thursday evening a banquet and dance was held at the new Hotel Statler. After the banquet announcement was made of the following officers for the coming year: President, R. S. Shoemaker, superintendent of maintenance, American Rolling Mills Co., Middletown, Ohio; Secretary, John F. Kelley, Pittsburgh, Pa.; Treasurer, James Farrington, Steubenville, Ohio.

Owing to the broadening of the field of the society, a suggestion has been made to change the name of the society to Iron and Steel Engineers. Action on this question will no doubt be given consideration at future meetings of the society and its branches.

THE INTERSTATE COMMERCE COMMISSION will continue its investigation of anthracite rates at hearings at Augusta, Me., Oct. 29; Montpelier, Vt., Oct. 31; Boston, Nov. 2; Albany, Nov. 5; Rochester, Nov. 7; New York City Nov. 9, and Philadelphia, Nov. 13. The commission's inquiry has been undertaken at the recommendation of the U. S. Coal Commission. A preliminary hearing was held last month at Pittsburgh.

Sees Non-Union Producers in Commanding Position as Result of Rigid Wage Agreement in Union Fields

Closing of Lake Season on Heels of Resumption of Anthracite Mining Expected to Be Depressing Factors to Organized Mines—Union Operators Unlikely to Be Able to Grant Increase or Fight Union

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Never before in the history of coal mining in America have the non-union coal operators been in as strong position as they are today. Even with the large number of non-union mines that have been opened during and since the war period, the depression which is slowly and surely settling around the coal business is bringing no gloom to the non-union territory. The operators there are buoyant because the next six months promise to be a succession of great field days for them. The union fields are tied, hand and foot, with an inflexible wage agreement. The Lake movement will be over soon, robbing portions of the union territory of much of the vitality that it still possesses. It now is apparent that the demand for bituminous coal to take care of the requirements of those who are unable to get anthracite will be small indeed. In fact the saturation point in anthracite will have been reached before many weeks have passed. Bituminous coal stocks are heavy—ten million tons more than those on hand during the corresponding period before the 1922 strike.

In the face of a situation such as they now are facing, the union operators have reason to feel gloomy. By the end of this coal year they will be in no position to grant an increase of wages. Neither will they be in a position to fight the United Mine Workers. They will be, more or less, at the mercy of that organization unless Congress should threaten some drastic action which would be indicative of crystallization of public sentiment against the forcing of the wage for one craft to the point where it loses all semblance of proportion with the wage paid in other industries for comparable service.

STRIKES ACT AS DOPE TO UNION MINES

Were the United Mine Workers willing to leave the whole matter in the capable hands of John L. Lewis, it is probable that he would give prompt assurance that no increase in wage would be asked for the workers in union bituminous mines. He knows that nothing would work more discomfiture to the non-union operators. He knows that if he takes full advantage of the weakness of the operators in the union fields and exacts the last shekel he can wring from them, it simply will close down an additional large number of union mines and throw another big block of tonnage into the lap of the non-union operators.

The growing schism between union and non-union operators is becoming more and more apparent. It is the outstanding weakness of the bituminous-coal industry. The operators were quite right in their New York meeting last week in reaffirming their statement that shortages and high prices of coal hark back to strikes, but it was these very strikes which brought prosperity to the non-union fields and put them in their present commanding position. These strikes have been as dope to the union operations. Following a strike, they have a period of hectic activity, but as the effect of the narcotic, in each recurring instance, wears off, the industry becomes more and more devitalized and unstrung. This is having its effect on the United Mine Workers. If the radicals and the one-eyed among them insist on pushing costs to a new high level, there are not going to be many mines left to check off.

The operators are correct in saying that the Harding Coal Commission emerged from its studies without recommending any national labor policy. We are no nearer an answer to the question as to whether or not we are to continue to have nation-wide strikes. It is significant, how-

ever, that the Bituminous Operators' Special Committee, in its old form or in its new form, has been just as inconclusive as was the Coal Commission. Its members can agree upon a denunciation in round terms of the monopolistic United Mine Workers, but they have no plan that promises any relief from present conditions. They can get together and affirm certain general principles, such as the right to work, the right to organize for peaceful purposes or to declare that private property should be inviolate, but their criticism of the civil liberties report applies with equal force to their own accomplishments. They can agree on a statement of abstract rights, but they cannot apply them.

The clash of interest between union and non-union operators is just as real, just as clear as it was in 1922. Apparently the application of any constructive principle must await the time when the non-union operators will pledge themselves jointly to maintain some reasonable, proper and constant relationship between their wage rates and those in effect in the union fields. If the non-union operators were to visit England and visualize the working of the district autonomy wage rate, they might see some advantages for the nation and even for themselves in the stabilization of rates.

I. C. C. Grants Rehearing in Assigned-Car Case; Change in Decision Unlikely

While the Interstate Commerce Commission has bowed to the large number of requests for a rehearing in the assigned-car case, there is no reason to think that the Commission will change its opinion as to the preferential use of cars for railroad fuel. The rehearing will be before Commissioner Aitchison at Washington, Oct. 22. The only hope of the protestants apparently is that some amendment may be worked out which will mitigate somewhat the blow to those owning private cars. There is a powerful influence behind the movement, in that this action is certain to be the forerunner of restrictions on private cars used for the transportation of commodities other than coal.

All admit that the decision has precipitated a serious situation for the owners of private coal cars. The number of coal cars privately owned is not less than 30,000, representing an investment of \$75,000,000. If the order of the Commission becomes effective, the owners of this property will have only one buyer. The cars will have to be sold to the railroads and they will take them at their own price, it is argued. In the case of some producers of coal, their investment in cars is greater than their investment in mines.

In certain instances, perhaps in many, prospective purchasers of private cars wrote to the Commission asking if there were any thought of abolishing their use. On assurances of the country, millions of dollars are thought to have been invested. It is known that this phase of the question will be emphasized at the rehearing.

The Commission's opinion, as it now stands, will result in great advantage to certain large coal-mining interests, it will be argued. Where the mines of a powerful company are served by a short railroad line, it will be possible for that railroad to purchase a large supply of cars which would assure those mines a full car supply. An instance is the recent sale of the Sandy Valley & Elkhorn R.R. by the Baltimore & Ohio to the Consolidation Coal Co., which owns

most of the mines on the line. This railroad already has a large ownership of cars. If the decision stands, there will be many cases in which branch lines will be sold in such a manner.

The private-car owners will argue that the Commission should not go further than denying them preferential use of railroad facilities for their cars. The validity of an order which goes beyond what is necessary to eliminate an actual discrimination will be questioned.

The long and respectable history of private cars will be reviewed. When the charter was granted to the Pennsylvania Company, the railroad was regarded as a public highway on which the user was expected to furnish his own vehicle for the handling of his freight. It will be pointed out that private cars have had a great effect on stabilizing the coal market and have been a great public safeguard, especially in their use by public-utility companies.

The attitude of those who favored abolition of the assigned-car practice toward the rehearing granted by the Interstate Commerce Commission is one of waiting for developments. A conference was held Oct. 15 by officials of the National Coal Association, which had advocated abolition of assigned cars for railroad fuel and which maintained a neutral attitude toward privately-owned cars, and arrangements were made for representation at the hearing. Inasmuch as the Coal Association is a party to the proceedings, traffic officials of that organization declined to comment upon the action of the Commission in reopening the case.

It was pointed out by some of those who had viewed with satisfaction the order of the Commission last spring doing away with the assigned-car rule that inasmuch as the Commission had this case before it about two years and took testimony and evidence for more than 30 days, the granting of only twelve days' time between the order for rehearing and the date of that rehearing indicates that the Commission expects argument and not further evidence to be developed.

Within the twelve days, it was declared, it would be practically impossible to obtain new evidence bearing on the case, even if all the evidence had not been exhausted previously. Supporters of the original decision assert that the move at the rehearing is up to the petitioners, and that those favoring retention and execution of the order will be present to meet whatever develops from these petitioners.

The decision of the Commission in the assigned car case was by a 7 to 4 vote. Unofficially, it is understood that the case was reopened by a vote of 6 to 5.

Proponents of abolition of the assigned-car practice point out that the United States Coal Commission, in its report, condemned this practice, although suggesting the advisability of some system of assuring transportation to those contracting for large coal supplies.

Dean Cooley Announces Resignation

Mortimer E. Cooley, dean of the College of Engineering and Architecture of the University of Michigan, announced his resignation as president of the American Engineering Council of the Federated American Engineering Societies at the opening session of a two-day meeting of the Executive Board of the Council held in Rochester, N. Y., Oct. 12.

In presenting his resignation to the Board, Dean Cooley said that he retires on account of ill-health. He also made it known that he has been granted leave of absence by the University of Michigan for the second half of the academic year of 1923-1924. Dean Cooley, who is now in his sixty-ninth year, succeeded Herbert Hoover as president of the Federated American Engineering Societies two years ago.

The Executive Board, it was announced, will call for nominations for the presidency of the Federation and Dean Cooley's successor will be formally chosen at the annual meeting of the American Engineering Council, executive organ of the Federation, to be held in Washington, D. C., early in January.

The Committee on Storage of Coal, W. L. Abbott, chairman, named by the Federated American Engineering Societies, appointed Dean F. L. Walker as field executive, who visited forty-four cities to obtain co-operation in the making

of the report. Eighty-five subcommittees formed in as many cities or states are considering the problem and will make reports. Forty-eight have done so already. The number of engineers serving on the main and subcommittees is 388. To date \$10,450 has been paid in or promised to finance the inquiry. The report should be ready about the middle of January.

Leland Coal Co. Expands in Illinois, Kentucky and Indiana

A reorganization and expansion of the Leland Coal Co., of Chicago, sets that concern up as an important operator of Illinois, western Kentucky and possibly Indiana. The company leases the six mines of the associated Union Fuel Co. in the Springfield (Ill.) district, and is now operating them. Also the Leland company is opening up an acreage it has purchased from the Verona Coal Co. at Verona, in Grundy County, Ill. There it will operate in the northern Illinois longwall region the only room and pillar mine on the Santa Fe R.R. The coal is under about 100 ft. of cover and varies in thickness from 5 to 10 ft. The mine may be developed to an output capacity of 2,500 tons a day.

At Waverly, Ky., 50 miles southwest of Evansville, Ind., the company has taken over the old Waverly mine in Union County, on the Illinois Central R.R. This mine, which has stood idle for several years but which is considered to be in excellent condition, will be rehabilitated at once by the Allen & Garcia Co., engineers, of Chicago, and put into operation. The company also is negotiating for the purchase of certain Indiana mines. The officers of the company are W. H. Leland, president; John D. Harris, secretary, and B. F. Bliss, treasurer.

Illinois Miners' Union Did Not Sell Herrin Strip Mine After All

It is authoritatively reported that the recently announced "sale" of the Lester strip mine, scene of the Herrin massacre of 1922, was no sale at all. The United Mine Workers of Illinois continue as owners of the property, having created the Mammoth Coal Co. with C. C. Shive as president, merely as an operating concern. The plant is now loading coal as fast as a dragging market will absorb it. The property was taken over by the Illinois branch of the miners' union in order to quiet large damage claims of the Southern Illinois Coal Co. against the union following the destruction of the plant and the slaughter of twenty-two non-union workers by an attacking mob.

PRESIDENT COOLIDGE HAS COMMENDED F. R. WADLEIGH for the service he rendered as Federal Fuel Distributor. In a letter to Mr. Wadleigh the President says: "I have received your final report as Federal Fuel Distributor under the provisions of the act of Sept. 22, 1922, your office having expired by limitation on Sept. 22, 1923. I have noticed the report with interest and am glad to have this résumé of the work concerning the distribution of coal during the past year. As I have had some occasion during the last few weeks to know of your work in this connection I want to take this opportunity to express to you my very cordial thanks for the able and efficient manner in which you have conducted the affairs of your office and your willingness to be helpful at all times. I want to assure you of my high appreciation of your services and express best wishes to you in whatever line of work you may take up in the future."

THE U. S. SUPREME COURT has allowed the motion of the government to advance argument in the appeal of the Federal Trade Commission against the decision of the Court of Appeals of the District of Columbia in the case of the Claire Furnace Co. The lower court ruled against the authority of the Commission to require basic industries, such as coal and steel, to furnish cost data reports. The case has been assigned for argument Dec. 3.

Coal Probes On in New York

Richard A. Enright, Police Commissioner of New York City, on Oct. 9 directed police commanders in every precinct to make a complete survey of the coal situation. The purpose is to assist the recent campaign undertaken by the Department of Public Markets to stop profiteering in coal and to co-operate with the state in case of another coal shortage.

The police were directed to ascertain from coal dealers the amount and sizes of the coal now in stock, the price per ton and the approximate amount they will obtain monthly. If in certain sections it is found that fuel is readily obtainable while in other districts with the same class of residents a scarcity is apparent, the reason for this will be brought to light and steps taken to remedy the situation.

Complaints from different parts of the city of inability to obtain coal since the settlement of the coal strike having reached the Federal District Attorney's office, Colonel William Hayward, U. S. Attorney, also has announced an investigation to discover whether he can obtain enough evidence to go before the Grand Jury and ask indictments.

Southwest Operators See Traffic Victory

An important traffic victory for the Southwestern Interstate Coal Operators' Association is foreshadowed in the recommendation made to the Interstate Commerce Commission by its examiner in the case of the association against the Arkansas Western Railway Co. The examiner recommends certain lower rates to the highly competitive consuming points of Kansas City, Omaha, St. Joseph and Leavenworth. He suggests that the Commission should find as follows:

"That the rates assailed on lump coal are and for the future will be unreasonable to the extent that they exceed or may exceed to Kansas City, Mo.-Kan., \$1.35 from the Rich Hill group, \$1.60 from the Pittsburg group, \$2.75 from the Arkansas-Oklahoma group, and \$1.35 from the Spadra group; to St. Joseph, Atchison and Leavenworth, \$1.65 from the Rich Hill group, \$3.05 from the Arkansas-Oklahoma group, and \$3.45 from the Spadra group; to Omaha and points taking the same rates, \$3.70 from the Arkansas-Oklahoma group and \$4.05 from the Spadra group; and to Sioux City, \$3.10 from the Rich Hill group, \$3.35 from the Pittsburg group, \$4.20 from the Arkansas-Oklahoma group, and \$4.55 from the Spadra group.

"That the rates assailed on slack coal are used and for the future will be unreasonable to the extent that they exceed or may exceed to Kansas City, \$1.10 from the Rich Hill group; to St. Joseph, Atchison and Leavenworth, \$1.35 from the Rich Hill group and \$2.75 from the Arkansas-Oklahoma and Spadra groups; to St. Joseph, \$1.60 from the Pittsburg group; to Omaha and points taking the same rates, \$3.35 from the Arkansas-Oklahoma and Spadra groups; and to Sioux City, \$2.80 from the Rich Hill group and \$3.85 from the Arkansas-Oklahoma and Spadra groups."

Gompers Again Heads Federation of Labor

Samuel Gompers was re-elected unanimously as president of the American Federation of Labor just before the adjournment of the forty-third annual convention, at Portland, Ore., Oct. 12. Addressing the convention just before its close, Mr. Gompers, who is 73 years old, declared that the gathering had given notice that a cleavage had been made between those loyal to organized labor and those who, boring from within, had sought to stab the labor movement in the back. "The results of this convention," he said, "will make for solidarity in the ranks of labor."

All the present officers of the Federation were re-elected. In reviewing the convention's work Mr. Gompers referred to the expulsion of William F. Dunne, delegate from Butte, Mont. "This is a convention of organized labor," he said, "and any man who is hostile to labor has no right in this convention. I feel that the action taken has clarified the atmosphere. I think we have been entirely too lenient toward those who have been boring from within. Those men

who meet at midnight in the forest, plotting not only against the government but against the labor movement can go ahead as they please, but they must do so outside the ranks of organized labor."

Commission Issues Report on Wage Rates In the Bituminous Coal Industry

The U. S. Coal Commission issued its report on Wage Rates in the Bituminous-Coal Industry, Oct. 17, the examination having been made by W. E. Fisher, of the Wharton School of Commerce and Finance of the University of Pennsylvania. This is one of several studies made under the general supervision of Dr. Willits and was co-ordinated with his investigation of the Causes of Strikes as well as on Miss Bezanson's study of Earnings. The report on wage rates comprises 54 typewritten pages with an appendix of 102 tables showing rates and changes in rates for specified occupations from 1912 to 1923.

Wadleigh, in Final Report, Says Nation Is Assured of Full Winter Coal Supply

In his final report to the President, made public Oct. 16, F. R. Wadleigh, Federal Fuel Distributor, says the country can feel assured of an adequate supply of coal during the coming winter. His office, which was created during the strike emergency of 1922, expired by limitation Sept. 22.

"The railways are successfully meeting to-day's unprecedented traffic demands, and it is expected that the transportation of coal and other fuels will be adequately handled during the coming winter season," says the report.

"Since there is no reason to anticipate any substantial interference with production of coal during the winter months the country may be reasonably assured of an uninterrupted supply of this commodity so necessary to its health, comfort and prosperity."

Coal shortage last winter, the Federal Distributor said, was largely nothing more than anthracite shortage. He said domestic consumers used substitutes with great reluctance and that other fuels were usually available.

Domestic consumers have not stored an unusual quantity of coal, but no difficulties during the coming winter are foreseen by Mr. Wadleigh.

Pinchot Consults Operators on Coal Prices

Governor Pinchot held a conference Oct. 15 at Harrisburg with S. D. Warriner, chairman of the Anthracite Operators' Policy Committee; W. J. Richards and A. B. Jessup and discussed with them "available methods of reducing the price of coal to the consumers to the level of last year." The conference was held at the invitation of the Governor.

The operators present were members of the producers' negotiating committee which met with the miners' union officials last month and agreed on the anthracite wage contract now in effect. W. W. Inglis, the fourth member of the committee, was not present. The result of the conference was not divulged but Governor Pinchot said that the operators would return for another conference next week.

IN A LETTER sent to President Coolidge Oct. 15, Governor Silzer of New Jersey urges that the coal situation be included in the subjects considered at the conference with state executives at the White House next Saturday. "The situation is one that can only be dealt with and solved by the national administration (with some aid from Pennsylvania)," wrote Governor Silzer. "Nevertheless, I am sure that the Governors will be glad to aid you by stimulating public sentiment in their respective states if you have an effective plan to relieve the people."

THE INTERSTATE COMMERCE COMMISSION has announced that hearings in the Virginian case, Finance Docket 2812, have been postponed until Oct. 31 at Washington before Examiner Charles D. Mahaffie.

Production and the Market

Weekly Review

Production of soft coal has been affected by the resumption of anthracite mining; demand is slower and prices show a further decline. The spot market is quiet, while deliveries of contract coals are being curtailed wherever possible. In the West warm weather has curtailed the demand for domestic coals, while in the East reserve stocks together with reduced industrial operations in various lines have affected the steam-coal situation.

For the sixth consecutive week *Coal Age* Index of spot prices of soft coal shows a decline. On Oct. 15 it registered 185, a drop of five points from the previous week, and of twenty points since Sept. 10. The average price of soft coal was \$2.24 on Oct. 15, a drop of 6c. from the preceding week and of 25c. from Sept. 10.

OUTPUT DROPS; REBOUND LOOKED FOR

Production of soft coal for the week ended Oct. 6 is estimated by the Geological Survey at 10,782,000 net tons, a decline of 565,000 tons when compared with the previous week's output, but it is expected that last week's production will show a partial recovery from this loss. Production of soft coal during the first 236 working days of this year was 424,257,000 net tons, which has only been exceeded once during the corresponding period of the past six years in 1918 when it was 454,515,000 tons.

Movement was slow in the Chicago market. "No bills" affected the Illinois mining operations, while the situation in western Kentucky is anything but satisfactory. Mine closings in Illinois and Indiana are growing in number.

Dullness prevails in the Ohio markets, with inquiries scarce. The Pittsburgh market is quiet and buyers are slow to show any interest in the situation. In New England the steam-coal market is in bad shape and trade is stagnant. Reports of further curtailment in the textile industry are current, either by a complete

shutdown of some mills or a reduction in working time.

Output of anthracite was 2,015,000 net tons during the week ended Oct. 6, indicating that the industry has recovered from its strike. While the production showed a decrease of 10,000 tons from the preceding week it equals the weekly rate of output that prevailed just before the strike and exceeds by 60,000 tons the average weekly rate in the first five months of the present

	Week Ended Oct. 8	Season to Oct. 8
Cargo.....	785,199	22,799,322
Fuel.....	53,311	1,245,839
Totals.....	838,510	24,045,161

coal year. Cumulative production during the calendar year to Oct. 13 amounted to 73,279,000 tons, which is more than two and a quarter times that of the corresponding period for 1922. Domestic sizes of anthracite are in heavy demand, but the steam coals are hard to move.

Movement of coal from the lower Lake ports remains around 800,000 net tons weekly, with cumulative shipments of cargo and fuel coal for the season totaling about 24,045,000 tons.

There is no activity in the export market. Inquiries are few and chartering of vessels is on a slow scale.

(a) Subject to revision. (b) Revised from last report.

There is no sign of improvement at Hampton Roads, but dumpings there for all accounts during the week ended Oct. 11 was 339,332 net tons, an increase of 15,239 tons from the previous week.

Bituminous screened coals, Welsh anthracite and coke are practically out of the market as substitutes for anthracite. There are few inquiries being received, while prices for coke show a further decline from last week.

Middle West Still Unhappy

The whole Midwest coal region continued in a state of funk during the past week. Warm weather slacked down lump sales and stalled practically everything except a little call for fine coal. The shortening of work time had the effect of tightening up a trifle on screenings prices, which last week appeared to be going down without a bottom to touch. A slight rebound was noticed in southern Illinois screenings on the Chicago market, lifting the "low" spot quotation from \$1 to about \$1.20, and central Illinois from 60c. to about 75c. Improvement in prices that are as low

as those, however, is not particularly stimulating when the domestic sizes are not gaining strength.

The mining fields of Illinois are all suffering from "no bills." This affliction has spread from the fine sizes and nut up to domestic lump in the central Illinois territory, though in the Standard district, which offers the cheapest coal in the state, several mines are oversold on lump. Most of the operations in that field can place all the lump they can load at \$2.50@3.15. Shutdowns throughout the state and in Indiana are growing more numerous week by week.

St. Louis at a Standstill

Domestic business in St. Louis is at a standstill. Dealers' trucks and wagons are laid up. Yards are billed up, coal is on demurrage and yard owners are cancelling orders and stopping shipments. Reports from the country show that a similar condition exists everywhere throughout the Middle West on account of mild weather. The little call in evidence has been for a middle grade of medium-priced coal. Some dealers are eliminating Franklin County altogether. Wagonload steam shows some improvement and continues to hold its own in a small way. Carload steam

* Net tons, f.o.b. mines.

† Advances over previous week shown in heavy type, declines in italics.

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

is hard to find. There is no demand for smokeless, anthracite or coke. Country steam is about as hard to find as in St. Louis and everybody is waiting for cold weather.

Kentucky Prices Bump Bottom

The situation in western Kentucky is anything but satisfactory. Lack of steam demand has resulted in screenings working lower, until the market is quoted as low as 50c. a ton for pea and slack and 75c. a ton on nut and slack, while mine-run can be had at from \$1.50 upward. In prepared coals the market holds fairly well, but an average of top prices of prepared and top prices of screenings makes a realization too low to allow many mines to break even.

Car supply is reported at from 87 per cent on one line to 134 per cent on another railroad, which is making it possible to load more cars than the market can well absorb. Steam demand while good is being supplied by very cheap screenings.

The Louisville coal trade is reported as quite dull with a little coal moving at give-away prices. Steam coal in Louisville is lower than at any time since the early part of 1922. Western Kentucky screenings are being offered at 50c. a ton and up, while western Kentucky as well as eastern Kentucky nut and slack is being offered at a minimum of 75c. and ranging up to \$1, with some 60c.

stuff reported from eastern Kentucky. With screenings so cheap the demand for mine-run is almost nothing.

Northwestern Trade Barely Alive

During the past week there has been little doing in the Northwest except a casual movement of anthracite. The increase of from 25c. to 80c. on domestic sizes at the various Northwestern markets had a restraining influence on even that standard trade. Warm weather simply flattened the market out leaving little to look forward to except a cold snap.

This condition produced some reductions in prices of various soft coals. At Milwaukee retailers cut Pocahontas screened coal \$1.25; mine-run, \$2.50, and smithing coal, \$3. West Virginia screened was shaded 25c., and Illinois and Indiana domestic sizes, \$1.50. These cuts resulted from reductions at wholesale of nearly the same amounts. Kanawha gas mine-run was dropped 50c. At Duluth no further reductions were made. In the region about Minneapolis the market is so glutted that various cuts have been made to hold business and much "snowbird" coal has penetrated into the territory. There is little demand anywhere in the Northwest for coke or the briquets around which a small industry has developed.

Shipments from the docks at Duluth-Superior harbor continued heavy last month, a total of 23,174 cars of coal going out. This compares with 23,914 cars in August and 16,178 cars in September of last year. Shipments to the docks continued good last week with thirty-six cargoes arriving, of which three were hard coal. Twenty-seven cargoes are reported on the way, of which three are hard. Every indication points to a continuation of the movement. It is safe to say, from present indications, that a surplus of bituminous will be on the docks when navigation opens in the spring.

October receipts at Milwaukee by lake thus far aggregate 42,200 tons of anthracite and 144,090 tons of soft coal, making the season's receipts 675,938 tons of the former and 2,229,434 tons of the latter, or 2,905,372 tons in all.

Western Market Low Too

The Southwest is able to sell a little domestic lump coal these days, but little else. Steam continues to drag heavily. Further west, in the mountain country, Colorado market conditions remain practically unchanged with the trade experiencing about as low a fall as the old inhabitants can remember. The mines are getting about 60 per cent running time, however, which would not be considered bad in many another coal region.

Utah operators feel a slight increase in business coming in not only from the mountain states but from the coast and the great Northwest. Running time averages about four and a half days. Domestic sizes sell rather easily but steam continues draggy. A suggestion of car shortage has appeared, but the trade generally sees no sound reason why it should become acute.

Ohio Markets Are Lifeless

Retail dealers and steam coal users in the Columbus market are playing a waiting game and there is no life in the situation. Householders are not buying to any extent and retailers are in the market for only sufficient coal to keep their stocks intact. Retail prices remain steady. Screenings are moving the slowest; some mines in the Hocking Valley and Pomeroy fields closed down because of their inability to sell their slack output. Mine-run, while not nearly as weak as screenings, is being bought according to present needs. Reserve stocks of steam sizes are sufficient for from sixty to seventy-five days. Cleveland reports that the dullness in market conditions is being felt now to a greater extent than a week ago. Inquiries are scarce and distress coal is affecting spot prices, as well as demand. Steam coal is not being stored to any extent. The general market is practically a buyers' market. Notwithstanding this condition, receipts of coal at Cleveland last week were reported as greater than in any week since the end of March, being about 300 cars over those of the preceding week. This increase, it is

said, is due to large disposals of distressed coal and the fact that a good quantity of coal is being bought on track rather than on orders being placed for shipment from the mines.

Markets for smokeless coals at Cincinnati begin to show signs of sliding, the dullness and weakness in Chicago and interior points reflecting on the local situation. Lake shipments are slowing up, which will result in the necessity of other means of disposal being found. Rejections continue to grow. Retail prices show little change locally, except where in a few instances dealers have cut the price on slack to \$4.25 and domestic lump to \$7.50. Smokeless grades remain unchanged.

Reports from 441 mines received by the Southern Ohio Coal Exchange show output to have been 171,714 tons during the week ended Sept. 29.

Pittsburgh Buyers Hold Off

The Pittsburgh market continues in the dumps, and everywhere it is said that it is almost impossible to sell coal. There is no well-established price on any description of coal, and sales are made at figures according to circumstances, but while the market is weak it is not certain that the average of all transactions is at a materially lower level than last week. Buyers seem to be particularly conservative about taking hold. There is a disposition to reduce stocks rather than to increase them. This, at any rate, is the attitude of some steel mills having byproduct coke ovens. Market conditions in Buffalo are flat, with complaints of poor business increasing.

New England Market in Bad Shape

To the trade in New England it seems as if the steam-coal market could not possibly be in worse shape. With factors pressing buyers to absorb cargoes that are on the market it is only natural that prices should be further depressed. No. 1 coal has been offered at \$5.80 per gross ton on cars Boston for spot shipment, and it is freely said that coal f.o.b. Hampton Roads could be purchased on offers down to \$4.60, or possibly less. In all directions trade is stagnant.

Even producers of quality grades from central Pennsylvania who supposed their output was reasonably well covered are seeking shipping instructions in the open market and offering material concessions from a price basis that was considered barely the cost of production. The less favorably known coals apparently find no market whatever, for nothing about them is heard in this market. Moshannon coals of fair grade are offering at \$2 per net ton and more than a few Pennsylvania coals have netted much less than this figure when disposed of at New York and Philadelphia piers.

At Hampton Roads there are no signs of improvement. There are accumulations at the piers up to the point permitted by restricted output and all the agencies find the going extremely hard.

Seaboard Soft Coal Market Quiet

The spot market for soft coal at New York is extremely quiet. Coal is plentiful and cargoes of distress coal can be picked up at prices below current quotations. Shipments of contract coals are being curtailed, with the result that fair tonnages of some of the better grades have been thrown into the open market. Conditions at Philadelphia show

no improvement and are far from satisfactory to those producers who some months ago elected to put the bulk of their tonnage on a spot basis. In order to keep their coals moving it is said that some producers holding contracts at high figures have been willing to modify those figures. The tidewater business at Philadelphia is being confined in the main to bunker loading, no clearances being reported last week, nor were any charters registered for future sailings.

Considerable quantities of Pool 9 and 71 coals are being offered in the Baltimore market on a keen competitive basis, causing the demand for the cheaper coals to fall off. Gas coals are holding up well. The market in West Virginia is described by operators as bad everywhere without regard to the grade of coal offered. Low prices on both high and low volatiles are no incentive to buyers. In the southwest Virginia fields "no market" losses are said to be responsible for the greater part of the cut in production.

No improvement is noticed in the Birmingham market. The amount of spot business was smaller, if anything, than for the previous week. A fair amount of contract coal and for coke manufacture is moving from the mines. Furnace mines have curtailed production because of the blowing out of a number of furnaces.

Shipments of soft coal to Lake ports during the week ended Oct. 8 amounted to 838,510 net tons, a decrease of 1,720 tons when compared with the previous week.

Anthracite Demand Absorbs Output

While demand for anthracite domestic coals continues sufficiently strong to absorb the output, quotations for the independent product are easier but retail dealers are not showing a disposition to buy heavily of these coals when it is possible to take care of their trade with company coals. Larger shipments would be welcome, many yards being bare of supplies, the retail dealers delivering the coal as soon as it arrives. In some sections it is difficult to move pea coal, consumers sticking to their favorite sizes. Movement of the steam sizes is slow and the smaller producers are selling their product at prices far below company figures. Some producers and dealers are initiating an educational program to induce consumers to use a portion of these sizes with the larger coals.

The market for coke and bituminous screened coals has almost disappeared, although some retail dealers carry small stocks.

The steady decline in the production of beehive coke continued during the first week in October, production being estimated at 313,000 net tons, a decrease of 8,000 tons from the previous week. Production during September is estimated at 1,373,000 tons, as compared with 1,494,000 tons in August. Production of byproduct coke during September was 3,112,000 net tons.

Foreign Market And Export News

British Coal Production Exceeds Demand; Firmer Tone Noticeable

Although production exceeds the demand, output of coal of Great Britain's mines is increasing, a cable to *Coal Age* giving the output during the week ended Sept. 29 at 5,575,000 tons, as compared with 5,005,000 tons the previous week.

A firmer tone is noticeable in the South Wales market and sellers are less disposed to make concessions for prompt shipments. The possibility of an early settlement of the Ruhr problem, an increase in German coal output and its effect on European coal markets are some of the factors which are reflected in the waiting attitude adopted by customers towards forward buying. European business is poor, except the trade with France which is good. Italian orders have increased slightly. Belgian buying is below normal, and Dutch and German business is quiet.

Improved demand for better classes of large coal has absorbed much of the accumulated stock, and also created a steadier tone. Some of the mines are badly placed, and there is plenty of coal to satisfy existing demands.

The Newcastle market is unchanged. The only bright feature in the market is that the operators have been able to book up a certain amount of fairly steady business which will keep the pits busy through most of this month.

Paris Retail Dealers Advance Prices

The French coal market remains firm. Retail dealers are receiving inquiries while prices are steady. Although conditions in the Ruhr are clearing, it is expected sometime will elapse before coal deliveries will become normal, and before any agreement is made effective the French mines, with the assistance of British, Belgian and Dutch coals, will have to meet the demand.

At its recent session the Miners National Congress asked the Federal Board to discuss with the various committees the readjusting and raising of wages throughout the mining regions.

Retail dealers in Paris have increased the prices on all coals, with the ex-

ception of British anthracite sizes, from 5 fr. to 12 fr. per ton.

During August coal production of the Nord and Pas-de-Calais mines amounted to 1,853,298 metric tons, as compared with 1,723,850 tons in July, while the output of coke from the same districts during the same period was 125,231 tons as compared with 118,690 tons in July.

Market at Hampton Roads Soft

Business at Hampton Roads was exceedingly dull last week, with the market softening, movement at the piers falling off, and inquiries slackening. Indications were that the business for the first half of the month would approach the low record for any similar period for the year.

Export business showed a tendency to decline, while bunkers was weak, and coastwise trade scarcely holding its own. The tone of the market was weak, and the outlook not bright. Shippers attributed the inactivity of the market to the fact that reserved stocks were being consumed.

Coal Strike Halts Czechoslovak Industry

The Czechoslovakian coal strike, which has completely stopped coal and partially coke production, is now in its sixth week, and threatens serious industrial results, says Acting Commercial Attaché, H. L. Groves in a cable to the Department of Commerce. A reduction in production of the principal Czechoslovak industries will probably result if this strike is continued. An embargo has been placed on all domestic coal stocks by the government and sales are permitted only by special license. The stocks of coal on hand, however, are reported as still sufficient to meet all the current essential needs of the government and industries. Imports of Silesian coal to relieve the situation are increasing considerably.

News Items From Field and Trade

ALABAMA

An adjustment of wages by the Woodward Iron Co. at its Dolomite Mines Nos. 1 and 2 resulted in a temporary suspension of work on the part of miners at those operations on Oct. 1. However, all differences were satisfactorily settled and the men returned to work. The slump in the price and demand for pig iron and coke, officials explained, necessitated a reduction in production cost in order to allow any margin of profit on pig iron and coke in the present market. Operations at other mines where the reduction was put into effect were not interrupted.

The Town Creek coal mine, near Empire, Walker County, has been sold by J. E. Creel to Elmer Faucett, of Dora, for a consideration of \$10,000.

The Cullman Property Co., of Cullman, has sold to Charles Lark, of New York, mineral rights on 40,000 acres of lands in Winston, Morgan and Cullman counties for a reported consideration of \$100,000.

Fourteen hundred acres of coal land has been acquired in Bibb County, in the Cahaba coal field, by W. R. Young, George W. Randall and associates. These lands are on the Louisville & Nashville and the Southern railroads and carry the Thompson seam of coal, one of the best domestic coals in the state. It is understood that the property will be developed at an early date by the new owners, who are experienced operators and are now interested in several companies operating in the Cahaba field.

The Baker Towboat Co., of Tuscaloosa, has separated from its organization the Baker Coal Co., with a capital stock of \$10,000. Officers of the company are: J. E. Baker, president; G. E. Little, vice-president and general manager, and A. T. Baugh, secretary-treasurer, all of Tuscaloosa.

ALASKA

The bridge on the branch of the Alaska R.R. to the Healy River coal field, according to a telegram received Oct. 5 at the Interior Department, Washington, will be completed this month, making the coal mined in this district accessible for domestic and railroad consumption.

ARKANSAS

Judge Frank A. Youmans, in U. S. District Court, recently denied a motion to dismiss the suit of the Coronado Coal Co., Fort Smith, Ark., against the United Mine Workers of America. Judgment for \$2,223,000 is asked.

CALIFORNIA

Charles Piez, president of the Link-Belt Company, Chicago, announces the purchase of the Meese & Gottfried Co., of San Francisco, Los Angeles, Seattle and Portland. The improvement in distributing facilities effected by the consolidation and the additional manufacturing facilities acquired are expected to give the rapidly-growing industries of the Pacific coast highly economical and efficient service. The new organization will be known as Link-Belt Meese & Gottfried Co., with headquarters at San Francisco. The officials will be: Charles Piez, chairman of the board; B. A. Gayman, president; Harold H. Clerk, vice-president and sales manager; Leslie W. Shirley, treasurer; Richard W. Yerkes, secretary.

COLORADO

A gas explosion in the mine of the Midwest Coal Co. at Palisades, Oct. 7, killed Walter Scott, the manager, and five workmen. Investigation into the explosion was started by Coroner E. A. Krohn, Oct. 8, when all but two bodies had been removed.

ILLINOIS

The Hickory Grove Coal Co., an organization with headquarters in Rochester, N. Y., has purchased 120 acres of land

about two miles south of Riley, for a striping mine, and expects to begin loading coal soon. The mine may have a capacity of about 2,000 tons a day or about 40 carloads. The company has purchased steam shovels and other equipment. The E. I. & T. H. lines are at present building switches from their main lines to the new field. The new concern has extensive striping mines in Ohio and West Virginia. L. A. Fitch, of Rochester, N. Y., is president of the company and the local operations will be supervised by J. A. McLean, recently in charge of the company's mine at Clarkburg, W. Va.

The Central Illinois Public Service Co. through a consolidation becomes the owner of the mammoth power station under construction on the Mississippi river at Grand Tower, and of the double-circuit 66,000-volt steel tower transmission line now being built to deliver energy from Grand Tower to West Frankfort, where it will be redistributed through the coal fields and communities of southern Illinois. Electric service is rendered 107 active mines in the coal fields of central and southern Illinois. Although more than 48,000 hp. is furnished to serve coal mines, the present connected business is slightly less than 32 per cent of the total amount of business of this character adjacent to the company's transmission lines.

The Madison Coal Corporation is erecting a new mine-rescue building at the Crystal Mine in Tilden. This new building will be equipped with every modern appliance for rescue work. The company also is building a new wash house and when this done it will have 621 lockers and 26 showers. This mine now employs 500 men.

Donk Brothers Coal & Coke Co. at Edwardsville, has completed a new shaft and tippie and coal is now being hoisted through the new skip. About 300 men are being employed at the mine. As soon as the underground workings can be extended the mine will employ 200 additional men.

Dr. F. C. Honnold, head of the Honnold Coal Bureau of Chicago, made an illustrated talk on "The Story of Coal" before the Chicago Rotary Club, Oct. 16.

The Dodds mine, near Carrier Mills, owned by the Dodds Coal Co., has resumed operations. The company has just completed installation of new screens and cleaning machinery which will give the mine a cleaner product than heretofore.

At Marion a night school in coal mining is now in operation under the supervision of Prof. H. W. Bradbury. About 200 miners are enrolled. Courses in technical training and in branches that are difficult for practical miners to obtain are offered. Graduates will be able successfully to pass state examinations for promotion in mining.

The Harrisburg Colliery Co. has completed the erection of 25 modern four-room cottages, near its plant at Harrisburg, to help relieve the housing shortage there.

Electrification of hoisting and other machinery at mine No. 16 of the Old Ben Coal Corporation at Sesser is about complete. With the exception of a few minor repairs on the tippie and additional work about the mine, everything is in readiness to resume hoisting again.

John Meyers has resigned as mine manager of the Majestic mine, at Du Quoin, and will accept a position as superintendent for a large coal company at Johnston City.

W. K. Kavanaugh, head of the Southern Coal Coke & Mining Co., which operates in the Belleville region, is sponsoring a new type of coal burner for domestic furnaces. It is called "The Electric Furnace Man." It is a coal hopper and small motor-driven stoker to be installed under any household furnace, aimed to burn any kind of small coal, even Standard district screenings, the cheapest coal now on the market, without making any smoke. The device has just been put on the market.

Two new coal mines near Lewistown have opened and coal is being hoisted. The Lindquist and Fleming Brothers mine, located on the John Bowen farm, is on a lease of 105 acres of thin vein coal. E. W. Duvall has begun the mining of coal from the shaft on the Griffith farm at the end of North

Railroad Street. Robert Nahm is operating his mine in the east part of Lewistown at full capacity. Lewistown now has three mines.

INDIANA

In accordance with agreements reached several weeks ago, concessions for mining coal underlying the Wabash River from the State Department of Conservation to the Grasselli Chemical Co. and the Miami Coal Co., have been recorded at Terre Haute. The companies will pay a royalty of 10c. a ton. Engineers of the departments are at work to determine the amount of coal taken from the state-owned ground before the agreement, to ascertain what sum is due to the state for coal already mined.

Reports from Clinton are to the effect that a party of Terre Haute men have been taking options on Helt Township coal land the past few weeks and it is now definitely known that options have been obtained on about 2,000 acres. The options are taken on the big waste of farm land lying between St. Bernice and Summit Grove. There is believed to be a rich deposit of coal under most of the land. One hundred dollars an acre has been the prevailing price for coal lands in that township.

Clem J. Richards was appointed receiver for the Sugar Valley Coal Co. Monday, Oct. 8 by Judge John E. Cox in Superior Court of Vigo County immediately after a suit had been filed in that court against the company by Frank M. Steiner, seeking payment of \$5,000 alleged to be due and asking for a receiver. Mr. Richards' bond was fixed at \$50,000 as receiver and he was directed by the court to close the mine and employ men to care for the property.

A movement for a uniform eight-hour day for all labor employed in connection with coal mining in District No. 11, U. M. W. of A., has been launched by local union 2,648, located at Shirkieville, in behalf of mine firemen. The action taken by this local in the form of a resolution adopted sets forth that mine firemen are compelled to work ten and twelve hours a day, "which is not in line with the miners' constitution." The resolution places the local on record as favoring a uniform work day and calls upon other locals in the district which are in favor of a shorter work day for firemen to pass resolutions to that effect.

Suit for recovery of about \$2,500 for rents due for use of coal lands was filed by Milton Webster against the Otter Creek Coal Co. in Superior Court at Terre Haute, recently. Along with the complaint was filed a copy of a contract between the two parties, in which the coal company guaranteed Webster \$300 a year or more for use of his lands at 80c. a ton. According to the plaintiff, this sum has never been paid since Jan. 1, 1912.

KANSAS

Involuntary bankruptcy proceedings have been inaugurated in the Federal District Court in Fort Scott, Kan., against the Acme Coal & Mining Co., asserting the liabilities are \$40,000 and assets half that amount. A Pittsburg bank is the principal creditor. The Acme has been operating a steam-shovel mine on leased land at Gross, Crawford County.

A. W. Dickinson, formerly general superintendent of the Western Coal & Mining Co., with operations in Illinois, Kansas and Arkansas, has entered the service of the Union Pacific Coal Co. in the capacity of safety engineer. Mr. Dickinson will have direct charge of all matters pertaining to mine safety, the Union Pacific Coal Co. operating some twenty mines in the State of Wyoming.

The Buckeye Shale Brick Co. has been chartered with a capital of 2,000 shares, no par value, for the purpose of mining coal. Incorporators are M. E. Kundmiller, Jean B. Clyde, Ralph W. Edwards, Pat D. Collins and A. K. Strong.

Holmes Wager has been appointed general treasurer of the Western Coal & Mining Co., with headquarters in St. Louis. He succeeds Edward S. Johnson, who recently resigned to assume a connection with a St. Louis building and loan association. Mr. Wager has been in the employ of the Western for 23 years. Beginning as billing clerk he became cashier and then general claim agent.

A new record for a single day's production in the Kansas field was established Oct. 5 by the Central Coal & Coke Co. in its mine No. 51, near Mingo. On that day the output from the one shaft was 1,433 tons. The mine had been idle two days. On Oct. 1 the production was 1,291 tons and on Oct. 2 it was 1,332 tons.

KENTUCKY

The coal operators association in Kentucky has decided to organize and maintain a coal co-operative insurance company of their own and carry their own risks. This step was taken as a protest against the action of the associated compensation insurance companies, which has filed with the Workmen's Compensation Board of the state an application to increase the compensation rate from a basic rate of \$3.40 to \$3.85.

The St. Bernard Coal Mining Co., of Earlington, operating a branch in Louisville under the management of W. B. Gathright, has arranged to install an exhibit at the second annual Better Homes and Building Exposition, during the week of Oct. 22. Mr. Gathright is planning to install a mine operation in miniature.

MINNESOTA

The County Attorney of Hennepin County has had an investigation on in Minneapolis for some days, seeking to ascertain if there is any conspiracy existing which results in the high cost of coal. The attempt has been made to show a collective understanding among members of the dock association as to high, uniform prices. This was disputed by the Twin City Coal Exchange, which is antagonistic to the docks. But exchange men testified that the prices were made at the instance of the producers and that the dock men had little to say about them. Dock association officers stated that the organization had nothing to do with prices. The advance of 75c. in anthracite due to the increase to the miners, will also be investigated. It is estimated that the receipts of 900,000 tons of hard coal for the season over the docks, now reduced to 160,000 tons, must have been put in hiding in order to take advantage of the increase in price. So the investigation is to be extended to the books and records of the railroads and dock concerns, to ascertain where the dock receipts have gone. County Attorney Olson expects to go to Duluth in search of evidence on this phase of the matter. The dock charge, amounting to \$1.90, also is to be investigated.

MISSOURI

The mine at Mosby operated by the Mosby Coal Co., has been leased by a new firm under the title of the Mosby Block Coal Co. Of the new company, David Lodwick is president, and John S. Lodwick is secretary and treasurer. Both are from Domestic, Ia. The mine has been closed several months because of sand and water, but inspectors after an examination, predicted no more trouble would be experienced. They explained the flow as due to the release of a stratum of the fluid material from between two strata of limestone, which finally have come together, thus damming the flow.

W. J. Patterson, of St. Joseph, for the last twelve years connected with the F. M. Brinson Coal Co. in that city, has gone in the wholesale business for himself and opened an office in the Corby-Forsee Building.

W. K. Kavanaugh, president of the Southern Coal, Coke & Mining Co., of St. Louis, was appointed foreman of the new grand jury at St. Louis, which was recently impeached for the October term of court.

One hundred and eighty miners employed by the Elmira Coal Co. in its mine at Elmira, have returned to work, pending arbitration, after having been out on strike six weeks as a result of a disagreement between the company and one of its men over a claim of \$45. The room in which the man was working encroached upon a railway right of way, and he was laid off while another room was being made ready. He demanded \$45 payment for this idle time. Other miners, thrown out of work by the same cause, made no claim against the company.

A. B. Jefferis has started the Big River Coal Co. at St. Louis. He is the son of J. A. Jefferis, well known in the Middle West as manager of the Kerens-Donnewald Coal Co.

MONTANA

The King Coal Mining Co. has been incorporated for \$250,000 at Aberdeen, S. D., by James M. Brown, H. E. Kenyon and K. K. Kearney to purchase and operate the Star Coal Co.'s property at Musselshell.

OHIO

The October term of the U. S. District Court at Cincinnati shows a number of coal disputes that will have to be ironed out in the court.

The Columbus-Pocahontas Coal Co. has been organized by Columbus capitalists with a capital stock of \$500,000, its principal office to be at Columbus. Interested as incorporators in the new concern are F. A. Mossgrrove, H. N. Bargar, N. D. Kerns, R. T. McClure and W. T. Thompson, all of Columbus.

The Cincinnati Credit Bureau, backed by that branch of the American Wholesale Coal Association, is again functioning. Offices have been opened on the 29th floor of the Union Central Building, and J. E. Phillips, who was connected with Sanborn's Blue Book for several years, is now in charge.

The Columbus Board of Education will open bids Nov. 8 for 1,000 tons of Hocking nut, pea and slack for the Central High School building, which is nearing completion. The proposal terms provide that it must be free from dirt and must be delivered to the building.

The City Ice & Fuel Co., Columbus plans the building of a large retail yard at West Broad St., and the Big Four tracks to supplement yards already in operation. The yard will be equipped with modern loading and unloading equipment as well as other machinery.

The Columbus-Pocahontas Coal Co., which will have headquarters in the Hartman Bldg., Columbus, has been chartered under the laws of West Virginia with an authorized capital of \$300,000 for the purpose of operating mines and holding coal properties in the smokeless field. No announcement has been made of the properties to be taken over. The incorporators are N. D. Kerns, R. D. McClure, W. T. Thompson and F. A. Mossgrrove.

Papers have been filed with the Secretary of State increasing the authorized capital of the Long Hollow Coal Co., of Columbus, from \$25,000 to \$120,000.

The Swan Creek Lumber & Supply Co., Toledo, has purchased the retail coal business formerly conducted by the Fort Meigs Coal Co. The deal was closed Oct. 1 and the yard temporarily has been placed under the management of Henry S. Wingard. A new company, to be known as the Swan Creek Coal & Coke Co., will be chartered to handle the retail coal business from the new location. Improvements to the amount of \$25,000 are planned.

The Moss Run Coal Co., Bellaire, has been chartered with a capital of \$30,000 to mine coal and operate coke mines. Incorporators are Robert C. Williams, Herman R. White, R. N. Shaver, Fred McConn and Robert C. Brown. Mail will reach this company at R. F. D. No. 1.

Fifty thousand tons of coal came into the Cincinnati harbor from Kanawha River points the latter part of the first week in October, making the largest single shipment of coal that has been brought down from the upper reaches by water since the Ohio River was canalized. This coal was collected at the mouth of the Kanawha River and was wafted down on the waves created by the lock and dam system on which the government has spent millions of dollars. Eight fleets in all were brought down and nearly all were represented by Cincinnati coal merchants. Some of this coal continued on down the river destined for Louisville and midway points, but the most of it was either transferred directly to the rails or went into stockpiles at Cincinnati. Coal men point to this as a clear indication of the price having at last hit below the cost of production even to mines that have the least overhead to bear.

The Whittier-Crockett Coal Co., of Columbus, has installed a \$60,000 tippie at its mine near that city. It will handle 2,500 tons of lignite daily.

OKLAHOMA

Bituminous coal mines of Oklahoma produced 2,802,551 tons of coal valued at \$11,527,000, during 1922, according to statistics just made public. The McAlester district proved the most productive, with an output of 1,022,242 tons, valued at \$4,244,000. The value of the coal produced in the other fields is as follows: Coal County, \$371,000; Lattimer County, \$903,000; LeFlore, \$851,000; Okmulgee, \$3,340,000; Tulsa, \$986,000, and Craig, Haskell, Muskogee, Rogers, and Wagoner Counties, \$837,000. The average value of the Oklahoma coal was \$4.11 per ton, and the number of miners employed during the year was 7,828, of whom 6,500

worked underground. The average number of days during the year worked in the McAlester district was 128, while the average for the entire state was 114. The conversion of many railways and industrial plants to crude oil-burning types of boilers has given the coal-mining industry a distinct setback, but the depletion of oil stocks and a let-up in drilling operations give the coal mining industry a brighter outlook.

PENNSYLVANIA

The Mahoning Coal Co. has declared a dividend of \$10 on the common stock, payable Nov. 1, to stock of record Oct. 22. This makes \$30 a share declared so far on the common stock this year.

Jas. M. McIntyre & Co., of Rommel, have contracted with the Roberts & Schaefer Co. for a complete steel tippie and reinforced concrete screening bin to be built at their mine at Rommel. The tippie will be complete with dumps, crushers, conveyors and rescreening plant.

The Winstead Coal Co., of Uniontown, will open a new mine in the Eighth pool, Monongahela River, where the company has 96 acres of coal, the seam of which is said to be 7 ft. thick. The opening will be made about 500 ft. above Lock No. 8 on the right bank of the river.

Employees at two collieries of the Glen Alden Coal Co., who walked out last Oct. 6, protesting that they had not received the 10-per cent increase in wages granted under the terms of the new agreement, returned to their places Oct. 9. They decided to leave the adjustment of their grievances to union leaders. A third Glen Alden colliery was still idle, but it was expected the differences there would be speedily adjusted.

The general grievance committee representing the union mine workers of the Hudson Coal Co. voted Oct. 9 to call off the strike which had been in effect at nineteen of the company's twenty-two collieries and authorized the resumption of work Oct. 10. More than 19,000 men were affected. The committee decided to present its grievances in regular form, first to the district union officials and finally to the anthracite board of conciliation for adjustment. This action was taken on advice of officials of the United Mine Workers, who had declined to sanction the walkout. Production was curtailed approximately 60,000 tons by the two-day strike, which company officials declared was a violation of the new wage contract.

The Pittsburgh Steel Co. has called a special meeting of stockholders for Oct. 30 to vote on the proposal to transfer all the coal and coke properties of the company to the Monessen Coal & Coke Co., all the stock of which will be sold for the present by the steel company.

The three judges of the Common Pleas Court of Schuylkill County started hearings Oct. 8 on the appeal of the coal companies from the triennial assessment of 1922. All of the big coal land owners are represented in the appeals, the Reading Girard Estate, Lehigh Coal & Navigation, Madeira Hill, Lehigh Valley, Susquehanna Collieries Co. and Calvin Pardee holdings being represented by a score of attorneys. The court will hold continuous sessions on the appeals which originated in every township and borough in which there are coal holdings and it is estimated that a month will be required to hear the various appeals. The companies are appealing from a change in the taxation of coal lands from \$62,000,000 to approximately \$500,000,000. C. A. Snyder, State Treasurer, is heading the legal corps of the County Commissioners while Cyrus G. Doerr of Reading, and A. L. Williams of Wilkes-Barre, are among the attorneys representing the coal companies.

Thomas Kennedy, of Hazleton, president of District No. 7, United Mine Workers, has been appointed a member of the State Welfare Commission by Governor Pinchot.

The Oliver & Snyder Steel Co. has closed down its Oliver Nos. 1 and 2 plants near Uniontown, leaving the No. 3 plant running. The Champion-Connellsville Coke Co. also has closed down its plant near Brownsville.

The two properties of the American Coke Corporation, in Fayette County, which were advertised to be sold at receiver's sale on Oct. 4 were bought by W. M. Robinson, of Pittsburgh, member of the law firm of Reed, Smith, Shaw & Beall representing the Union Trust Co., American No. 1 plant, composed of 142 beehive coke ovens, about 30 acres of available unmined Pittsburgh or Connellsville seam coal, and machinery, plant and dwellings, sold for \$125,000. American No. 2 plant, composed of 240 beehive coke ovens, 170 acres of Sewickley seam coal and 17 acres of Pittsburgh or Connellsville

seam coal, with machinery, plant and dwellings, sold for \$75,000. No. 1 plant is located at Linn, near Brownsville, on the Pennsylvania R.R. and has been working off and on for the past few months, but was closed down by the new owner. No. 2 plant is at Martin, near Masontown on the Monongahela R.R. It has been idle for several months. The Orient plant will be sold Thursday, Oct. 25, and consists of 480 beehive ovens and 461 acres of Pittsburgh or Connellsville seam coal, with elaborate machinery and a large number of dwellings.

TENNESSEE

T. C. Miller has resigned as mine superintendent for the Sterling Coal & Coke Co. of Mauring, to accept the general superintendency of the Storm King Coal Mining Co., of Storm King, Ky.

UTAH

The Union Coal Co. has filed articles showing capital of \$500,000. The company takes over Carbon County property. C. N. Strevel, Salt Lake City, is president. He owns 498,000 shares of the stock. W. B. Outcalt is secretary-treasurer of the company.

Title to what some regard as one of the richest undeveloped coal sections in the state has been cleared by a decision just handed down by Eli F. Taylor, register of the local land office. The Lund family, of Salt Lake City, descendants of the late Anthony H. Lund, high official of the Mormon Church, are favored by the decision. The Lunds applied for patent to the land following its survey in 1917.

The majority stockholders of the Lincoln-Kemmerer Coal Co., Ogden, were prohibited in an order issued by District Judge Barker, of Ogden, from disposing of the company's property in Wyoming until after a hearing on Oct. 15. This hearing was for the purpose of deciding whether or not a receiver shall be appointed for the concern, as requested by the minority stockholders. Petitioners maintain that the defendants have allowed the property to deteriorate by allowing the mine to fill with gas and water and the timbers to rot, for purpose of selling to their agents, also that dividends from the property in the past have been diverted.

The Blazon Coal Co., of Salt Lake City, has applied to the Public Utilities Commission for permission to sell \$249,000 worth of stock with which to continue development of its property in the Point-of-Rocks district, Wyoming. It is the intention to build a railroad to this property. L. F. Rains, prominent as a promoter of the Columbia Steel Corporation, is president of the company.

The Salt Lake City office of the Sullivan Machinery Co. removed Oct. 1 from its old quarters in the Walker Bank Building to the Dooly Block, 121 West Second Street. B. B. Brewster is manager of the Inter-Mountain territory, comprising Utah, southern Idaho, eastern Nevada and western Wyoming.

VIRGINIA

The Chesapeake & Ohio Coal & Coke Co. has sold its mines at Stonegate, and will discontinue the operation of its Norfolk office Nov. 1, it has been announced. J. R. Routten, Norfolk manager, expects to go to New York to enter the home office of the company.

Offices of the Fort Dearborn Coal Co. have been moved from the Flat Iron Building to the Law Building, Norfolk, in order to be in the center of the business district. The Central Pocahontas Coal Co.'s offices have been moved into the Law Building, also.

WASHINGTON

Washington coal mining is the third largest industry of the state with between 5,000 and 6,000 men employed and with a normal payroll of \$11,000,000. The industry absorbs about \$9,000,000 worth of timber and mine supplies each year. Coal is mined in eight counties. The largest area of coal is in the Cle Elum district, where there is estimated to be 10,000 acres, according to a writer in Seattle.

WEST VIRGINIA

The coroner's jury at the investigation into the explosion at the Benwood mine of the Wheeling Steel Corporation late in September, conducted by the State Mines De-

partment of West Virginia and by the County of Marshall, brought in a verdict that the explosion was due to unknown causes.

Denial is made of the report that there has been any general effort on the part of operators in the Logan field to revise wages downward, although some companies are understood to have made a reduction for a short period at least. There does not appear to have been any general reduction made in the mining fields of southern West Virginia, however. In some of the non-union fields in the northern part of the state, however, it has been necessary to reduce wages to the extent of about 20 per cent in order to continue operations, but such a cut does not appear to have been general to non-union territory, although the fact that the present selling price is below the cost of production.

The sum of \$200,000 was involved in a deal in coal land in Logan, Mingo and McDowell counties in which Sheriff Don Chafin of Logan County, one of the best known figures in southern West Virginia, figured as one of the principals, when a large block of coal land was acquired from Maynard Stiles, Hattie Dixon and Thomas Bullock, of Los Angeles. There are two seams of coal underlying the land, one being 4 ft. thick and the other 7 ft. thick. This is said to be one of the largest pieces of undeveloped coal land which has changed hands in southern West Virginia in a long time, constituting the last remnant of the famous King land grant, which was in the courts under litigation for so long a time.

Plans for maximum production with minimum use of mine workers have worked out satisfactorily at the plant of the Hardy Coal Co. on the Norfolk & Western, where there are about 6,000 acres available for development. The company shipped 2,000 tons in May, 10,000 tons in June, 18,000 tons in July, 23,700 tons in August and 27,000 tons in September and expects to produce at the rate of 50,000 tons a month by April next. It is stated that with a little further construction work it will be possible to mine and ship coal at the rate of 1,000,000 tons a year. The mine is said to be one of the best equipped mechanically in the country. Although in operation a short time, the Hardy mine ranked tenth among a total of three hundred mines on the Norfolk & Western during September.

After smouldering for 18 months, a mine fire at the No. 2 mine of the Boone County Coal Corporation at Sharples has at last been extinguished. Although the fire did not cover a wide area nor burn very fiercely, yet it proved to be exceedingly stubborn owing to the fact that after frequent sealings, the air was still able to filter through the roof, furnishing just enough oxygen to keep the fire going. It was only recently that the sealing shut off all air and then the mine was flooded late in September. Little damage has been done the mine.

Although the strike at the Lowesville plant of the New England Fuel & Transportation Co. involving about 350 miners apparently was settled Oct. 3 after they had been on strike a week, the men were called out again on Oct. 6. The men walked out late in September because the company desired them to bore three holes before shooting down the coal. The men returned to work and agreed to drill three holes, but remained at work only a few days, when they were called out. On Oct. 8 an agreement was reached between sub-district officials and the management to arbitrate the differences between the men and the company.

The Minok coal mine, idle for some months, pending improvements, is now ready for work. The headframe has been extended, making the top about 100 ft. high. This addition will permit the installation of new sheave wheels in a short time. Two new 13-in. steel hoisting cables have been installed. A new deep well pump with cylinder 600 ft. down has been installed. A concrete floor of a 500-ton lump coal pocket is soon to be laid.

WASHINGTON, D. C.

An insistent demand has arisen in the coal-mining sections of the country for more precise knowledge in connection with the use of electricity in coal mines. Since the problem is a national one and involves the safety of large numbers of men working in mines, it is urged that the federal government should provide the funds to undertake the necessary study of the problem, which is becoming more and more acute. Alternating current is being used to a greater extent in coal mines, because of the economies of transmission which are

not possible when direct current is used. Mines are becoming more extended and the use of electricity is increasing with the result that the cost of this item is becoming a factor and is resulting in many properties being changed over from direct to alternating current. The number of accidents has increased materially with the more general employment of alternating current. The point has been reached where mine inspectors are in doubt as to the advisability of allowing the continuance of the use of alternating current. Mine operators, to whom a change in the electrical system means large expenditure, are of the opinion that the relative danger of the two forms of current should be established before any drastic regulations are put into effect.

The case of the Federal Trade Commission vs. the Claire Furnace Co. has been given a special preference by the U. S. Supreme Court. It will be argued before that Court on Dec. 3. In the case of the Corona Coal Co. vs. the United States, the Court calls upon the coal company to show cause why the appeal should not be dismissed.

The U. S. Supreme Court has been asked to review the case brought against the Pittsburgh & West Virginia Coal Co. and others by the Canute Steamship Co., Ltd. An adjudication in bankruptcy against the Diamond Fuel Co. was approved by the Circuit Court. The steamship company is a creditor of the Diamond Fuel Co. and has attached certain property of the coal company at Baltimore.

Quite contrary to the usual custom, the Supreme Court of the United States has reopened the case of Pennsylvania vs. West Virginia, in which the court held that local consumers are entitled to no preference in the use of gas in its flow through interstate pipe lines.

CANADA

The British Empire Steel Corporation reports September coal production at 412,850 gross tons as compared with 425,044 for September, 1922. Production for the first nine months of the year was 3,924,628 gross tons as compared with 2,836,352 tons for the corresponding months of 1922, an increase of 1,088,276 tons.

J. D. Galloway, provincial mining engineer for the northeastern division of British Columbia, just returned from a tour of inspection in the Peace River region, reports that the known coal area at Rocky Mountain Canyon is 40 by 60 miles in extent. The grade of the coal is semi-anthracite, and is markedly lower in ash than the majority of the Western coals. As a rule the seams are small, but there are an appreciable number of commercially workable seams. A shipment of 40 tons has been sent by water to Peace River Crossing, consigned to the Canadian Pacific Ry., which will give it a practical test to determine its steam-raising qualities. Mr. Galloway stated that if transportation difficulties were overcome he believed the coal would compete with Pennsylvania anthracite in Ontario markets. Mr. Galloway stated that he found the people much opposed to comparatively recent legislation reserving coal and oil lands, thus making it much more difficult to obtain coal and iron leases.

Definite steps have been taken in the Canadian province of Alberta to protect coal buyers against deception in the fuel they get. The government has enacted a law aimed to prevent substitution of poor coal for good by requiring the trade name, mine of origin, class and grade of every coal shipment to be recorded on all documents involving the coal. Fine and imprisonment up to six months are the penalties for infraction.

Alberta coal is in demand in Ontario, according to press dispatches. It is stated that in the City of Windsor, Ont., the City Hall was stormed by hundreds of citizens anxious to obtain some of the Western coal, which was being offered at \$14.50 a ton. In order that the distribution might be fair the authorities were compelled to limit each applicant to one ton. The regular price of coal at Windsor, it is said, is \$20 a ton and it is difficult to get at that price.

Forty-six tons of semi-anthracite from the Peace River country in the vicinity of Hudson's Hope have been delivered by scow to the Canadian Pacific Ry. to be used as a test of its steaming qualities in the locomotives of the E. D. & B. C. Ry., a subsidiary of the C. P. R. running into Edmonton. If it is a success, of which there is no question in the minds of the members of the coal company, it will mean the establishment of a new coal industry in northeastern British Columbia. Neil Gething, W. Gething, L. Gething, and Leslie Ayland, all of Hudson's Hope, are the promoters of the enterprise.

Obituary

William Harrison Conkle, 69, prominent pioneer coal operator of Sullivan County, Indiana, died at his home recently of a complication of diseases. He became suddenly ill the day before and his condition became rapidly worse, finally developing into double pneumonia and heart trouble. Mr. Conkle was born in Beaver County, Pennsylvania, Oct. 5, 1854. Surviving are the widow, two daughters, Mrs. Tine Huff and Mrs. Max Crowder, of Sullivan, and one son, W. E. Conkle, of Pekin, Ill.

Thomas Cunningham, 76, died recently at his home in Edwardsville, Ill. For the past 20 years he had served most of the time as county mine inspector for Madison County. Born in Scotland, he took up coal mining as a boy and came to Illinois at the age of twenty. He celebrated his 53rd wedding anniversary last December. Besides a widow he leaves five children.

Water Filters and Filtration Equipment. The Permutit Co., New York City. Bulletin 105. Pp. 23; 8x11 in.; illustrated. Covers the theory and practice of modern filter design and construction. Method of operation is shown by detail drawings.

Sullivan Machinery Co., Chicago, Ill., has just issued the following bulletins: **Rotator Hammer Drills.** 81-B. Pp. 31; 6x9 in.; illustrated. Describes new line of rotator drills redesigned to obtain increased drilling speed. **Ironclad Overcutter, Class CE-11.** Bulletin 79-H. Pp. 7; 6x9 in.; illustrated. A new type of machine is described for mining out dirt bands or partings midway of the coal seam so as to prevent mixing the dirt or impurities with the clean coal when it is loaded out. **"WA-6" Air Compressors.** Bulletin 77-G. Pp. 7; 6x9 in.; illustrated. Describes single-stage steam-driven straight-line air compressors. This bulletin is a reprint of a former edition. **Drill Sharpeners.** Bulletin 72-H. Pp. 32; 6x9 in.; illustrated. Describes the drill-steel sharpening machines of two types and their adaptation to making different classes of drill bits and drill shanks on solid and hollow steel.

Trade Literature

Type AA Reliance Induction Motors. Reliance Electric & Engineering Co., Cleveland, Ohio. Bulletin 5018. Pp. 14; 8x10 in.; illustrated. These motors are for two and three-phase alternating-current circuits. Details of construction are outlined.

Bristol-Fuller Controller Valve. The Bristol Co., Waterbury, Conn. Bulletin No. 319. Pp. 15; 8x10 in.; illustrated. For use with automatic temperature-controlling apparatus to control the flow of air and gas, steam, oil and other liquids. Describes some of the variations for which this equipment can be supplied.

Lopulco Pulverized Fuel Systems. Combustion Engineering Corp., New York City. Catalog L-1. Pp. 11; 8x11 in.; illustrated. Describes both the theory and mechanical features of the powdered-coal system installed by this company in some of the boiler plants in this country, and includes a section through a Lopulco-equipped boiler plant showing all the different elements of the system.

Type "AR" Squirrel-Cage Induction Motors. Allis-Chalmers Mfg. Co., Milwaukee, Wis. Bulletin 1118-B. Pp. 10; 8x11 in.; illustrated. A feature of these motors is the use of cast steel in place of cast iron wherever practicable.

A new illustrated circular just issued by the Davenport Locomotive Works, Davenport, Iowa, illustrates the various types of steam locomotives of large and small gage. This company specializes in locomotives for mine and contract work and has incorporated many new features of design in its locomotives that will prove interesting to the coal-mining engineer.

Two new bulletins of interest have just been published by the Atlas Powder Co., of Wilmington, Del. **"Move Your Oldest Stock First"** is the title of one which explains the advantages of stocking explosives in such a manner as to move the oldest stock first and thus always have the advantage of new supplies. This arrangement obviates the necessity of discarding

any old supplies which may deteriorate with age. The second bulletin is on the subject of **"Small-Diameter Dynamite Cartridges Inferior."** This is an extract from the Bureau of Mines Report by S. P. Howell and J. E. Crawshaw. This bulletin shows that as the diameter of cartridges of dynamite, gelatines, permissibles and other high explosives is reduced the velocity, sensitivity and efficiency also are reduced and the objectionable fumes given off when the explosion is detonated are increased. The loss in strength or efficiency is due to partial or incomplete detonation resulting from insensitivity.

Bulletin No. 43976 of the General Electric Co. covers **Charging Equipment for Motor Power Storage Batteries.** This bulletin describes charging equipment which has proved reliable and satisfactory in service. There are two classes of apparatus described in the bulletin: (1) Individual battery charging motor-generator sets with switchboards for Edison or lead batteries for (a) Non-automatic or (b) Automatic operation; (2) motor generator sets with switchboards for charging two or more Edison or lead batteries for (a) Non-automatic or (b) automatic operation. Due to the varied nature of the sizes of the batteries to be charged, of the requirements to be met in different localities, of the methods of charging, etc., no attempt has been made in this bulletin to show any but a small proportion of the equipment that is manufactured by this company.

"It Pays to Keep Boiler Tubes Clean" is the title of a new pamphlet recently put out by the Heine Boiler Co., St. Louis, Mo. A most interesting statement on heat transmission in this pamphlet is to the effect that tests have shown that one-fiftieth of an inch of scale deposited on steel plates reduce the rate of heat conduction 60 to 75 per cent. In addition, the scale prevents rapid transmission of heat to the water, thus causing the tubes to become overheated and their life greatly shortened. Mud deposited on the heating surfaces results in lower heat transmission—fuel waste—overheated and bagged tubes. It pays to keep boiler tubes clean.

The Rome Wire Co., Rome, N. Y., has issued the following bulletins: **Super Service Cord and Cable.** Pp. 16; 7x10 in.; illustrated. Size of gage, stranding, capacity amperes, diameter of two- and four-conductor cords, three-conductor and single-conductor flexible cable, concentric, two-conductor cables and parallel duplex mining cables are given. **Super Service Junior Cord,** especially adaptable for mine, telephones and other mine equipment is covered in this bulletin and also in a 3x6 four-page folder. **Welding Cable,** declared to be absolutely waterproof, is described in the 7x10 in. bulletin and in the smaller one, which also gives prices.

Gas Conditioning for CO₂ Recorders. Uehling Instrument Co., Paterson, N. J. Bulletin 116-A. Pp. 7; 9x11 in.; illustrated. Describes the "Pyro-Porus" filter, gas drier and gas purifier, three simple devices which are claimed to completely eliminate soot, moisture and sulphur. Small bore seamless-drawn tubing used for the gas sampling line also is described.

Hose Fittings. Schlangen Bros. Co., Chicago, Ill. Pp. 43; 6x9 in.; illustrated. Covers nozzles, sprinklers, connections, clamps, couplings, bushings, valves. The bulletin has an attractive appearance, being bound in heavy brown paper.

The Osgood Co., of Marion, Ohio, has recently issued Bulletin No. 236. This is in the form of a four-page folder illustrating and describing its new 14-yd. heavy duty steam shovel.

Association Activities

The board of directors of the Central Pennsylvania Coal Producers' Association and the executive committee of the Association of Bituminous Operators of Central Pennsylvania met Tuesday, Oct. 9, at the Lincoln Trust Building, Altoona, and re-elected B. M. Clark of Indiana, Pa., president; G. Webb Shillingford, of Clearfield, vice-president, and Charles O'Neil, of Altoona, secretary-treasurer of both organizations. John C. Forsythe was re-elected commissioner of the Association of Bituminous Operators and W. A. Jones was re-elected statistician of the Coal Producers' Association. Conditions in the field were considered in an informal discussion, one of the subjects taken up being the negotiations for a new scale that must be framed to take the place of the one that expires on April 1, 1924. The coal business is decidedly dull in the district at present, the general opinion among the operators present being that

it is due to overproduction, the extended use of fuel oil by the shipping interests and by the gradual development of electric power in the New England states, where there always has been a good market for central Pennsylvania coal. Operators present at the meeting who have visited the New England states recently declared that electric-power plants are springing up along the various rivers and the promoters contend that because of strikes in the coal regions, high freight rates and the tying up of the railroads during the extreme weather of winter, coal is becoming too expensive and the supply too uncertain. It also was reported that the use of oil as fuel is increasing by leaps and bounds and is adversely affecting the coal industry. It was shown that prices at the mines are so low now that there is no profit in the business.

Traffic News

The movement of freight cargoes through the canals at Sault Ste. Marie during September totaled 12,776,048 net tons, according to the monthly report of the U. S. Engineer's Office, as compared with 10,986,056 short tons in September last year. The movement of coal upbound was 1,945,344 net tons of bituminous and 73,461 net tons of anthracite compared with 2,353,745 net tons of bituminous and 10,805 net tons of anthracite in September a year ago.

A complaint against the present level of railroad rates on coal from Illinois, Indiana and Kentucky to Iowa cities was filed with the Interstate Commerce Commission Oct. 10 by the Iowa Board of Railroad Commissioners. Consuming territory of Minnesota, Wisconsin, Illinois, Missouri and Indiana, the petition said, has more favorable rates on coal than Iowa. The commission was asked to institute an investigation to fix a fair rate level.

Rates on coal from the Crescent group in West Virginia and Kentucky from the Pocahontas field and from other producing areas to various consuming points in Indiana have been attacked in a score of complaints filed Oct. 6 with the Interstate Commerce Commission on behalf of various Indiana consumers.

On Sept. 28 the Interstate Commerce Commission closed its hearing of the Louisville & Nashville R.R. and Atlantic Coast Line R.R. for exercising an agreement for a 999-year lease on the Carolina, Clinchfield & Ohio R.R., which is opposed by the Seaboard Air Line and other Southeastern railroads, which fear a monopoly. The Commission has given those interested until Oct. 29 to file briefs, for final argument of the case.

It was reported from Pineville, Ky., Oct. 4, that work had started on another 18-mile section of double track on the Cumberland Valley Division of the Louisville & Nashville R.R., several sections of which have been double tracked, in the plan of making this division a double-track affair from Corbin to Loyal, in an effort to give better service to tonnage from Bell and Harlan County fields. A 17-mile section of the Eastern Kentucky division of the road into the Hazard field also is under double track construction. If the L. & N. obtains its Clinchfield lease it will be in excellent position to give fine service to the shippers after connections are made from the Eastern Kentucky and Cumberland Valley divisions to the Clinchfield.

Coming Meetings

The West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers will hold its annual meeting Oct. 19-20 at Huntington, W. Va. Secretary-treasurer, Herbert Smith, Robson-Prichard Bldg., Huntington, W. Va.

American Welding Society, Oct. 24-26, Pittsburgh, Pa. Secretary, M. M. Kelly, 33 West 39th St., New York City.

Harlan County Coal Operators' Association, Nov. 21, Harlan, Ky. Secretary, E. R. Clayton, Harlan, Ky.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

Second National Exposition of Power & Mechanical Engineering, Grand Central Palace, New York City, Dec. 3-8. Managers, C. F. Roth and F. W. Payne, Grand Central Palace, New York City.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 24

NEW YORK, OCTOBER 25, 1923

Number 17

A Squeeze Can Be Helpful

"CONSOLIDATE!" has been the cry. "Let economic pressure squeeze these excess mines either out of business forever or else into big, well-operated groups. Then the problems of coal will be solved."

Today that economic pressure is hard at work. The weeding-out process in the coal industry is leading to consolidations. In the Middle West right now there are no less than three new consolidations forming and the stronger of the groups formed years ago are carefully choosing the new properties they would like to absorb. In nearly every case the absorbing company is making definite plans to rehabilitate the newly acquired mines so that those operations may have, by the aid of the best equipment and management obtainable, a chance for life.

The encouraging thing about all this is not that the number of mining companies is reduced. Merely eliminating such unfortunates is of no permanent value, for a new crop always is able to spring up from nowhere during each favorable coal season. The real gain to industry lies in the fact that every siege of adversity proves more convincingly than its predecessor that pot-hole methods of mining do not pay in the long run. The mining property that endures is the one that is efficiently equipped and managed.

Today the first act of wise men of coal, upon taking over a failing mine, is to equip and man that mine so that it may have a real chance to stand up under the shocks of a highly competitive industry. Such investing is going on all over the country. As it increases, the measure of engineering and management knowledge in the coal industry increases. Perhaps that is how sound consolidations solve the problems of coal.

Why Not Fix Girard Royalties?

FEDERAL Trade Commission activities are directed against an agreement alleged to have been entered into between a producing coal company and some wholesaling firms to divide profits at a time when Pennsylvania had established a production price. The question arises, why is the producer alone regulated? Why not also fix the royalties on coal, especially that owned by the Girard estate? Is the producing price of coal to be fixed and the royalty price to be immune? Is the agreement to pay a certain percentage of the selling price of coal to the Girard estate also a trade conspiracy? Why not prevent such contracts from being made?

The coal mined by the coal company to be investigated was produced in Pennsylvania and was sold in another state. Is the regulation of price in one state to prevent participation in a profit in another state? Is a coal company, compelled to sell coal at a restricted figure when it knows the buyer will sell at an unrestricted figure and pocket a large profit?

If so, where is the justice of such a proceeding? The

payment is alleged to be conditioned on this large profit being made. It is admitted by the commission that if the consumer did not have to pay it the producer was not to receive any part of it. It seems that what this company is said to have done discouraged profiteering by making it less profitable. According to the commission's statement the man who made the price was allowed to make only part of the profit and so had only that part of the margin to act as an incentive to profiteering.

Meanwhile, as S. D. Warriner said the other day, one of the worst profiteers in coal is the City of Philadelphia in the person of the Girard estate.

Firedoors in Coal Mines

SOME of our metal-mine engineers are opposed to reversible fans. They prefer firedoors, operated by hand or electrically. These, Charles A. Mitke says, are foolproof. It will be difficult to get any coal-mining man to assert this of any door. In coal mines generating explosive gas almost any readily closed stopping is a menace. They are necessary evils at best, not to be erected without due need, for the closing of one of them when it should be open or the opening of one of them when it should be closed may result in an explosion.

Even in a mine which does not produce explosive gas naturally or as the result of a mine fire, firedoors are not absolutely foolproof. A mine on fire generates carbon monoxide, and the closing of a door may baffle the air current and hold the monoxide in the workings. If that fire is confined to a mine portal or to a shaft the danger in a mine not normally generating explosive gases is inconsiderable, but if the fire is raging where men are working it may cause the gases to stay and spread in those workings and asphyxiate the workmen.

As it is easier for a single miner to close a door than for an individual to reverse a fan, a door is a dangerous facility, especially when it is not in charge of a responsible man. Still it is not clear that the superintendent would not feel safer if he had a few doors in his mine that could on occasion be unlocked and closed by a man entrusted for that purpose with a key, but he would have to be a reliable man, for the opening or closing of a door is fraught with as many unfortunate possibilities as the reversal of a fan. In fact, how is a fan reversed but by the opening and closing of doors?

At the Argonaut mine, in California, the fire was in the shaft, and firedoors would have kept the gases which were generated in the shaft and circulated by the fan from entering the workings. They would have served their purpose in one way better than a reversed fan, for the air would have been instantaneously stopped, and in another way worse than such a fan because the reversal of the air current would have rid the mine of such gas as the fan had before reversal driven into the mine.

Even in the case of the Argonaut fire the argument

for the fire door is not quite conclusive. However, it is tenable in comparison with a case where the workings are on fire and the shaft is not burning. The ventilation is needed in the mine itself, for it reeks with poisonous gas and is all the time generating more, and it is easy to imagine what might happen in a coal mine with explosive gas and open lights; and, be it remembered, a burning coal mine develops methane whether it is present normally or not. The gas from a coal fire, moreover, contains not only carbon dioxide, carbon monoxide and methane but hydrocarbons of various kinds that are exceedingly harmful to human life. In a shallow shaft and drift workings the right kind of gas mask in the hands of all the men would prove a greater security than either firedoors or reversible fans.

Beautify a Coal Mine? Certainly!

LORADO TAFT, American sculptor, declares there should be art and beauty in every industry—yes, even in coal mining. In coal mining? The average American operator, saturated, so to speak, with the gloom and dust and slime of the “dark industry,” achieves that well-known physical impossibility of pricking up his ears. Then he smiles paternally upon Mr. Taft. Has Mr. Taft ever seen a bituminous-coal mine? Is he familiar with the gulches and wastelands in which so many mine towns stand? Has he ever seen the dust and spillage and smoke that are inevitable around a top works? Does he know the attitude of the average miner toward things of beauty, such as green patches of lawn and well-papered and painted houses, which the company may provide? What chance is there for any art or beauty under such conditions?

Well, we are not going to argue that mine operators should erect marvelous figures of the huntress Diana to grace mine-camp crossroads. Nor yet that Italian sunsets in oil should grace the smudgy sheet-iron sides of tipples. There are, however, beautifying touches that can be applied to coal-mine towns and to mines themselves—practical touches. The industry already has a few examples of beauty in mining towns. Trees and parks and flowers in such towns are recognized as exercising a wholesome effect upon labor relations between employer and employee, disturbed only by the influence of outside labor leaders and agitators.

But few indeed are the examples of beauty around the top works of the mine itself. Yet what sound argument can be brought against landscaping the property immediately around the tippie and power plant? A job of grading and sodding, a pleasing layout of shrubbery, a few trees, a cleaning up of discarded sheave wheels and broken cars, a coat of paint—and the place is transformed. City and town electric-light and pumping plants once were as blasting to their neighborhoods as the most slovenly coal-mine top works. A few hundred dollars expended in the “setting” has converted them. The same thing can be done at most mines.

But is there any need for it? Who cares what a coal mine looks like? Many of them are seen only by the miners and their families. The answer is that the effect upon those very people often is worth the expenditure. A Colorado mine superintendent of the hardest-headed, most practical type declares the proper lighting and whitewashing of the shaft bottom makes better workmen out of his miners. They instinctively get the idea the property is well managed, and that something of neatness and efficiency is expected of them in their

own work. A big Western coal company which once invested \$100,000 in architects' fees and extra building costs on a new property frankly to evade the excess-profits tax, found that the appearance of the property improved the performance of the workmen in that mine to such an extent that a permanent clean-up and beautifying program was adopted at all the other mines of the company for the entirely practical results to be attained. So there is something sane and sound in this talk of beautifying industry—even coal mines.

A Little Stone Dust—and Safety

IN COMMON estimation no mine is unsafe unless it has gas and has had an explosion. Coal dust looks as harmless as powder—and it is. It is remarkable with what confidence the man who knew the qualities of neither would view them both. They are both heavily fraught with mischief, but both look harmless enough. Strange also it is how proof and experience leave the average man blind to the dangers of coal dust. He is confident that what happened in Johnson's mine will never happen at his.

When something frightful does happen, when the women gather around the drift mouth or shaft and a hurried call goes over the wire for rescue men, he still declares that no one in reason would have expected anything like that at his mine. Meantime powdered coal, an explosive mixture, lay on the floor and the ribs of the mine. It looked harmless enough until it exploded.

And yet a little powdered shale dust on shelves, on the floor and ribs, or better yet in a stone-dust barrier would have prevented or at least shortened the travel of the blast. Such a simple remedy, that needs only occasional renewal, that is not like water cut off by freezing or the breaking of a pipe, and that does not fail because some underling overlooked some hazardous corner or misjudged the quantity to use; such a simple, readily installed remedy is passed over largely because it is so simple and unimpressive.

Rock dust has the advantage that it can be seen. No superintendent can fail to note if it is present. The use of it does not injure the roof, does not interfere with ventilation, does not involve a heavy charge for piping and pumping or for the maintenance of steam, does not becloud roadways or rot timber. It is useful in the West, where aridity and water scarcity make moistening prohibitively expensive. Yet in how few places is it used! Europe has ordered its application by law and regulation and has availed itself of it. But the United States still lags behind, despite all that has been done to inform the mining public of its value.

Unfortunate is it that the use of it has never been patented and put on the market. Rock dust is too cheap. We can all make it and use it. If it had only been commercialized and advertised, if permission to use it had been sold by traveling men and advocated by a corps of engineer salesmen, it would now be extensively used. As it is, it probably is utilized nowhere but at those mines where disaster has proved in some dire way that the coal dust at that mine is dangerous. Must we have explosions in every mine to make every operator realize that all the bituminous and lignite mines are dangerous and that a few of the semi-anthracite mines might be if the right opportunity were present?

Winter is coming. Surely now is the time to make sure that the mine which has never yet exploded never shall.

Safe Methods for Electric Mine Haulage That Insure Protection to Motorman and Equipment*

Maximum Grade for Locomotives—When and How to Repair Wheels
—Safety Features of Locomotive Design—Burn-outs Due to Defects
in Series Fields—Advantages of Good Feeders and Return Circuits

By J. F. MACWILLIAMS

Electrical Engineer, Pennsylvania Coal & Coke Corporation,
Cresson, Pa.

THE quantity of coal to be hauled per day, weight of the empty car, number of cars per trip, distance the loads have to be transported, track conditions and the grades to be traversed, all combine to govern the weight of the locomotive or the size of the hoist that must be used in mine haulage.

On a grade of 7 per cent a locomotive or loaded car will slide if once started downward; therefore hoists should be used instead of locomotives on grades of 7 per cent or over. This commends itself as a policy, for as a locomotive must haul itself as well as its trip up all grades encountered it becomes extremely inefficient on grades greater than 7 per cent.

As a trip will run readily on a $2\frac{1}{2}$ per cent down-grade, drags should always be provided to prevent run-aways in case of a coupling breaking where the grade is $2\frac{1}{2}$ per cent or over. Even if no one is injured, the wrecking of a single trip will prove far more expensive than providing a drag. Thus economy as well as safety will be promoted by its use.

As heavy rails give conditions favorable to traction and also support the load more safely and keep the track in better shape for a longer time, they should be used in preference to light rails.

RADIUS OF CURVES INFLUENCES MANY FACTORS

The wheelbase, diameter of the wheels, speed and other factors of a locomotive should be proportioned to the radius of the curves the locomotive is to run over. For instance, with a curve of 8-ft. radius, the wheelbase should be $20\frac{1}{2}$ in. and the diameter of the wheel should be 18 in. Similarly with a curve of 55 ft. radius, the wheelbase should be 10 ft. and the wheel 33 in. in diameter.

No less a tread than 3 in. should be used on a gathering locomotive running on 16- or 20-lb. rails, as the track cannot be kept in gage unless the tread is at least that specified. With a haulage locomotive, however, a $2\frac{3}{4}$ -in. tread will suffice if the tracks are kept in proper condition.

The minimum clearance of the lowest part of the locomotive from the cross rails should be $3\frac{1}{2}$ in., this allowance being increased to 5 in. at the bumpers; otherwise on a slight rocking of the locomotive or at changes of grades the bumpers will strike the rails and switches.

The weight on the drivers of a locomotive should be carefully balanced. Otherwise the locomotive will tend to climb the rails on curves, the drivers will be likely to slip, pinions and gears may be stripped, the brakes may fail to hold the load and the motors may burn out.

It would appear that the practice of connecting sets

of drivers by sprockets and chain so as to balance the load between the motors could be carried much further than is customary, with beneficial results. The braking effect on a steel wheel is greater and its tendency to slide is less than on a cast-iron wheel. For these reasons it is a safer wheel to operate, but care should be exercised in changing from cast-iron to steel wheels, as the motors are likely to be overloaded by the greater tractive effort after the change is made unless the speed is reduced in some manner.

The cast-iron wheel is cheaper in first cost and will wear less when first installed than the steel or steel-tired wheel, but as soon as the "chill" is worn through it must be scrapped. Due to the hardness of the tread of the chilled cast-iron wheel its adhesion to the rail is less than that of steel wheels. This reduces the drawbar pull as well as the power of the brakes. The steel wheel, whether rolled or cast, or the steel-tired wheel will give 25 per cent more tractive effort than the cast-iron wheel and if properly designed can be turned and trued up successfully several times, thereby offsetting the lower first cost of a wheel made of cast iron.

The most dependable form of brake is one which acts directly on the wheels. Brakes acting on the armature or intermediate shafts may be put out of service by the fracture of a shaft or the stripping of a pinion. For this reason regenerative braking with the motor should be regarded as merely auxiliary. When such braking is provided, the hand brake, which applies pressure directly to the wheels, by no means should be neglected. The brakes should be arranged so that the pressure against all the wheels will be equalized, for by that means the maximum braking effect will be attained.

In order to prevent overloading of the motors, which may cause the trip to get out of control when ascend-

WHEELS, AXLE AND GEAR

Care should always be taken to have the wheel tread and flange correctly shaped. Solid gears pressed and keyed to the shaft is becoming standard practice.

*Abstract of paper presented before Mining Section, National Safety Council, at its Buffalo meeting, Oct. 1-5.

Locomotive With Cable Reel

The equipment on the locomotive should be arranged to obtain proper balance. Minimum clearance should not be less than $3\frac{1}{2}$ in. Concentric cable with the negative on the outside renders the cable safer.

ing or descending grades, and because of the high cost of maintenance when the motors are overloaded they should be of such capacity that they can cause the wheels to slip before being overloaded.

One side of the motor should be suspended on springs to prevent shock to gears, pinions, axles and armature shafts. Many cases of high cost of maintenance may be traced to the poor condition of these springs or their elimination at the mine.

The axle linings and the housings of bearings should be carefully inspected for wear, for many armatures as well as many gears and pinions are destroyed from lack of proper adjustment of the gear centers and their alignment.

I prefer a bumper made of a steel channel with wood blocks having two inverted ells or climbing guards near the center. In a collision the wood acts as a cushion and the guards prevent the locomotive from being overridden by the cars. When the bumper is thus constructed the steel channel will bend or spring under severe impacts, whereas if the bumper is a casting it may be broken.

Wheels should be kept in good condition to prevent derailments. Many methods have been tried for overcoming the effects of wear, and the best means for maintaining safe wheels is a consideration closely allied to their efficient operation.

Steel tires, if shrunk on, will prove expensive to maintain unless a good mechanic is on hand to see that the tire is shrunk on the wheel in the correct manner. A tire that can be removed and installed like that on an automobile has been used with success by our company. We have a dummy center on which it can be readily installed for turning whenever the tire becomes worn. We tried for some time to true the wheels by grinding, but the cost was high and the mechanics made much objection to the dust raised during the truing operation. Furthermore, it is difficult to grind the wheels true by this method.

We have reduced the number of shapes and sizes of wheels on our locomotives to conform to certain standards and have so arranged them that in many cases after a wheel has been turned down a number of times it can be used on a locomotive taking a wheel of smaller diameter. Whenever a wheel has worn on the tread so as to have a false flange of $\frac{1}{4}$ in. deep it is sent to the shop for turning.

At the shops standard shapes are kept to which the flange and tread are turned to fit; all wheels are checked before the wheel is mounted on the axle to determine

if the bore and tread are at right angles. The wheels of any pair must be turned so that the diameters are within $\frac{3}{8}$ in. of being the same.

The wheels are gaged at the four quarters with a track gage, with ends shaped to the tread and made of $1\frac{1}{2} \times 1\frac{1}{2}$ -in. flat steel, the purpose being to determine if the axle and wheels are true. The wheels are checked again at the mines with a similar gage to determine whether they have been damaged in shipping. We have made no attempt to build up the whole tread of a worn or damaged wheel by welding for fear that doing so would warp the wheel or set up heat strains. However, flat spots in the tread not over 2 in. in length are sometimes restored by welding, the wheel being turned true after this operation.

We have not been successful in using self-grinding brake shoes, as every locomotive wheel would need a shoe suited to the deformity produced by wear and the wheel would have to be carefully watched. The shoe would have to be removed when it had done its work or it would wear down the tread excessively.

All the wheels should be turned at the same time, for if one pair has a thin flange and the other is new, derailments are likely to occur. In that event the locomotive will not ride parallel to the track. Consequently, when new wheels are installed a complete new set should be provided.

I believe it is safe to state that 20 per cent of the series fields in locomotive motors that have been oper-

STORAGE-BATTERY LOCOMOTIVE

Note the large protecting fuse and safety fuse box. The lip or climbing guard on the bumper to prevent the cars climbing on the locomotive can be faintly discerned.

ated over three years are defective, and it is good practice to test the fields whenever an armature is changed, otherwise the armature may burn out because an armature running in a defective field will tend to rotate faster than normal and if in parallel with another motor will carry an excessive load. It is for this reason principally that I believe it to be bad practice to provide only one circuit breaker or one fuse for a locomotive. Contrary to the general practice each individual motor should have its own protection.

If a thorough inspection were made of all locomotives it would be found that in many of them the wire is too small. In consequence time is lost on the road, material is destroyed, and the motorman unnecessarily exposed to danger. These defects could be avoided if more consideration were given to the size of the wire and its proper installation.

In most cases 4/0 trolley wire is as small as should be used in the trolley circuit and in some cases we are about to try 6/0 wire so as to obtain more power and give the trolley wheel a better contact. In but very few roadways should the hangers be placed over 25 ft. apart, and in many places they should be set even closer,

SPLIT MOTOR CASING

Many burn-outs and troubles with armatures are due to bad series field coils. A short-circuited coil will still pass current, but the reduced field strength causes the armature to become overloaded by taking more current for a given load.

as the price of a hanger and the cost of its installation is easily lost in the damage to pole heads, wheels, poles, etc. Furthermore, when the wheel leaves the trolley wire the motorman is exposed to many dangers due to flashes and the possibility of the trolley head catching something and being pulled off or becoming damaged.

Seldom are enough hangers installed on curves, and the trouble resulting from the incorrect alignment of the wire is so frequent that the motorman regards it as a condition altogether to be anticipated. The feed to the trolley wire from the feeder generally is mechanical and of insufficient capacity. Soldered feed ears with soldered lugs instead of setscrews and a soldered tap to the feeder would give better results.

It is remarkable to me that no one wishes to try out in the mines the Edison three-wire system, using the rail as a neutral. If the locomotive is in perfect condition, safety and economy are still lacking.

In many instances it will be found that a feeder having a cross-section of as much as a million circular mills has been installed, with 2/0 or 4/0 bonds on the rail and no return conductor. If the rail is of ample capacity it is more economical to bond the rail to its capacity than to go to the expense of a return conductor, as the labor cost of installing a small bond will be nearly as great as that for installing a large bond, and the material cost of the large bond will be much less than the cost of the small bond plus the return

MAIN AXLE BEARINGS

All bearings should be kept at a reasonably close fit to prevent excessive lash between the gear and pinion teeth. Hard metal end plates on the journal box prevent excessive end play of the driving axle.

conductor. I prefer the welded bond, for while the initial results obtained with the compressed type of bond are as good as those of the welded type, the welded bond unquestionably lasts longer.

Wherever possible feed ears should be of the soldered type, for after a clamp feed ear has been in service for a year its value is doubtful. To give the necessary strength the suspension ear should be long and thin rather than short and thick, so that the trolley wheel may pass over it smoothly and without vicious sparking.

With an inadequate feeder or return system the locomotives will work inefficiently, the cost of maintenance will be high and as the headlights will fluctuate, an irregular illumination of the track will make the haulage service dangerous. Furthermore, with bad trolley wire and hangers the vicious sparking that will inevitably occur will partly blind the motorman and distract his attention.

For main haulage hardly anything will compete with the trolley locomotive. If the excessive ventilation required by a gasoline locomotive can be provided for without undue cost that form of haulage can be used, but where such ventilation is costly or hard to obtain the gasoline locomotive cannot compete with the electric.

For gathering service, the storage-battery locomotive probably is the safest but it has the disadvantage that during the day's work it is constantly losing power. The cable-reel locomotive probably is the type most likely to cause accidents, for at the room neck the operative must make connections either with the trolley wire or with both the trolley wire and the rail. The dragging cable and cable reel also need care if accidents are to be avoided. We have found the duplex (trolley

FAN VENTILATED LOCOMOTIVE

The motors should be of sufficient capacity to spin the wheels before becoming overloaded. Overheating can be prevented in many cases by proper ventilation of the motors.

and battery) locomotive economical, as the battery has to handle only one or two cars in a room and the time lost in connecting a reel cable is obviated. The duplex locomotive is safer than the cable-reel type because the danger in the coupling of the cable is eliminated. We get more coal per locomotive with the duplex gathering locomotive than with either of the other types, the straight-battery machine gathering least coal of any.

All our cable reels are grounded through the frame of the locomotive and when using concentric cable some of the dangers may be avoided by making the outside copper always of negative or ground polarity.

The more nearly the proper amount of sand used the safer and more economical is the operation. The ideal quantity of sand to use would be such as would give

the rail a coating as thin as that placed on sand paper. A handful of sand will offer as much resistance as a 2-per cent adverse grade, and a large quantity will obstruct the trip after the locomotive has passed. It also will tend to reduce the power received by the locomotive and is likely to insulate it from the rail, making it dangerous for persons to touch the locomotive frame.

In conclusion I may say that we have had at our mines only one minor accident due to locomotives in three years and only three minor accidents due to electricity in that same period. In the past we had many derailments some of which were due to the springing of axles in the unloading of wheels. Since we have put our safety rules in force we have had no locomotive derailments for a whole year.

Open Cut to Head Off a Six-Acre Fire

AN UNDERGROUND fire in the Pittsburgh seam of coal near Charleroi, Pa., adjoining the workings of the Youghiogheny & Ohio Coal Co., of Cleveland, Ohio, bids fair to be extinguished after nearly a year of effort. All known means were tried, without success, to extinguish the fire, which covers about six acres.

Finally decision was made to cut off the fire by means of an open trench. This cut is approximately 1,000 ft. long. It has an average depth of 45 ft. at the ends, within 50 ft. of the outcrop, and the overburden runs up to 65 ft. at the center of the cut. The excavation when completed will have an average width of 65 ft. on the top of the cut and 25 to 30 ft. at the top of the coal. The material at the center of the cut lies in regular strata, approximately 15 ft. being yellow clay, 20 ft. hard shale, 12 ft. hard sandstone, 12 ft. hard slate, 3 ft. very hard sandstone and 3 ft. hard slate, the last being over the coal.

The material was drilled partly with jackhammers and partly with well drills but the greater part of the work was with the latter, 40-per cent dynamite being used. Cuts were made in low lifts, that being necessary largely because of cave-ins to old workings, for the excavation had to be made in ground undermined long ago, which accordingly afforded an uncertain support to the steam shovel. In fact only a shovel mounted on continuous treads could be used. Effective drilling

was difficult, because many holes went through to old workings, the location of which could not be determined in advance. Such holes were, of course, of no value for blasting purposes.

The contract for this work is being performed by the F. E. Welsh Contracting Co., Inc., of Cleveland, Ohio, and has been in progress since Feb. 10, in which time about 70 per cent of the total yardage of approximately 80,000 cu.yd. has been handled. The equipment consists of an Osgood one-yard continuous-tread revolving steam shovel, two four-car trains of 3-yd. cars and two 12-ton dinkies of 36-in. gage. Work is carried on in two shifts of nine hours each, and the material removed runs as high as 800 cu.yd. per day, the shovel often handling material that is too large to pass through the dipper. Large rocks are either chained to the dipper and loaded on the car or are cast back of the shovel to be jackhammered into sizes that the dipper can pass.

The upper 12 ft. of clay was cast over the sides, and the remainder hauled to waste at either end of the cut by the two dinky trains. The other 30 per cent of material is solid rock and hard slate, and progress is slow and difficult because of the cave-ins and by reason of the mine gas and gaseous fumes leaking through from the fire. Some of the material being loaded is too hot to handle with bare hands.

To date the work has been performed without accident, but the hazard is greater as excavation comes closer to the coal.

Digging Trench Across Fire

A cut 65 ft. deep is being excavated across the path of a mine fire despite escaping fumes and poisonous mine gases and in rock some of which is so hot that it burns the hands. The cut is about 1,000 ft. long, mostly in solid rock. The caterpillar mounting gives the shovel stability despite the uncertain footing.

Construction and Care of Distribution Transformers*

Selecting the Best Transformer for the Work—Consideration of Iron and Copper Losses—Building the Transformer—Careful Testing—Recommendations as to Proper Care

BY L. G. MASON

Engineer with Westinghouse Electric & Manufacturing Co.

THE use of distribution transformers in the mining field has an aspect somewhat different from their use in the distribution system of a central station supplying electric energy to light and power customers. In the case of a central station the entire income is derived from the sale of electrical energy to the power and lighting customers, and this revenue from the sale of electrical energy is directly contingent on the efficient operation of the generating and distribution system and the continuity of its power supply.

Where the revenue is derived from the sale of the product, as in a mine, the electrical machinery becomes merely an incident in the production, however essential it may be to the safe or continuous operation of the mining property. Its importance, however, is apparent from the serious effects a breakdown might cause in hazard to human life or loss of output from the mine through interference with regular production.

MINE OPERATIONS REQUIRE BEST EQUIPMENT

This brings up an important point. Has the mining industry always appreciated that only the highest quality of electrical apparatus is entitled to consideration for mining service? I believe that this is more generally true today than ever before, but looking back several years you can undoubtedly recall the time when you first decided to electrify certain parts of your system—competitive prices were obtained and in some cases the lowest bidder received the business irrespective of the better quality of higher-priced equipment. The actual comparison of the stability of the apparatus was not always appreciated and this undoubtedly was partly due to incomplete data on the characteristics of the apparatus. This to a certain extent prevented the selection of the most suitable material.

Today, however, conditions in this regard are vastly improved. Manufacturers have envisaged the opportunities for mining electrification, special equipment is developed for its service, and sales offices and branch service stations are testimony of the importance that this field of application of electricity is assuming.

This question of service may be considered from two standpoints: First, service delivered by the transformer when in operation, which is contingent on the quality of the apparatus; and second, service rendered by the manufacturer in assisting in maintaining service at all times through engineering help, through prompt shipment and through prompt handling of repair jobs.

Under the first classification we may consider the electrical performance of the transformer. Actual losses due to transformer operation may not show up on the books as a direct loss, but obviously a mine cannot avoid paying for the internal losses in its transmission and distribution system, so that a transformer

with better electrical performance possesses advantages over one with inferior performance.

Therefore price always should be secondary to quality, for the initial difference in investment will be recovered many times over in improved service.

In the consideration of the characteristics of a transformer essential to reasonable economy of operation, a relatively low iron loss is necessary as the iron loss is constant throughout the period the transformer is connected to the line, while the copper loss is a feature which is dependent on the load conditions. Low iron loss should not, however, be carried to the extreme with a consequent high copper loss, as the copper loss varies as the square of the load, and is, therefore, added to the peak load of the line. A high copper loss would necessitate a larger and more costly generating equipment; a kilowatt-hour of copper loss is, therefore, more expensive than a kilowatt-hour of iron loss. The average ratio of losses for a distribution transformer is approximately $2\frac{1}{2}$ watts of copper loss to one watt of iron loss.

The performance of a distribution transformer should not only take in the values of iron loss and copper loss but also should include the regulation at different power factors. This question of regulation becomes of great importance because it often is necessary to install a transformer at a point where the line drop becomes

FIG. 1—THREE DISTRIBUTING TRANSFORMERS

The relative size of 5, 15 and 50 kva. transformers is apparent here. Note the drain plug at the bottom of the 15 kva. transformer for draining oil for test purposes.

FIG. 2—HIGH-VOLTAGE TRANSFORMER COIL

Heavy micarta channel pieces are taped in position to insulate the winding from adjacent coils and iron.

very great. Under these circumstances, if the drop in the transformer is added to the drop in the line, the voltage may be reduced to a point where it causes unsatisfactory operation of motors and dim illumination of incandescent lamps.

Possibly this factor of regulation is not always given due consideration, but when it is understood that poor regulation means a large drop in voltage under full-load conditions it will be appreciated that just when normal voltage is required, such as during a heavy lighting load or during a heavy motor load, only low voltages are available, resulting, as stated, in the lights burning dim or the motors losing power and heating up.

So far we have dealt with certain major requirements that are essential in a transformer if it is to render good service while in operation; we will now review some of the features in the construction of a line of modern transformers that assure the requisite protection against breakdowns in service.

The construction of distribution transformers presents a far more difficult achievement than is commonly thought to be the case. The difficulty arises not in the actual transformation of a voltage from one value to another but is due to the ever-present desire to approximate a transformation with 100 per cent efficiency. The achievement of 100 per cent efficiency is as impossible as a perpetual-motion machine, but it is possible to reach very close to the 100-per-cent mark; in fact, transformers have been built having 99 per cent efficiency. Compare this with the efficiency of a steam engine or any other electrical apparatus and you will at once realize what care and pains have to be taken by the manufacturers in building this apparently simple piece of apparatus.

High efficiency of transformation is the goal toward which all manufacturers are striving, but this word

efficiency should not be taken only in its electrical sense. An efficient transformer must be one that is absolutely safe, reliable, and at the same time economical to operate. Keeping these three points in mind, the various details of transformer construction will show the very careful attention that is paid to even minor points.

A transformer comprises four essential parts: The iron core, the high- and low-voltage windings, the cooling medium (usually oil in distribution transformers), and the tank.

The method of assembling the coils and core will vary for different manufacturers and for different transformers, but, practically speaking, there are only two general forms of construction—the one being the core type and the other the shell type. In the core type the coils surround the iron, whereas in the shell type the iron forms a shell around the coils.

The same general methods of construction are used in both types and the same care is taken to render each type as efficient and economical as possible. In

FIG. 3—LOW-VOLTAGE TRANSFORMER COIL

This winding is wound on a mica-micarta barrier shaped to conform with the type laminations used.

order to obtain the greatest efficiency it has been found that no one type or form of construction is best suited for all sizes of transformers. For this reason the larger manufacturers use different forms of construction for different capacity ratings and voltage ratings. Distribution transformers may be subdivided into four types: The distributed-shell, rectangular-core, cruciform-core and simple-shell.

The distributed-shell has been found by our company

FIG. 4

Micarta Forms

These forms are shaped by machine while warm so as not to crack at the corners.

to be ideal for small-capacity, low-voltage transformers, and for a given weight of material it is possible to obtain lower losses and lower exciting currents than are obtainable by using a core-type construction. This form of construction, however, has its limitations, and because of the lack of cooling ducts and the difficulty in insulating it is not used on capacities larger than 50 kva. or on voltages over 4,600.

The rectangular-core type design is used on higher voltage and larger kva. ratings. On the very high voltage distribution transformers, such as 33,000, 44,000 and 66,000 volts, we use a cruciform core or circular coil design, and for the large kva. capacity distribution transformers, such as 150- and 200-kva., 25-cycle units, the simple-shell construction offers a convenient solution to obtain the necessary cooling, insulation and mechanical strength in as small a space as possible.

The same fundamental methods of assembly are included in all of the above transformers. The coils are wound separately on forms or mounds. The silicon steel laminations are later built in one at a time by hand.

In order to give a better picture of the care and attention paid in building distribution transformers, we will follow through step by step the various operations taken in building a 10-kv. steel-clad unit.

The windings of this type of transformer are built

FIG. 5—TRANSFORMER COILS COMPLETE

The coils consist of the high- and low-voltage windings ready for the test.

up of a number of separately wound high- and low-voltage coils; micamicarta barriers form the insulation between the high- and low-voltage windings. These barriers are formed by winding alternate layers of micarta paper coated with a shellac bond and built up with mica sheets on a steel mandrel under heat and pressure.

After winding, the tubes, which are circular in shape, are cut the proper lengths and then while hot are formed by means of expansion molds. Before being formed the tubes are heated to a temperature sufficiently high to soften the binder. This allows the flakes of mica to slide over one another at the corners and prevents cracking. Ideal insulating barriers are obtained by this method.

The low-voltage coils are wound separately on these micamicarta barriers. Micarta collars or fullerboard washers are placed at the edges of the coils to provide insulation and mechanical strength.

After winding, the coils are inspected separately and assembled into groups. Two low-voltage coils and one set of high-voltage coils comprise a complete winding. In the assembled group the high-voltage winding is placed between an inner and an outer low-voltage coil. This arrangement, while intended primarily to reduce the reactance and to improve the regulation of the transformer, also provides separation between the high-

FIG. 6—MAGNETIC CIRCUIT PARTLY ASSEMBLED

The silicon steel laminations are built into the coils and stacked by hand.

voltage winding and the magnetic circuit, and to a certain extent insulates the high-voltage winding from the ground.

The next step is a careful inspection and test of the windings to locate only defects or wrong connections.

The magnetic circuit, which is made up of thin sheets of non-aging silicon steel of a very high grade, is then built into the coil assembly, thus completing the core of this type transformer. The silicon steel used has a low hysteresis loss and conforms to the specifications of research engineers. Samples from each heat are given careful tests and only the highest grade of steel is selected for use in distribution transformers. The laminations are carefully annealed and given a coat of baked-on enamel to reduce eddy-current losses.

The core is now ready for a preliminary test, which is given all Westinghouse distribution transformers before impregnation. These preliminary tests are for the purpose of weeding out any transformers having losses exceeding their guarantees. Those transformers that pass the preliminary tests are then impregnated by the vacuum process, which consists of thoroughly drying out the transformers in ovens and then placing them in large vacuum tanks into which the impregnating compound is forced under high pressure after all the air has been removed from the tank.

The only step remaining is the final assembly of the transformer core into the tank and the final tests. The steel clad tanks used by the Westinghouse company comprise a tank built up by welding together a number of separate stampings. These parts are stamped out by large punches from blank sheets of Arneo rust-resisting iron. The tanks, after being welded together, are then subjected to a sand blasting process. This is done to render the surface more similar to a cast-iron surface and thus better able to hold the coats of paint. It is a well-known fact that a smooth sheet metal surface does not make as good a foundation for paint as a rougher surface, and in order to eliminate any possibility of the paint chipping off the outside of the cases the sandblasting process is used.

The next and final step in the building of a transformer is the testing process. This involves a very careful insulation test, also a test for ratio, polarity,

iron loss and exciting current. Those transformers that pass the limits allowed for these tests are then carefully crated and shipped to the ultimate user. Every transformer receives the same careful tests and the test results are always available for future reference.

The transformer, once it leaves the manufacturer, is often subject to a number of adverse conditions caused by lack of proper care and attention.

There is a wide difference of opinion among users as to the proper care to give distribution transformers. In general, distribution transformers receive very little

FIG. 7—FINISHED COIL UNIT

The winding and laminations are here shown before being mounted in the tank.

attention at the present time, but this is not an ideal situation and is caused chiefly by lack of man power on the part of the users and because the reliability of the modern transformers makes this possible without disastrous consequences. Periodic inspection, cleaning and testing would well repay its expense.

From a manufacturing point of view it is well known that a distribution transformer will have a much longer life when properly taken care of than when neglected. Detailed records are not always kept on transformers; therefore, there often is no way of determining the actual service various transformers render. The decisions as to the service various makes of transformers render, often are based merely on breakdowns, divided by the number of transformers on their lines. The results thus obtained do not give a correct picture of the conditions of operation, nor would they be entirely fair to all manufacturers.

In making the following recommendations as to the care of distribution transformers, we have taken into consideration the operating facilities of the average transformer user:

Transformers, when received from the manufacturers, should be stored in a dry room having an even temperature, and preferably the tanks should be filled

with oil. This latter precaution will to a large extent prevent moisture damaging the windings. A number of transformer manufacturers at the present time are impregnating their coils and iron as a unit. This tends to render the transformers more impervious to the absorption of moisture, as the impregnating compound effectually seals the windings, laminations and joints.

Before placing a transformer in operation, manufacturers' specifications recommend the drying out of the unit, but from an operating standpoint this drying-out process seldom is adhered to on distribution transformers, 13,000 volts and below, 100 kva. and less, as the users invariably feel that the factors of safety are sufficiently large so that even should there be a slight amount of moisture present, the insulation would be strong enough to withstand the abnormal conditions. The manufacturers, of course, disagree on this procedure, as they feel that every possible step should be taken to enable the transformer to render safe, reliable and economical service, and with moisture present in the windings safety and reliability are uncertain.

DRYING TRANSFORMER TO REDUCE HAZARDS

In those cases where a user desires to dry out a certain transformer, this may be accomplished in either of one or two ways, or by a combination of both. The usual method is to short-circuit one of the windings and supply sufficient voltage on the other winding to heat the transformer to a temperature slightly above the surrounding air temperature, but never above 80 deg. C. Under this heating process the transformers should be connected without oil in the tank, thus allowing the moisture to evaporate readily. The heating process should be continued from 8 to 24 hours, depending upon the size of the transformer. The second method is by the application of external heat, such as by building a fire in close proximity to the transformer and allowing the warm air to blow against the unit. Care should be taken to see that no sparks catch on the windings, which might char the insulation. The quickest way to dry out a transformer is by a combination of the two methods.

A few of the larger central stations at present are giving considerable thought to the care and maintenance of their distribution transformers already in operation, and one company has gone so far as to procure a truck on which is placed a De Laval oil purifying outfit, a complete insulation testing outfit, and a cleaning and repairing outfit. It is the intention of the company to visit every one of its transformers at least once every three to five years. The transformers in their turn will be removed from operation, cleaned and dried out, the oil will be purified and dried, the tanks will be painted, and any other necessary repairs will be made, after which the transformers will again be connected up for further operation.

This scheme seems to be a cheap method of keeping distribution transformers in continuous operation with few breakdowns and presents a far better method than that used heretofore in waiting until a transformer burns out and then bringing it back to a repair shop for repairs. It is, of course, impossible to foretell the savings that will result by the use of such a repair truck, but it is self-evident that the transformers receiving this care will be better able to withstand service conditions, and, furthermore, this truck service will enable the company to replace with larger units any

banks of transformers that may seem to be overloaded.

In so far as smaller companies are concerned, a truck of this nature would not be an economical proposition, but the underlying principles embodied in the use of this truck would apply, and it is recommended that every distribution transformer receive periodic inspection. Even a superficial inspection as to moisture and general conditions would be better than nothing. This can be effected very readily by removing the drain plug at the bottom of the transformer and drawing off any water that may be present. Any rusty spots on the tanks should be repainted and broken bushings should be replaced.

In case there is water present in the tanks immediate steps should be taken to have the oil drained off and replaced with dry oil, and in case the transformers in question have a primary voltage of above 6,600, then the transformers themselves should be dried out. The reason we make this distinction in voltage is that transformers 6,600 volts and below are suitable for star connection on 1.7 times the normal winding voltage, and, therefore, their factor of insulation safety is high. In fact, a number of companies have found that if tests are made, these lower voltage transformers do not show any marked tendency for breaking down even when a

certain amount of moisture is present in the windings.

A new development just brought out by several manufacturers consists of a temperature-indicating device to be installed in the tank of distribution transformers. These temperature indicators will give the average consumer a cheap and convenient method for determining the load conditions on his transformer. Some indicators have an advantage in that their use will enable the operator to pick out an underloaded as well as an overloaded transformer. In the former case the transformer should be replaced with a smaller size unit, saving considerable in transformer losses, whereas in the latter event the transformer should be replaced with a larger size unit, thus eliminating the possible chance of a breakdown with consequent delays and expense.

As time goes on there will be improvements that will render distribution transformers even more efficient and more trustworthy than at present, but in the meantime these suggestions will more than repay the owner of the transformer: The transformer coils and oil should be kept dry and clean, and the tanks should be kept free from rust. With these simple precautions and under normal load conditions distribution transformers should render efficient service for twenty-five to fifty years without replacing.

Cutting Cast Iron by Oxyacetylene Flame

AT ONE of the interesting Open Forum Sessions presided over by J. C. Wilson at the American Mining Congress, H. B. Rice, of the Oxyweld Acetylene Co., delivered an address on oxyacetylene welding which was followed by a discussion in which several questions which had presented themselves to A. J. Hendricks were answered by the author of the paper.

Mr. Hendricks referred to Mr. Rice's statement that only in the last two years had it been possible to cut cast iron with the acetylene torch. He wanted to know if the flame really cut it or melted it down; was it cut like steel as by a saw or was it cut in an uneven line? Mr. Rice replied that the cut was not clean like that made in steel and said that a little more acetylene was used in the cutting of cast iron than in severing steel by the same method. The cutting cannot be kept as well under control as can the cutting of steel, as the metal does not flow so readily. However, the operative can make within 50 per cent as good a cut with cast iron as with steel, but it takes a man with experience in the work to do as well as that. There is slag in gray iron and in consequence there is a tendency to clog. About 50 per cent more gas is used with cast iron than with steel.

The deepest cut he had ever seen made was about 14 in. The cast iron took more time to preheat. A welding torch is needed to remove the surface slag before working that surface with the tool. The hardening on the face of steel is only about $\frac{1}{8}$ in., but with cast iron it is deeper, and, consequently, whereas steel that has been cut with the oxyacetylene torch can readily be worked or welded, cast iron is too hard for working without previous use of the welding torch.

J. H. Edwards said that every mine should have welding equipment, but the first equipment to get was the oxyacetylene for cutting, but every mine should have electric welding equipment because of its greater economy and because with it the strains due to heating were not so severe.

W. P. Bovard, of the Ohio Brass Co., said that in some states it was unlawful to introduce gas into the mines, making it impossible to weld pipe underground. He added that light-weight electric welders can be used on large welds by progressive work. The carbon arc in the cutting of steel, said Mr. Bovard, melts the steel just as the oxyacetylene flame in the cutting of cast iron causes that metal to melt.

Canadian Institute Discusses Coal

At the fifth annual convention of the Southern Saskatchewan branch of the Canadian Mining and Metallurgical Institute, held at Estevan, Sask., on Oct. 3 and 4, coal mining formed the principal topic. Dr. Edgar Stanfield, of the research department of Alberta University, presented a paper showing the importance of a standard method of analyzing coal. Dr. J. A. Allen, of the University of Alberta, stressed the necessity of extensive geological research by the prairie provinces and outlined the plans for the provincial geological survey of the coal basins in Alberta with which the federal government was co-operating.

First aid to the injured was the subject dealt with by J. A. Kenny, who stated that the total number of accidents reported to the Workman's Compensation Board of Alberta for 1922 was 7,358 and gave a description of the training of classes for first aid to the injured. John Galloway, mine manager, and J. A. H. Church, mining engineer, of Edmonton, related their experiences in underground fires in coal mines. On the second day the delegates made an automobile trip to Columbus, N. D., and visited the lignite fields there as the guests of the operators. In the evening a banquet was held at Estevan at which the principal speaker was Premier Dunning, of Saskatchewan, who spoke in favor of continuing the lignite briquetting experiments. The results so far obtained would, he considered, warrant the carrying on of the work to a stage where it would be definitely established whether lignite can be briquetted on a commercial basis or otherwise.

IN VIEW OF THE SITUATION in the Ruhr it is difficult to understand how the expression "French leave" ever happened to be invented.—*Detroit News*.

New Equipment

Scraper Hoist Operated on Compressed Air

A SCRAPER hoist known as Model 300 Turbo Waughoist has recently been developed by the Denver Rock Drill Manufacturing Co., of Denver, Colo. This hoist operates on compressed air, which is always available in the mines wherever compressed-air rock drills are being used. The hoist is light in weight, well balanced and readily portable. It is very powerful for its size, developing a high starting torque, and is simple

WAUGHOIST IN SERVICE IN THE MINES

As a means of speeding up production scrapers are becoming very popular in many mines. They not only reduce the labor cost but aid greatly in increasing production.

and easy to operate. Safety devices prevent accidental operation and lubrication is practically automatic. High air pressures are not needed for successful operation of the hoist. The recommended air pressure is 50 lb. and with this pressure the average horsepower developed is 10. The maximum horsepower rating is 13.5. At a rope speed of 295 ft. per minute the hoist will develop a rope pull of 1,600 lb. At 118 ft. per minute

MODEL 300 TURBO WAUGHOIST

Compactness, ease of control and safety make possible the more general application of labor-saving devices to assist the miner. This little hoist operates by air.

it will develop a rope pull amounting to 2,200 lb.

This hoist weighs 495 lb. The transmission gears are placed at the end of the hoist opposite the air motor, thereby giving a good distribution of weight. The hoist, being well balanced, can be readily moved from one location to another without danger of damage.

The drum diameter is 6½ in. and gives the hoist the powerful starting torque so important in mining work. This more than compensates for the wear on the ropes that might occur from this small diameter.

The hoist engine is in reality an air turbine consisting of two steel rotors revolving within an airtight compartment. These rotors are carefully balanced and revolve freely, eliminating the vibration so common in other types of hoists. The construction permits no dead center; therefore the hoist will start in any position.

New Electric Solder Pot

A SOLDER pot with automatic heat control has been added to the line of labor-saving devices manufactured by J. D. Wallace & Co., 1401-17 West Jackson Boulevard, Chicago, Ill. This device greatly simplifies the problem of heating babbitt, white metal, wax and other materials which are slow conductors of heat. These materials must be kept at a uniform temperature if satisfactory results are to be obtained, and this new solder pot is designed to automatically maintain the temperature of the material in the pot at 600 deg. F.

The control of the heat is an adaptation of the principle used in the steam gage. A volatile substance which is very sensitive to heat actuates a Bourden tube which makes and breaks the electric circuit, thus controlling the temperature of the contents of the pot. The pot weighs only 13 lb. and will accommodate 15 lb. of solder, which can be heated in from 20 to 25 minutes.

ELECTRIC SOLDER POT WITH AUTOMATIC HEAT CONTROL

The proper temperature of the material being melted in the pot is maintained automatically; no need to spend half the time to do a job watching the melt heat up.

The pot operates on either 110-volt or 220-volt alternating or direct current. The heating element is a 900-watt heater, which is so designed as to apply heat to all parts of the sides and bottom of the container.

This equipment is a great saver of material and time. By properly maintaining the correct temperature, oxidation of the material in the pot is prevented.

*Preparing to Push a Long Trip of Mine Cars**

Safety Council's Mining Section Discusses Industry's Most Burning Question: Safety in Transportation

Large Increase in Membership and in Funds—Three Large Safety Conferences Promoted—Spirited Discussion of Value of Carbon Dioxide in Extinguishing Fire at Bitner Mine

RECORD attendance marked the Twelfth Annual Safety Congress of the National Safety Council held at the Statler Hotel, Buffalo, N. Y., Oct. 15. This was hardly surprising in view of the fact that the membership has increased from 3,060 to 3,321 during the fiscal year commencing July 31, 1922, an advance of 10.8 per cent. The number registering, however, showed an even greater advance, though this year the executive board required a \$2 registration fee from all outside the immediate vicinity of the convention city.

The receipts from the active membership totaled \$164,369.06; additional service, \$574.50; sales of pamphlets, bulletins and miscellaneous literature, \$16,015.14; the calendars, \$63,521.94 (gross revenue); the *National Safety News*, \$16,875.01, and interest earned \$289.23. The total revenue from all sources was over a quarter of a million dollars, or to be exact \$261,644.88.

Just before the last fiscal year ended the Council provided for the setting aside of a reserve of 7 per cent of all membership funds and that reserve is now \$12,629.18. In addition to this the surplus increased during 1922-1923 from \$34,819.78 to \$46,721.75, an addition of \$11,901.97. Thus the Council is \$25,000 to the good as the result of the year's financial operations.

In this substantial increase in surplus nothing can be ascribed to the publication of its *National Safety News*. It cost the Council \$11,502.67 more than it was able to earn. However, in estimating its balance no credit has been given to the dues of members allocated to that purpose, the members being assumed to receive it as a free service of the Council.

At the enthusiastic general session it was stated that the Council had added four new trade sections, two field secretaries, three new safety films and ten new community organizations. A. W. Whitney, speaking to the subject "The Inner Meaning of the Safety Movement, Particularly in Its Application to the Problem of Education," said that an accident etymologically and practically was the falling of something across the path of the normal, that our purpose was to build up the normal condition of life, which the very word "accident" signified was the condition being interfered with. Hence those who would teach safety should not preach a negative but actively urge the choice of the normal, the preference for the good adventure as opposed to that which was inherently bad.

Human nature had built up in the ages a spirit by which danger was circumvented and avoided almost without conscious resistance, but the development of machinery had created dangers against which there were no inherited defenses either mental or physical. The rule of the survival of the fittest might be written as the survival of the safe. In past ages those who were fitted physically and mentally to be safe survived. A new era with new dangers would have to find new resistances to meet new conditions.

L. A. De Blois, in his address on "The Year's Experience with Local Councils," incidentally struck a similar note. Power, said he, had extended from the factories and mines to the streets. It was now entering the homes. To some extent the factories and mines had met the dangers which power had created. Our industrial establishments, in proportion to the degree with which they utilized power, had been termed slaughter houses and shambles. Power, having moved to the streets as typified by automobiles, railroads and street cars had

*Motorman is about to push a long train of cars on to a tipple. Part of these are on an S vertical curve such as would favor derailment. The speed of pushing here, however, is so slow that if a wreck is caused it will not be severe. Boy is oiling the cars while opportunity presents.

turned these into shambles, danger increasing daily instead of decreasing, as in industry, and directing attention to these menaces instead of those of industrial establishments. Could it be that with the development of the home as a power user would come the time when the accident rate within the walls of dwellings would be our greatest concern?

That haulage accidents are in large degree preventable was the keynote of the meeting of the mining section of the National Safety Council commencing Tuesday, Oct. 2, and occupying each morning till Thursday, Oct. 4. The work and standards of the Pennsylvania Coal & Coke Corp. were described by G. F. MacWilliams, electrical engineer of the company, who was able to announce that, "we have had at our mines only one minor accident due to locomotives in three years" and "since we have put our rules in force we have had no locomotive derailments for a whole year."

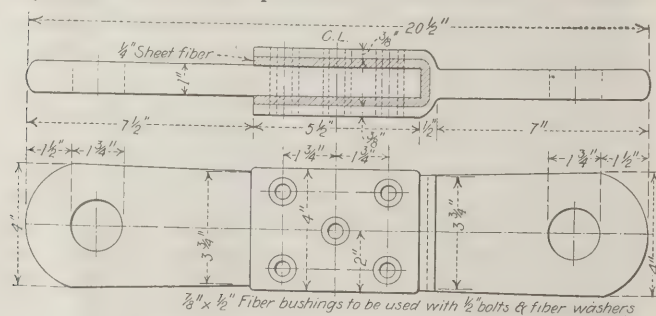

To measure what this declaration means it was necessary to call on Mr. MacWilliams for information as to the size of the company which had thus so greatly reduced accidents. He told those present that the Pennsylvania Coal & Coke Corp. operated thirty-nine mines and 205 locomotives and that in many places coal was hauled as many as five miles from the face to the tippie, the average haul in one mine being 3.8 miles.

In concluding his paper Mr. MacWilliams remarked that "too little attention is paid to fuses on all mine machinery; copper wire, pieces of iron, etc., often replacing fuses. Circuit breakers are jumped or blocked, with the result that the equipment is overheated, insulation is roasted and in consequence in case of short-circuits or other troubles neither machine nor operator has any protection.

"All kinds of mine cars are used, yet, as far as I can learn, little consideration has been given to reducing the friction in plain bearings by properly proportioning them to the speed of the wheels, except possibly in the case of the hollow axle.

"Most couplings are of primitive type and a source of danger. The car in general is seldom designed so that it will haul the largest quantity of coal with the least possible dead weight, due regard having been given to the kind of mine in which it is to be used."

Mr. MacWilliams advocated using a gage to determine at the mine as also at the shop whether the wheels were at right angles to the axle, careful balancing of the weight on the drivers of a locomotive, the turning down of wheels as soon as the false flange is $\frac{1}{4}$ in. deep and the turning of any two wheels of a pair till they are within $\frac{3}{8}$ in. of the same diameter. The care manifested is justified by the results, which are altogether beyond reasonable expectation. Mr. MacWilliams said

INSULATED DRAWBAR COUPLING

This coupling is used at the mines of the Pennsylvania Coal & Coke Corporation for preventing current from running back from the locomotive to the mine cars. Fiber serves as the insulating medium.

that finding 16-lb. rail too light for rooms, they are laying the track in all new rooms with 25-lb. steel.

In a discussion of means whereby current can be prevented from traveling back through the cars, Mr. MacWilliams advocated the use of fiber as the insulating medium. He said that wood tended to split and that fiber gave better results. He offered to provide an illustration of the coupling for use in the transactions. This line drawing appears herewith.

FORMING CONFERENCES, MOST FEASIBLE ACTIVITY

The meetings opened with the Presidential address and the report of C. Lorimer Colburn, whose work since the middle of the year has not been financed in any way by the Council. He is now specifically assigned to the work of forming chapters of the Joseph A. Holmes Safety Association and while he can and is requested by the Bureau of Mines to co-operate with the National Safety Council the work must not be allowed to interfere with his other duties. Consequently he is not able to give that work any more than incidental attention.

In the first year Mr. Colburn visited 78 mines and in the second year, believing that better work could be accomplished by forming conferences which would meet to promote safety, he visited only 49 mines. Mr. Colburn declared that four separate inspections were or could be accorded at any mine—the mine's own inspectors, the state mine inspectors, the insurance inspectors and those of the Bureau of Mines, for the Bureau will inspect a mine if desired. In consequence the single safety engineer of the Council could hardly hope to compete with all these agencies for inspection. Forming conferences, therefore, seemed a more rapid way of promoting safety work.

Byron D. Shove then read his paper "Safety in Underground Transportation—Metal Mines," which clearly reveals how different the problems are in such mines where the grades are made to suit haulage and not to accord with the irregular floor of a coal bed. In metal mines the difficulties are largely connected with overhanging chutes and the trolley wire. At the Gogebic mines of the United States Steel Corporation automatic gongs of the gravity type are placed on all electric locomotives. The gong sounds only when the locomotive is in motion. Mr. Shove remarks, "We feel that any such warning should be automatic so as to remove the personal equation which is always present in hand-operated warning devices. Headlights are placed on both ends of the locomotive and are protected by meshed screen guards placed in front of the open face. A red light is carried on the rear end of the train. After many tests we are using a railroad flagman's lantern manufactured by Adams & Westlake Co., Chicago, Ill. It is similar to a railroad switch light, but much smaller and lighter. It has two red bull's-eyes which are in line with each other. The lamp in the lantern burns signal oil.

"In years past we have had serious accidents to motormen whose feet, hanging outside the locomotive pit, were crushed between the locomotive and the cars or timber trucks it was moving. We have, therefore, made it imperative that the motorman shall, when the locomotive is in motion, keep his feet inside the locomotive pit. As the locomotive goes out to the shaft, the trolley passes over a spring contact switch. This throws on red lights in the drifts and crosscuts [cross and main

entries] from which other locomotives are pulling. When the locomotive returns from the shaft the contact spring switch is automatically thrown by the trolley again but in the opposite direction. This extinguishes the red lights and turns on the green ones, showing that the block is clear.

ONE WHEEL TIGHT AND THE OTHER LOOSE

"Where a drift [cross entry] breaks off a crosscut [main entry] the radius of the curve usually is 30 ft. The axles of the mine cars are $2\frac{1}{2}$ in. in diameter and of cold-rolled polished steel. They are equipped with 16-in. semi-steel wheels, one of which is pressed on to the axle, the other being loose. This loose wheel takes up the slippage when the car is going around a curve. The couplings are of cast steel and the links and pins of wrought iron. The gage of the cars is 24 inches."

These quotations from Mr. Shove's paper are not arranged exactly in the order in which he placed them, but they are grouped in such a way as to furnish the coal-mining engineer with the information likely to interest him. The loose and the tight wheel, though made more necessary by the sharp curves, would have its advantage when turning into the rooms of a coal mine where the car has a larger gage and the wheels, therefore, more slippage. The lights switched on and off by the trolley are interesting, but they would have to be used in a different manner in a coal mine because usually the distance to the shaft or tippie is greater than on a metal-mine level. The "crosscuts" from the seam to the landing of the level usually are quite short except at considerable depths.

Joseph Reed, safety engineer, Consolidation Coal Co., said that the automatic couplers would become uncoupled at track joints if they were of the Junior type, the pins not being long enough to prevent that action. Another engineer said that he had been obliged to weld shoulders on the coupling, above and below, so as to give the required depth. Later discussion called attention to the difficulty with automatic couplings where cars were pulled over a sharp knuckle, as at the tippie.

In discussing A. F. Brosky's paper "Safety in Underground Transportation in Coal Mines—Tracks," Mr. Reed said that he had found that in a mine where 50- or 60-lb. rail was used and where naturally false flanges wore in the wheels to accord with such rail, the locomotive had little tractive effort on any relatively short or newly installed length of 70-lb. rail because the wheels rested on a surface only about $\frac{1}{4}$ in. wide.

B. F. Tillson said he had used 70- to 80-lb. rail in slope shafts and had obtained a section with extra deep webs so that the rail was practically a girder. The rail rested on piers 10 ft. apart. The skip is hauled at the rate of 4,000 ft. per minute. Mr. MacWilliams said that no little trouble was caused in mines by not using the "suspended joint," which probably is universal practice in railroad work. Such a joint makes travel much easier.

At the second session R. H. Seip read A. F. Hoskin's article entitled "Safety in Underground Transportation in the Coal Mines of Illinois with Special Reference to Derailments." Mr. Hoskin's recommendation that cars be given a longer wheelbase so as to make them more stable did not meet with Mr. Reed's approval. He said that if the wheelbase were made longer, the radius of

WHEEL AND TIRE GAGES USED BY MR. MACWILLIAMS
The Pennsylvania Coal and Coke Corporation is confident that by keeping the axle true and the tread at right angles derailments can be avoided.

the curves into the crosscuts that are driven through the pillars for the recovery of pillar coal would have to be increased and that would make the work of "pillaring" more dangerous. We need flexibility in haulage as much as stability, for with sharp turns the roof is more easily sustained.

It would not improve matters if we saved lives in haulage, only to lose more or even as many in pillar drawing. R. Dawson Hall explained that in Illinois pillars were not drawn and in other sections the pillar was worked entirely off the end, the car standing on the straight room track and the coal being shoveled from a distance to and into the car making a car of longer wheelbase than that now being used permissible. B. F. Tillson said that perhaps scraper loading would fill the requirement and that it might be necessary to make a radical change of that sort to permit a longer wheelbase and afford the needed safety.

LEAVING THE WORK TO THE LOCOMOTIVE BRAKE

The article by G. M. Gillette, general manager, and Joseph W. Reed, safety director, of the Consolidation Coal Co., entitled "Safety in Underground Transportation at Coal Mines—Mine Cars," not only brought up the much discussed question of brakes and no brakes but added the question, "Should neither brakes nor sprags be used on cars?" The opinion of Frank Haas was quoted to the effect that with modern haulage the locomotive was sufficiently fitted with brakes to control a car effectually. Mr. Reed said that it often was necessary for men to move cars by hand as, for instance, before firing a shot. A shot fired when the car was near the face might severely shatter the end. It might be necessary to move a car at the end of the shift for fear that it might be buried under a fall during the night or on an idle day following.

A sprag might serve especially with a block to hold the car, but where brakes have once taken the place of sprags it is hard to find good spraggers, for spragging is one of the decadent fine arts. The relative safety of the end and side brake was discussed, and Mr. Reed said they had only one mine with end brakes. It might not be significant, but the men preferred them and the accidents were fewer. He agreed with Mr. Hall that they seemed the more dangerous even though the snapper barely went between the cars at all in putting on the brake.

One of the coal men present said that he used the end brake, the lever of which was pulled toward the brakeman, and he found it safer than the side brake. The men at his mine were not allowed to push the brake over. Mr. Illsley, of the Bureau of Mines, brought up the question of clean track, but it was suggested that as most of the spragging or braking was done at certain specific places and as the operation causes collisions between the braked portion of the trip and the free-running part it was almost impossible to keep such places clear of fallen coal even with daily cleaning.

Mr. Reed said that at least 75 per cent of the braking occurred at such places.

Following this paper Mr. Gillette's "Safety Practices Pamphlet" entitled "Maintaining Safety Interest" was briefly introduced by Mr. Colburn, and John T. Ryan, president of the Mine Safety Appliances Co., showed how with a tube of Hopcalite a mouse can be protected from the carbon monoxide in the air with which it is furnished. By passing the air with its 1 per cent of carbon monoxide the mouse was soon overcome and being supplied with an atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide was soon revived. Experiments also were made into the Bureau of Mines method of matching with a scale of permanent colors the product of a mixture of blood saturated at different carbon-monoxide concentrations, diluted with water and mixed with pyrogallie and tannic acids.

DEADENING A MINE FIRE WITH CARBON DIOXIDE

By far the most interesting of the sessions was the third and last, at which Charles L. Jones, of the Mellon Institute of Industrial Research, Pittsburgh, Pa., gave his paper on "Fighting Mine Fires by Carbon Dioxide in Liquid Form." It was expected that from this would arise the question as to the availability of carbon dioxide for fighting metal-mine fires, but that possibility was not for a moment brought up. William G. Duncan, of Pennsylvania State College, was present and he took a diametrically opposite view of the situation to that taken by Mr. Jones.

The facts from the contributions of the two opposing parties appear to be as follows: The Bitner mine fire was fought at first by the use of water, without any great progress being made. The season had been extremely dry and water was quite scarce, and all that could be obtained was what was not being used by the coke ovens. This was entirely insufficient for the necessities of the occasion. The official in charge at the mine was Patrick Mullen, a man of recognized ability and long experience, but neither is of much avail without a plentiful supply of water, as any city fireman will tell you.

SHALLOW COVER GREATLY AIDED WATER SCARCITY

Now, Bitner mine had a shallow cover, and many falls had occurred which had broken the surface in such a degree as to permit the entrance of air. In consequence the dry or sealing method did not offer any promising solution. The situation was indeed desperate, and there are many mines which under like circumstances have been allowed to burn for years, in the hope—a vain one in all instances—that the fire would burn itself out. The company wanted to operate the Bitner mine and feared the extension of the fire to others of its valuable properties. In consequence it was decided to use carbon dioxide to save the mine, and the fire speedily decreased in severity, so much so, in fact, that the company decided to reopen the mine.

This was done with much caution. Hot coals were found, and some places where fire was still found to be active were re-sealed so that time would cause the fire to go out. These later were opened and the fire extinguished with water. At the places where the water had reached to the roof the fire was completely extinguished. Many other places which the water had not reached had traces of extinguished fire but no fire or hot coals present. Some places probably had never been the seat of fire, and some others were still so hot that unsealing caused them to blaze.

Every evidence points to the fact that the use of carbon dioxide had a most valuable retarding and extinguishing effect. It doubtless prevented vacua being formed during the cooling process. It is at such times that carbon dioxide has its utmost value, for if a neutral gas is not supplied the fire will find a way to replenish its vacuum and will draw air through walls, ribs and roof rocks, obtaining enough not only to fill up the vacuum but to stimulate combustion. In fact the carbon dioxide is more needed with a cooling than an active fire, for the fiercely burning coal will make its own extinctive atmosphere and its own outward pressures that will preclude the infiltration of air.

After the cessation of the use of carbon dioxide, the fire may cool further and again obtain air. The pressures may not indicate much suction, for if the cooling is slow the air may come in slowly, but in sufficient quantity, nevertheless, to rekindle the fire. As the fire recovers, the suction becomes less, for there is then no reduction in volume. Consequently the administration of carbon dioxide should be continued until unsealing, enough being used to prevent the formation of even a partial vacuum.

It appears that some heated coal still remained in the mine after its reopening. In the time that has elapsed since March 19, 1923 it is not strange that a fire had developed, so that even now, nine men are employed steadily playing water on it with six lines of hose, with about thirty cleaning up slate which fell during the period when the fire was still burning, the work being necessary to restore the haulage roads and put the mine in condition for further operation.

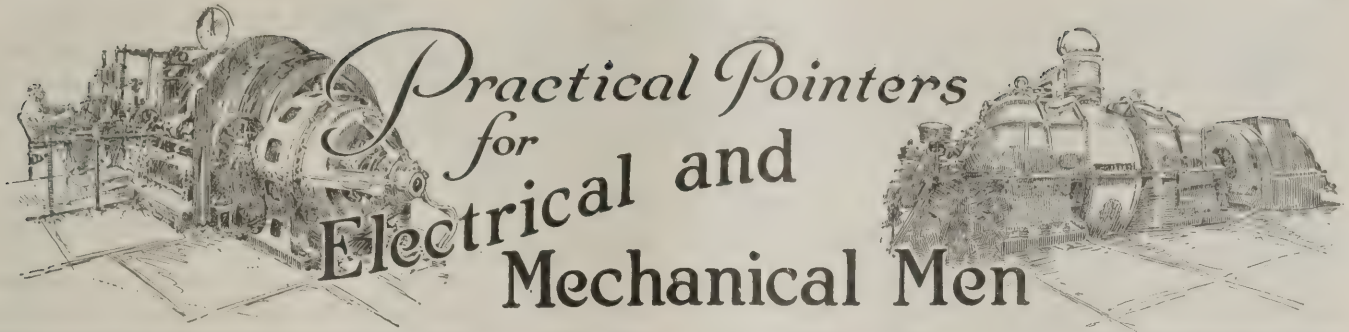

QUESTIONS HOW MUCH AREA FIRE HAD COVERED

Mr. Duncan declared that there were two original fires and that they were separated by a length of 1,200 ft. of unburned coal. He held that the reason why no fire was found in much of the so-called fire area was because it had never been on fire. Mr. Jones said that the fire may have started at several places, but that the main haulageway showed signs of fire throughout the distance between these points.

In the course of his remarks Mr. Jones said that in no place where the air analysis showed continuously for a month less than 5 per cent of oxygen was any sign of fire or hot coals found after unsealing. Mr. Tillson remarked his surprise at this in view of the fact that he had fed a producer working on carbonaceous shale with an atmosphere having only 5 per cent of oxygen and nevertheless maintained rapid combustion. Mr. Jones said that Mr. Tillson was feeding the producer with a good current of air, even though that air was lacking in oxygen. Other conditions also were different.

Mr. Colburn earlier in this session, which commenced an hour before the scheduled time and terminated an hour later than provided, read extensively from the Safety Practices Pamphlet, "Maintaining Safety Interest." A report was made on the specific services of the Mining Section based on inquiries made by the chairman. The articles on "Maintaining Safety Interest" from George C. Hewitt, supervisor of industrial insurance and hospital service, Pacific Coast Coal Co., Seattle, Wash.; Thomas Cowperthwaite and Albert Tallon will be printed in the minutes and duly considered in the final draft of the Safe Practices Pamphlet.

The names of the newly elected officers of the section and of the Council will be found in the Oct. 11 issue of *Coal Age*, page 566.

Coal-Handling Towers Made Portable By Use of Wooden Rollers

BECAUSE of the large shipments of coal and coke coming into San Francisco by steamer, the State Harbor Board has just finished placing six large wooden rollers under each coal tower, so that the towers can be easily and quickly moved to points on the dock convenient to the ship's hatch.

The coal is unloaded from the hold of the steamer into these towers, which is then loaded into trucks or wagons by means of chutes, each tower having two chutes. The towers will soon be equipped with a third chute, by means of which coal or coke can be loaded directly from the tower to a car, as there is a railroad spur paralleling the towers.

Before placing the rollers under the towers it re-

long, with a 10-in. groove in the center. There is an iron bar bearing for each roller which slides on an iron-shod timber, which in turn is bolted to the timbers supporting the tower. A large iron washer placed between two timbers and properly greased, gives a swivel motion, enabling the rollers to be turned at any angle, permitting the towers to be moved in any desired direction along the dock.

CHARLES W. GEIGER.

Brushes for Mine Locomotives

SELECTING the proper grade of carbon brush for an electric machine always is a difficult problem. To obtain the right brush requires a thorough knowledge of the various grades of carbon, backed up by long experience in service. Even with this information the problem is still difficult because loads, qualities of materials in the commutators, vibration, etc., vary greatly even with the same type of machine.

When making a selection of a brush the following fundamentals in connection with operating conditions should be considered: Commutation, life of commutator, life of brushes, frequency of inspection, current density.

The above factors will vary more or less with the design of the motor, the design of the brushholder, the correct spacing of the brushes, vibration, condition of the equipment, condition of the armature bearing, condition of the commutator surface, brush tension, load, speed, service conditions, etc.

Since all of these factors must be taken into consideration, the best and most reliable results are obtained by making tests of recommended grades in service under actual operating conditions. Brush manufacturers generally are willing to assist the operator in making service tests. The following general information regarding brushes will help the operating man more intelligently to select brushes for service tests.

Carbon is a non-metallic element found in both crystalline (made of crystals) and amorphous (non-crystalline or irregular shaped) form. Natural graphite is carbon in a crystalline form, and is mined in many localities. Amorphous or non-crystalline carbon may be obtained in the form of coke or lamp black. Artificial graphite is obtained by heating amorphous or non-crystalline carbon, such as coke, in an electric furnace to change its structure to a crystalline state.

By the use of the above materials the following general classes of brushes are made:

- (1) Carbon brushes—made of crushed coke and binder.
- (2) Graphitized brushes—made of carbon and then electrographitized.
- (3) Graphite brushes—natural graphite and binder.
- (4) Metal graphite brushes—natural graphite with metal powder and binder.

With the modern commutating-pole locomotive motor

LARGE COAL TOWERS MOVED WITH WOODEN ROLLERS

By means of the rollers shown at the base of the towers it is possible to locate any tower in a new position in a short time. These rollers and plates can be turned so as to move the tower in any desired direction.

quired a crew of six men, with two hydraulic jacks and rollers and a motor truck, to move one of the towers. With this equipment it required about two hours to move a tower only a few feet on the dock. Now by means of the rollers placed under the towers any tower may be moved to any new position in five minutes by the ship's tackle.

Each of the rollers is 8 in. in diameter and 3 ft. 6 in.

having commutators undercut, and considering costs per locomotive mile, brush end wear, side wear, breakage, life, commutation, life and maintenance of commutator, etc., these classes of brushes are best suited for locomotive motor service as follows: (1) Graphitized brushes—best all-around results. (2) Carbon brushes—next best all-around results. (3) Graphite brushes—very special and limited uses. (4) Metal graphite brushes—not used at all.

In the process of manufacture the most important operations, depending upon the class of brush being manufactured, are as follows:

- (1) Crushing, carbonizing (if it is done) and cooling.
- (2) Milling, mixing, cooling and remilling.
- (3) Moulding and packing in the furnace.
- (4) Gas baking.
- (5) Electric baking or graphitizing.

The two most common general methods of manufacture are:

Extruded or Squirted.—Where the material in the form of pulp is forced through a metal die under pressure and then cut off to the desired length and baked with a high temperature to carbonize the bond and permanently set the material. This method is used in making the cheaper grades of carbons, which do not have much strength to resist breaking and chipping in service.

Moulded and Machined.—Where the material is moulded into blocks under heavy pressure and baked. The brushes are cut from these blocks and machined to exact size. This method is used in making the high-grade brushes and gives a brush of uniform texture and strength that is best suited for locomotive work.

In the manufacture of various grades of carbon brushes best suited to meet the requirements of operating conditions, the following characteristics of the brush must be considered: Contact drop, hardness, resistance, coefficient of friction, apparent density, abrasiveness, heat conducting, conductivity, toughness.

Length.—For use in the more modern brushholders, the brush should be not over 2 in. long; that is, when new they should not extend above the top of the brush box for the following reasons:

- (1) If longer, they are subjected to a greater side pressure due to the action of the contact tip, which increases the side wear, tends to bind the brush in the box and reduces the direct pressure on the surface of the commutator.
- (2) If longer, they are discarded because of excessive side wear before the added length can be used up in end wear.
- (3) Approximately the same mileage can be secured from the shorter carbon; and hence, since the brushes are bought on a cubic-inch basis, the first cost is less.

The width is not so important; they can have as much as $\frac{1}{8}$ in. clearance in the box without causing any trouble in service.

Thickness is very important, as the initial clearance between brush and brush box should be approximately from 0.006 to 0.008-in. If it is much less the brush will tend to stick in the box and bind, and if greater, it will soon rattle in the box, wearing away the side; it also will tend to chip and break, thus reducing the life of the brush.

When pigtailed were used on brushes, it was considered necessary to copper-plate the brush to provide a good electrical contact for the shunt connection. With the

present design of brushholder having a heavy braided copper shunt from contact tip to brush box, shunted brushes have been discontinued, so the copper plating is unnecessary; in fact, it is objectionable on the higher grades of brushes as it tends to peel off in service and bind the brush in the box.

For locomotive work, pigtailed or shunts on brushes have been practically done away with on account of the following reasons:

(1) First cost—they were used with the cheaper grades of brushes which had a comparatively short life, making renewal of brushes at frequent intervals necessary.

(2) Inspection—the pit men could not be depended upon to maintain shunts during inspection.

(3) Not very reliable—the design was such that shunts became loose, disconnected and were not reliable.

With these conditions greatly improved by the use of a higher grade of brushes with longer life, requiring less frequent inspection, and by improved methods of fastening pigtailed to brushes some advantages can be obtained by their use. In certain specific cases, especially for very heavy current densities, they have been adopted with a saving in maintenance. Foreign practice tends to the more extensive use of shunts than is customary in this country.

Determining Power Transmitted Through Leather Belt Drives

WE HAVE a large fan at one of our mines which has not yet been called upon to develop its ultimate capacity. From time to time we have increased its output to meet our air requirements, but now I believe we have reached the safety limit on the belt. This belt is a double leather one and I would like to know how much power we can safely transmit through it.

SUBSCRIBER.

There are several important factors which determine the amount of power transmitted by a belt. These may be resolved to total effective pull and speed of the belt. The effective pull is the difference between the tension on the tight and loose sides of the belt.

Expressed as a formula, this equation becomes—

$$\text{Horsepower} = \frac{L \times S}{33,000}$$

L = Total effective pull in pounds.

S = Speed of belt in feet per minute.

This effective pull usually is expressed as working tension per inch of belt width and depends upon the grade of material, thickness, and also upon the speed of pulley due to the centrifugal force which tends to throw the belt away from the pulley surface.

Allowing ample factors of safety and taking into account the effect of centrifugal force, average values for effective tension per inch of width for single leather belts are shown in the following table:

Belt Speed Feet Per Minute	Working Tension Pounds Per Inch Of Width
1,000	72
2,000	68
3,000	65
4,000	60
5,000	53
6,000	45

The above values are for 180 deg. arc of contact. For double belts multiply the figures in the table by 1.6 and for triple belts multiply by 2.

Problems of Operating Men

James T. Beard

Rules vs. Experience in Regard to Post Timbering

Rules Enforced of More Value Than a World of Experience—Penalty Makes Rules Effective—Systematic Timbering Surest Safeguard

WRITING on the subject of "Posting the Face of the Coal in Driving Rooms," *Coal Age*, Aug. 2, p. 181, George Edwards has enunciated a principle worthy of the most careful consideration. I agree with him that it forms the underlying foundation in mine timbering and as such should be heeded earnestly by every miner.

Nothing can express more forcibly the truth conveyed in the writer's own words, "One post promptly and properly set is a greater safeguard than a world of experience in the mining of coal." Judging from what others have said, on this subject, I believe their experience is in accord with my own conviction that it is far better to enforce strict rules and regulations, in regard to timbering, than to leave the matter to the whim of the miner, notwithstanding his experience.

The practice of miners in regard to when and where they should set timbers to make their places safe for work has clearly demonstrated the unreliability of dependence on their judgment. This is shown by the fact that numerous coal-mining companies have found it necessary to establish timber rules and, in many cases, severe penalties are imposed for any violation of the rules.

PENALTY FOR VIOLATION OF RULES INSURES RESULTS

Even where the rules are strictly enforced, results show that they are of little value, unless each rule carries a suitable penalty for its violation. Many experienced miners become so inured and hardened to danger that they are prone to take wholly unnecessary chances on their lives, in the effort to finish loading a car before setting a post.

It has been my experience that even when an experienced miner uses care and judgment to insure his own safety he cannot always tell when he is in imminent danger from bad-roof conditions. In one district with which I am familiar, the miners are troubled with what they call "blind rolls," that are more like the well-known "pot bottoms" in other localities.

In that district, many of the companies have made stringent rules in respect to the setting of timbers at the working face. The formation overlying the coal is such that the roof slate will give practically no indication of weakness when a stone, from 10 to 20 ft., in diameter, and anywhere from 2 to 6 ft., in thickness, will drop from the roof without warning. Previous to the establishment of the rules, many experienced and inexperienced miners were killed.

When timber rules have once been posted the experienced miner has no argument that he can offer the mine foreman as an excuse for not having timbered his place according to the rules. The foreman is saved much annoyance and embarrassment caused by the persistence of experienced cranks, who protest against doing what they consider unnecessary work in the timbering of their places. The foreman has only to refer them to the rules.

Mr. Edwards has mentioned the supposed difficulty in reference to setting face timbers in machine mining. In Alabama, this is no problem at all. Practically all of our mines have timber rules that are strictly enforced. Each miner sets his props according to rules, without reference to the machine.

ALABAMA LAW FOR MACHINE RUNNERS

The Alabama State Mining Law requires a machine runner to replace all props removed by him in cutting the coal. This does not, as some may suppose, impose a hardship on machinemen. In the instance cited by Mr. Edwards, the claim of the machine runner and the mine foreman, that they must have 14 ft. between the face of the coal and the timbers is wholly false. Such a clearance is quite unnecessary when the work is properly managed.

It is well known that, with continuous coal-cutting machines, after sumping the cutterbar a clearance of only 6 or 7 ft. is required for the machine to pass the timbers, in moving along the face of the coal. A scheme that is often adopted, here, is to let the motor and gear housing lag a little behind the cutterbar. In other words, the machine is kept at a slight angle with the face of the coal.

TIMBERS REMOVED AND RESET AS MACHINE PASSES

In one instance, to my knowledge, the timber rules call for a distance of 4 ft. between the first row of props and the face of the coal. All props are set 4 ft. apart, in every direction. The rooms are 35 ft. wide, and two tracks are laid in each room. The machine enters, say on the left-hand track. At the face, one prop is taken out to allow the machine to be swung around ready for moving across the face. The 4-ft. space, between the first row of props and the coal, is ample for that purpose.

Then, before pulling the machine across the face, the prop on the left is replaced. On reaching the other side of the room, a prop on that side is removed to permit the machine to be again swung around ready for sumping. The cutting then proceeds until the machine reaches the second prop, which is removed after the first prop has been replaced. In this manner, the machine proceeds to cut the coal, each prop in turn being removed and reset as the machine passes.

Finally, on reaching the left-hand side of the room, the machine is withdrawn from the coal and reloaded

ready to be moved to the next place. Under this system, when the miner starts to shoot his place every prop is standing a maximum distance of 4 ft. from the face of the coal. Any props that may be knocked out by the shots are promptly reset, before the work of loading the coal is commenced.

Inasmuch as the props are now quite a distance from the solid coal, the miner is required to load his coal along the entire face, to permit another row of props to be stood, and this must be done before the remaining coal is loaded. A casual examination of the roof in this mine would not seem to demand that these precautions are necessary.

However, systematic timbering is the surest safeguard and this plan was adopted after the occurrence of many accidents proved it to be unwise to depend on the judgment of the miners in making their places safe. The good results obtained have proved the wisdom of the plan.

JOHN WALLS, SR.

Ensley, Ala.

Working Three Continuous Seams of Coal

Many things considered in choice of best method of working—Numerous advantages in longwall method—Value of coal and relative costs of handling waste material the determining factors.

THE discussion following the inquiry that appeared in *Coal Age* some time since, regarding the best method of working three seams of coal separated by thick partings of shale and slate, has interested me greatly. I quite agree with James Gray, whose letter appeared in the issue of Sept. 13, p. 403, regarding his choice of the longwall method of working these seams.

Without inspecting a field and studying the conditions as they exist, it is difficult to arrive at a correct conclusion regarding the best and most profitable method of working any coal seam. There are always many different items to be considered and to disregard any one of these may result in failure. The success of the proposition depends primarily on a thorough knowledge of the situation, in any given case.

In the past, I have conducted operations in the mining of coal seams where the partings would vary from 6 in. to 9 ft., in thickness, making the conditions encountered similar to those described in this inquiry. My experience has convinced me that there is no system of working better adapted to the working of such coal than the longwall method of mining. One strong argument in its favor is that there is no deadwork required, such as is necessary in room-and-pillar work.

ADVANTAGES OF LONGWALL METHOD

The practical advantages presented by the longwall method are numerous. Not only does it lessen the cost of production and afford a larger output from a comparatively small area, giving a greater concentration of work, but there results a more complete extraction of the coal, less explosives are required and less trackage, with a reduced cost of upkeep, and the ventilation of the mine is more easily effected.

From the information given it is not clear whether it is desired, or advisable, to remove the 12 in. of bottom coal, which would involve the handling of the large amount of waste material forming the lower parting. This question can only be determined by the value of the coal and the relative cost of handling the slate parting, which is from 18 to 24 in. thick.

As suggested by Mr. Gray, in order to gain height on the roadways, the lower parting and the bottom coal may be lifted for that purpose, provided the coal is hard enough to resist being crushed by the weight coming on the pillars, as the face is advanced. My preference would be to take down the upper parting to the top coal, using this waste material for building the necessary packwalls to maintain the roads. There will then be less danger of loading dirty coal when taking down the upper seam in retreating.

In planning the work by the longwall method, the slant roads must be laid out so as to cut off the rooms at not too great a depth or length. These slant roads are driven on an angle of 45 deg. with the main road. As each slant road cuts off the rooms, the work of taking down the top coal is started at that point and conducted on the retreating plan.

It is not necessary to wait until the rooms driven in the middle seam have reached their limit, or the boundary line. It is important, however, when that is done to leave sufficient pillars in the top seam to protect the roadways in the seam below.

Taking everything into consideration, I believe the better plan would be to push the work in the middle seam to the boundary, before attempting to extract the top coal on the retreating plan. Then, when retreating use can be made of the same roadways in the middle seam, by building simple inexpensive chutes for loading the top coal into the cars standing on the track below. Wherever practicable, the use of conveyors at the coal face will greatly reduce the cost of production, by requiring a less number of roadways to be kept open and reducing to a minimum the building of the necessary packwalls.

COAL INSPECTOR.

McKeesport, Pa.

Marsaut Type of Safety Lamp

Thousands of this type of lamp in use—Important to know in what respect the lamp is weak or unsafe—What experiments have shown regarding the possibilities of failure.

AMONG the letters that have been contributed regarding the various aspects of the explosion that occurred in the Wakesiah coal mine, Nanaimo, B. C., Nov. 24, 1922, all but one writer assigned the cause of the explosion to the failure of the Wolf-Marsaut, bonneted safety lamp carried by the fireboss.

At the time, the fireboss had almost completed his inspection of the mine, previous to allowing the day-shift to enter for work. Owing to this fact, there were but 13 men at work in the mine. All of these escaped, except two—the pumpman who was standing on the main slope and was killed by flying coal blown from a trip of cars near him, and the unfortunate fireboss whose act was the primary cause of the explosion.

Inasmuch as there are, today, thousands of lamps of the Marsaut type in use in the mines of this country and on the Continent, the question of the safety of the lamp, under all conditions that may arise in coal-mining practice, is one of absorbing interest. Unfortunately, in this case, a certain mystery surrounds the occurrence, in respect to both the conditions and use of the lamp claimed to have failed.

One uncertain feature is the lack of knowing the exact conditions to which the lamp was exposed. From

all accounts, it appears that it was not in the hands of the fireboss and under his control at the supreme moment. While it is said that the fireboss was not seriously burned, his death being due to suffocation in the afterdamp of the explosion, we are told in the report of the disaster that the man's cap was badly burned.

Now, if we assume that the fireboss used his cap in an attempt to smother the flame of the gas burning within the lamp, we must admit that the man himself would have been badly burned. Or, had the cap been on his head, its being burned would point to a similar condition of the man's body.

In view of these conflicting aspects, we are left to surmise only as to the actual manner in which the lamp was handled, or as to what took place at the fatal moment. Evidently, a few seconds elapsed between the fireboss losing his cap close to the lamp, and his reaching the place where his body was found, at a distance of 84 ft. from the lamp.

What is of prime importance, in this matter, is to ascertain the actual conditions that surrounded the lamp. All the witnesses agree that much finely powdered coal dust was present and became a factor in the initiation of the explosion. That the lamp was surrounded by an atmosphere highly charged with fine dust is only natural to assume; but what seems remarkable and, to my mind, quite impossible is the statement that the interior of the lamp gauzes showed signs of being intensely heated, while the outside of the wires gave no such evidence.

WEAK POINT IN THE MARSAUT CONSTRUCTION

To my knowledge, experiments have proved that the safety of lamps of the Marsaut type is seriously reduced by the presence of fine coal dust in the ventilating current; but I know of no experiment having been made, with firedamp burning in a lamp surrounded by a dust-charged atmosphere, when the lamp did not fail.

My conclusion is that such a condition forms the most plausible explanation of this disaster. In the same connection, it is interesting to recall that the eminent French mining engineer, the inventor of the lamp that bears his name, discovered where the peculiar weakness lay in this type of construction. Marsaut found that when the lamp was raised vertically into a quiescent atmosphere of pure or nearly pure methane, so that the sharp gas entered and filled the top of the lamp, the result was an explosion took place within the chimney of sufficient force to drive the flame through the gauze and ignite the gas outside. This has been proved by experiment; and there are a few instances on record showing the failure of this type of lamp under such conditions.

The original Marsaut pattern had no air ring to admit the air below the wick flame, which is one of the features of the Wolf lamp of the Marsaut type. Although this feature adds to the lighting value of the lamp, in my opinion, it has a tendency to reduce the safety value of the lamp and render it less sensitive to the detection of gas. Seeing that this lamp is now used in Vancouver Island coal mines, exclusively for testing purposes by firebosses and not for the purpose of giving them light, I would suggest that there would be an advantage if the air holes admitting the air below the wick flame, were closed, or did not exist, which would make the lamp conform to the original pattern of the bonneted Marsaut safety lamp.

JAMES ASHWORTH,
Mining Engineer.

Cowley, Alberta.

Inquiries Of General Interest

Mechanical Every-Day Problems In Mining Practice

Kinetic Energy of Moving Trip of Cars—
Size of Ventilating Fan and Engine Re-
quired for a Given Circulation in Mine

IN CONNECTION with duties that have fallen to my lot as mine engineer, I have been delving much recently into the intricacies of mechanics, much of which I have found beyond my comprehension and ability to understand and apply, in the practical solution of problems that arise in the mine. *Coal Age* has been a great help to me, in more ways than one, and I want to ask for its assistance in working out two problems that have given me trouble.

First, what is the kinetic energy of a moving trip of six cars, each weighing when loaded 3,500 lb. I want to estimate on a speed of hauling at four miles per hour and compare this with the energy that would be developed should this trip break loose and descend an incline or slope at an estimated speed of 15 miles per hour.

The second problem is to find the size of the fan and engine required for the circulation of an air current of 160,000 cu.ft. per min., against a water gage of 3 in., assuming the fan is direct-connected or belt-driven and running at a speed of 120 r.p.m., taking the steam pressure at the throttle as 120 lb. per sq.in. and supposing the engine cuts off steam at one-third stroke. I want to estimate on a piston speed of 300 ft. per min. If this fan is operated by an electric motor what current will be required at a pressure of, say 500 volts?

Michel, B. C., Canada.

MINE ENGINEER.

Regarding the first question, the kinetic energy of a moving body is the energy it possesses by virtue of its mass and velocity and is expressed by the formula $\frac{1}{2}mv^2$. It is measured by the work given out by the body in bringing it to rest and is expressed in foot-pounds. Calling the weight of a body w , its mass m , the height through which it falls h , and the force of gravity g , we have, for the kinetic energy developed at any given velocity v , since $m = w/g$ and $v^2 = 2gh$

$$\frac{mv^2}{2} = \frac{w}{2g} (2gh) = wh$$

The weight of a trip of six cars weighing 3,500 lb. each, is $6 \times 3,500 = 21,000$ lb. For a speed of 4 mi. per hr., the velocity of the trip is $4 \times 5,280/60 = 352$ ft. per min., or 5.83 ft. per sec. Then since $g = 32.16$ ft. per sec.,

$$\text{Kinetic energy} = \frac{21,000}{2 \times 32.16} (5.83)^2 = 11,237 \text{ ft.-lb.}$$

Again, for a speed of 15 mi. per hr., or $(15 \times 5,280) \div (60 \times 60) = 22$ ft. per sec., the kinetic energy is $(21,000 \times 22^2) \div 64.32 = 158,022$ ft.-lb.

In determining the dimensions of a fan for any required circulation, it is first necessary to estimate the

potential factor of the circulation, as expressed by the ratio of the quantity of air passing, to the square root of the pressure in the fan drift. Thus, to pass 160,000 cu.ft. per min., against a 3-in. gage, this potential factor is $X = 160,000/\sqrt{5.2 \times 3} = 40,510$.

The outer diameter (D) of a fan required to circulate a quantity of air (Q), against a potential factor (X), at a speed of n revolutions per minute, may be found by the formula

$$D = 467 \frac{Q}{Xn} = \frac{467 \times 160,000}{40,510 \times 120} = 15.37 \text{ ft.}$$

The same result may be reached in another way. For example, general fan practice has shown that the best results are obtained when the fan is capable of producing a theoretical water gage that is 40 per cent in excess of the gage required in the fan drift. Or, calling the theoretical water gage I , we have in this case $I = 1.40 \times 3 = 4.2$ in. On this basis, the outer diameter of a fan capable of producing a theoretical water gage $I = 4.2$ in., at a speed $n = 120$ r.p.m. is

$$D = 900 \frac{\sqrt{I}}{n} = \frac{900 \sqrt{4.2}}{120} = 15.37 \text{ ft.}$$

Assuming an efficiency of the steam engine driving the fan as, say 85 per cent, the required indicated horsepower of the engines is

$$H = \frac{160,000 \times 5.2 \times 3}{0.85 \times 33,000} = 89, \text{ say } 90 \text{ hp.}$$

Then, taking the steam pressure at the throttle as 120 lb. per sq.in., the engine cutting off steam at one-third stroke, gives for the mean effective pressure in the cylinder,

$$0.9[0.743(120 + 14.7) - 17] = \text{say } 75 \text{ lb. per sq.in.}$$

Finally, estimating on a development of 90 hp. in a single cylinder, a mean effective pressure of 75 lb. per sq.in. and a piston speed of 300 ft. per min., gives for the diameter (d) of the steam cylinder

$$d = \sqrt{\frac{33,000 \times 90}{0.7854 \times 75 \times 300}} = 12.96, \text{ say } 13 \text{ in.}$$

For direct connection or belt-drive, the fan making 120 r.p.m. and the engine 240 strokes per minute, the length of stroke is $300/240 = 1.25$ ft., or 15 in., which makes the required size of the engine 13x15 in.

To develop 90 hp. electrically, under 500 volts pressure, will require a current of $(746 \times 90) \div 500 = \text{say } 135$ amp.

Examination Questions Answered

Examination for Mine Foremen, Olympia, Wash., Aug. 1, 1923

(Selected 1st-Class Questions)

QUESTION—*Explain the constant 5.2, used in connection with water-gage calculations.*

ANSWER—The constant 5.2 represents the pressure per square foot due to a water column 1 in. in height. Since the weight of 1 cu.ft. of water is 62.5 lb., the weight of a layer of water covering 1 sq.ft. of surface and 1 in. in depth is $62.5 \div 12 = 5.2$ lb. The pressure exerted on any given surface being measured by the depth of the water and the surface pressed, 1 in. of water column always represents a pressure of 5.2 lb. per sq.ft.

QUESTION—*State what systems of ventilation you are familiar with. Give the advantages and disadvantages of each.*

ANSWER—The two common systems of ventilation are known as the "blowing" and the "exhaust system," respectively. In the blowing system the air is forced into the mine under a pressure greater than that of the atmosphere, by means of a fan or other device capable of creating a pressure. The particular advantage of the blowing system is that any gas generated in the roof or overlying strata, or accumulated in abandoned areas, is forced back and often escapes through fissures reaching to the surface. If the system has any disadvantage, it lies in the fact that in case of a breakdown of the fan the resulting drop in pressure will be accompanied by an increased outflow of gas from the strata and abandoned places.

In the exhaust system of ventilation, the mine is

ventilated under a pressure less than that of the atmosphere. This is accomplished by connecting the fan drift with the intake opening of the ventilator. The action of the fan then creates a depression in the fan drift, and the atmospheric pressure on the intake opening of the mine forces the air into the mine against that depression. The advantage, in the application of the exhaust system, is that the hoisting shaft and main haulage road are the downcast and intake airway, respectively, which keeps them free from gas.

The exhaust system is particularly adapted to the ventilation of a gassy mine. In either system, however, it is assumed that the fan is installed at a separate air shaft, which becomes the downcast shaft in the blowing system but is an upcast shaft in the exhaust system of ventilation. The disadvantage of the exhaust system lies in the fact that, the mine being ventilated under a pressure less than that of the atmosphere, there is a tendency for any gas generated in the adjoining strata, or accumulated in abandoned areas, to flow into the mine workings. Again, the movement of the loaded cars passing out of the mine offers an increased obstruction to the intake current and, to that extent, increases the mine resistance and the power required for ventilation. Also, all the dust of the main haulage road is carried into the workings.

QUESTION—*How would you retimber a gangway that had caved, if three sets of timber were broken down and the case liable to run?*

ANSWER—This condition requires extra precaution being taken to avoid accidents. After a careful examination of the timbers and before disturbing the old sets, temporary timbers should be stood to guard against the fall of the loose material when the broken timbers are removed. It may be possible to stand new sets of timbers between the old ones, as permanent timbers. When this has been done one of the old timber sets should be carefully removed, taking care to avoid the men being caught by a possible fall of the loose slate above. As one old set is removed a new set of timbers should be inserted in its place. In this manner, the work should proceed, taking down one set at a time and standing new timbers in their places.

U. S. Coal Commission Arraigns Jobbers in Report on Distribution; Suggests Regulation in Emergency

Wholesalers' Margins Said to Have Risen 200 Per Cent from Pre-War Figures—Too Many Handlers and Pyramiding During Shortages Blamed for High Prices—Retailers Dealt with Gently

Wholesale dealers in coal during recent years have been exacting profits in some instances 200 per cent above their earnings in pre-war years, according to the report of the U. S. Coal Commission on the wholesale and retail coal trade, made public Oct. 21. The retail coal dealer is practically exonerated of responsibility for high prices. The report, which relates to both anthracite and bituminous coal, is a bulky one, comprising about 50,000 words, with numerous tables covering margins, expenses, profits, investments and tonnage handled.

Among the causes of the high price of fuel, the commission says that it found an unnecessary duplication of service with too many handlers in the industry between the mine and the retailer. Coal was sold from wholesaler to wholesaler before it ever reached the retailer. Sometimes this reselling would take place twice or three times. The maximum number of resales discovered was four.

The Commission attacked this extravagance in the industry in its recommendations to President Coolidge and Congress that the government be given power to regulate the distribution of fuel in times of shortage.

Dealing with ninety wholesalers who made reports, the Commission finds that profits have mounted each year. In this connection the report says:

"The showing made for the trade as a whole for the entire United States is that with a total profit of 3.6c. in 1913, the ninety concerns reporting made a return on total capital of 19 per cent, and on net proprietor's equity, after paying interest on borrowed money, 24.1 per cent, and, in 1922, the 424 wholesalers reporting with a total profit of 7.3c. per ton, made returns of 21.8 per cent on total investment, and 25.6 per cent on proprietor's equity.

"In 1917 with a profit of 10.9c., the 182 firms reporting made 45.4 per cent on total investment and 54.8 per cent on proprietor's equity. In 1920, the banner year, the 333 wholesalers covered, with a net profit of 15c. per ton, realized 55.2 per cent on total investment, and 66.6 per cent on net proprietor's equity. In every year except 1921 the return on total investment was greater than 15 per cent and that on proprietor's equity was greater than 18 per cent."

TOO MANY WHOLESALERS IN ANTHRACITE TRADE

The Commission concludes that in the anthracite trade there are too many wholesalers. "The explanation of this undue attraction of new capital to the trade," it says, "is to be found in the high profits on investment realized in the business."

Discussing gross margins and profit per ton and on investment the report has this to say:

"The years 1917 and 1920 were the years of highest margins and profits per ton in all groups. The large profits per ton were reflected in high earnings on investment in those years for all groups. The year 1921, although a year of relatively high margins, was a year of depression in the wholesale trade in all groups; expenses were high and profits were low. One group in 1921 showed a small loss of 2c. per ton on coal handled, but other income changed this loss into a small gain. In this year the rates of earnings shown by the different groups were the lowest shown for the ten-year period.

"In general, the earnings of the ten-year period were large for all groups. Rates of return on total investment of 40 per cent or more were made by every group in one or more years. The lowest rate was 1.5 per cent by the anthracite-less-than-50-per-cent group in 1921.

"With the one exception of the dull year 1921, the total investment would be returned in profit, at the rates shown,

in periods ranging from about one and two-thirds to eight years for the different groups, with from two and one-half to four years or five years as the period most often required. On net proprietor's equity, representing what the owners have in the business, the rates of return were greater, and the periods required to return the total proprietor's equity correspondingly less. Here again 1921 was, of course, the poorest year for all groups."

In summarizing its findings in regard to wholesalers the commission makes these observations:

"Although the independent wholesaler occupies a necessary place in the distribution machinery for coal, the nature of the business is such as to make possible undesirable speculative activities on the part of wholesalers in times of shortage. Coal, both for industrial and household purposes, is a prime public necessity. Recurring shortages, with their periods of wild speculation, tend to attract too much capital into the wholesale trade. The result is more wholesalers than are necessary to conduct the business. In times of shortage, speculative buying and selling among the excessive number of concerns results in great duplication of function and enhanced prices to the consumer.

ANTHRACITE MAKES FERTILE FIELD FOR SPECULATOR

"Anthracite, because it is a limited natural resource, the demand for which in recent years has pressed closely upon production at all times, with limited possibility of substitution of any other fuel equally satisfactory for household use, occupies the position of a necessity of life in many communities habituated to its use and therefore yields readily to the speculative activities of the wholesaler.

"The Commission's study indicates that there are altogether too many wholesalers, but that, notwithstanding this fact, the wholesale trade has made large profits in most of the ten-year period from 1913 to 1922, inclusive, and excessive profits in the panic years 1917 and 1920. The year 1922 generally showed more moderate and even small earnings, due to curtailment of tonnage on account of the strike.

"The Commission's study also indicates that in times of shortage the pyramiding of wholesale margins through the speculative activities of wholesalers results in the enhancement of prices, without furnishing the public an equivalent in distribution service.

"Recurring periods of shortage with wild wholesale speculation point to the need of a public service viewpoint respecting the entire coal trade, backed by legislation providing for strict regulatory powers, on the part of the federal government over the entire production and interstate distribution of coal in order that American industries and households shall at all times be assured of continuous and adequate supply of coal at reasonable prices. The exercise of such regulation is especially good in times of shortage and wildly fluctuating prices.

"When real competition for the purchaser's tonnage exists, such competition is probably the cheapest and most efficient regulator of wholesale margins, but in times of shortage it fails entirely. It may therefore be desirable to set up skeleton regulative machinery which shall be put into operation when, and only when, in the judgment of the President an emergency exists, thus limiting active regulation to periods of national emergency.

URGES LIMITATION OF PROFITS

"The power to regulate should include the power to limit, to a definite maximum amount per ton, the margins that may be taken by one or more wholesalers between the mine and the retailer or consumer, thus limiting speculative

wholesaling. The maximum amount of margin should be the same whether taken by one or by two or more wholesalers.

"The experience and practice of the Federal Fuel Administration along this line furnishes basic information of great value, both as to method and workability of such regulation. All regulatory powers should be backed by adequate penalties for violation of regulations promulgated by the government or its regulatory agency, with necessary outlining of court jurisdiction for their enforcement in cases of violations and of review in cases of aggrievements arising out of regulations promulgated.

"Regulation of wholesale margins to a definite maximum amount per ton would go far toward eliminating the abuse of the reconsignment privilege by which unscrupulous wholesalers, after selling a car of coal to one retailer or consumer, finally sell it to some other who will pay a higher price for it.

"Greater publicity should be given to the inter-relations of nominally independent wholesalers and operators through interlocking stock ownership and officers. Such information should be in the hands of the government agency charged with the duty of regulation of both the production and distribution of coal, to serve as a basis for intelligent decision as to whether a given wholesaler is entitled to pose as independent of the operators from whom coal is purchased.

"In the case of anthracite coal, the Commission's inquiry indicates that during the past year the passing of coal through the hands of wholesalers, with arrangements to split commissions back to the operator, was used by some operators as a means of obtaining higher prices on interstate commerce shipments than those approved by the Fair Practices Committee of the Pennsylvania Fuel Commission."

MUCH CRITICISM OF RETAILERS UNJUST

Dealing with the retail coal trade, after stating that the retail trade presents problems distinctly its own, and mentioning the frequent great public dissatisfaction with the prices charged and the general conduct of the business, the Commission says:

"In some cases such criticism is undoubtedly well founded, but in others it is based on lack of knowledge on the part of the public that the causes of the high prices and shortages of coal felt by the consumer are beyond the control of the retailer. Frequently, public opinion is unjustly aroused against the retailer by inflammatory newspaper articles. On the whole it would seem that what is needed is a better understanding of the trade and its problems on the part of those whom it serves, and more discriminating criticism.

"Recent high prices have encouraged co-operative buying experiments and municipal coal yards as attempts to cut the costs of fuel to the consumer. This is a part of the general trend of public opinion toward a public service viewpoint regarding the production and distribution of coal. The organized retail trade generally opposes such experiments, as they jeopardize the position of the established retailer wherever they are successful. Such movements should be given a fair trial to demonstrate whether they can furnish the same service to the public at a less cost than the estab-

lished retailer. If they can do so they will survive. If they cannot the established retailer will survive as the most efficient method of retail distribution.

"The results of the Commission's inquiries regarding the retail trade indicate that it is generally conducted on a competitive basis. Prices and margins have increased sharply in all sections of the country since 1918. Expenses, also, especially in the last two years, have increased so that net profits per ton and on investments have shown a tendency to decrease.

"During the five-year period, 1918 to 1922, the average rates of profit of retail dealers throughout the country have generally been moderate, and much less than those of wholesalers. In some sections of the country they have been small, while in others they have been fairly large. For the country as a whole, the earnings of 273 identical companies ranged from 11.6 per cent to approximately 23 per cent on total investment, and from 12 to 25 per cent on owner's investment in different years.

"The effect of premium anthracite coal on the retail trade is to make direct business connection with one or more of the big companies which do not sell their product at premium prices of prime importance to a successful retailer. In fact, such direct connection has, during recent years, been more important than real efficiency in retailing in determining what retailers in the anthracite territory will be able to stay in the business. So long as such conditions continue, competition based on real efficiency of retailing can have but little effect in eliminating the really inefficient dealer from the trade.

"The forcing of small sizes upon the retailer by both operators and wholesalers is a practice that works hardship upon the retailer whose trade is not equipped to absorb steam sizes.

"In general, the competitive nature of the retail trade makes regulation of margins and prices unnecessary, except in cases of emergency shortage. In case such emergency regulation is necessary, it should be a part of a fully co-ordinated scheme of regulation covering the production, wholesale distribution and retail distribution of coal.

"In case price regulation is attempted, it, in fairness to the retailer and the public, should take the form of regulation of margins, other than the fixing of definite prices. Such regulation of margin permits the setting of different maximum margins to cover different types of trade, and different amounts of service rendered by city and country dealers.

"This Commission is firmly of the opinion that the solution of the problem of extortionate charge for retail coal, where it exists, is largely in the hands of the communities themselves and that where the public is alert to its rights and ready to apply the remedy no such problem will exist."

THE ADVISORY COMMITTEE which is being set up to co-operate with the coal division of the Department of Commerce will be composed of fifteen members. Three members will represent each of the following branches of the industry; bituminous operators, anthracite operators; wholesalers, retailers and transportation. The personnel of the committee has not been determined as yet.

Trade Commission Charges Conspiracy to Enhance Anthracite Prices

As a result of an inquiry, instituted at the direction of President Coolidge, into alleged unfair practices in the anthracite business the Federal Trade Commission has filed a complaint against the operating firm of Madeira, Hill & Co., of Philadelphia, and the following wholesalers: Pattison & Bowns, of New York; the Titan Fuel Corporation, of New York; Hartwell & Lester, Inc., of New York and Massachusetts; Clement P. Brodhead, of New York, and Lynn M. Rainger, of Boston.

The Trade Commission alleges that Madeira, Hill & Co. exacted a rebate from wholesalers varying from 50c. to \$2.50 per ton. The defendants have been summoned to appear before the Commission Nov. 19, when a hearing will be held on the charges.

Charles E. Lester, president of Hartwell & Lester, Inc., in a letter to *Coal Age*, says: "We have not, subsequent to Oct. 23, 1922, the date mentioned by the Commission, purchased from Madeira, Hill & Co. any of either of the two sizes of anthracite referred to, with the exception of four cars of washery chestnut, which were both purchased and resold by us at a price less than \$10.50 per gross ton at the mines. We have never entered into any secret understandings or agreements, such as charged by the Federal Trade Commission, either directly or indirectly, with Madeira, Hill & Co., nor have we ever rebated, refunded or paid in any manner, either directly or indirectly, any moneys in excess of the price at which coal was purchased and orders confirmed by us."

C. P. Brodhead, president of the firm which bears his name, said: "We have never been a party to any secret rebates, nor have we been engaged in any conspiracy, nor have we ever adopted illegitimate methods in our business."

Gardner Pattison, of Pattison & Browns, characterized the Trade Commission's investigation as "a fishing expedition." "In common with other prominent coal firms," he said, "we have always conducted our business in a perfectly open-handed manner. I shall be very pleased to meet any charges which the commission lays before me, and I am quite certain that after representations have been made at Washington these absurd complaints will be dropped."

The Titan Fuel Corporation "denies that they ever entered into any secret condition, understanding or agreement, in writing or verbally, either directly or indirectly, with Madeira, Hill & Co. to rebate or refund to them directly or indirectly, any part of the margin or profit realized over and above the price the coal was purchased for."

Special Government Prosecutors Major David A. L'Esperance and Rush Williamson, who at the direction of Colonel William Hayward, United States Attorney at New York, are conducting an investigation into the matter of the alleged scarcity and high price of anthracite, interrogated a number of hard-coal dealers Oct. 17. As the inquiry was not yet fully under way, the officials declined to discuss the information they had obtained.

Kanawha Operators in Big Annual Meeting

The meeting of the Kanawha Coal Operators' Association at Charleston last week was better attended than any previous gathering of that association. New membership representing more than three million tons was enrolled. The election of officers resulted as follows: John Laing, president; H. D. Morton, vice-president; John L. Dickinson, treasurer. D. C. Kennedy was re-elected secretary. Directors were named as follows: E. O. Dana, F. O. Harris, W. M. Wiley, H. L. Warner, W. C. Mitchell, C. A. Cabell, F. H. Morton, H. D. Morton, John Laing.

One of the features of the meeting was a luncheon at the Kanawha Hotel. Colonel Quinn Morton acted as toastmaster. When President Laing was introduced he was given an ovation. In his remarks he stressed the necessity of co-operation among operators to meet the crisis through which the coal industry is passing. Harry L. Gandy, secretary of the National Coal Association, reviewed the conditions which led to the creation of the Coal Commission

and discussed the plans of the Bituminous Operators' Special Committee. Colonel Chris Hetzel spoke in a humorous vein and urged co-operation. Other speakers were H. D. Morton and E. O. Dana.

N. C. A. to Have Full-Time President?

Whether or not the presidency of the National Coal Association will be given a salary status will be determined in the near future by the Bituminous Operators' Special Committee. It has been recognized since the organization of the association that a great sacrifice was required of the man elected to the presidency. The duties of that office are such as to require a considerable portion of the time of the incumbent. This has been the case particularly during the trying times of the last two administrations.

The committee is to determine whether or not a salary should be paid for part-time work—sufficient to equalize the loss of time from the president's private business—or to place the salary at a figure sufficiently attractive to justify the president in giving his entire time to the affairs of the association. Some of the members of the organization are anxious to see the president of the National Coal Association made a sort of high priest of the bituminous industry, a position comparable to that occupied by Will Hays in the motion-picture industry.

It is not the idea to give the president a permanent status, it is understood. Even if it should be decided to attach a salary to the presidency it is probable that re-election would be necessary each year in conformity with the constitution of the association. If some such proposal were to be made effective, it is practically certain that the membership of the association will insist on the acceptance of the place by J. C. Brydon.

O'Malley Orders Gouging Inquiry

Edwin J. O'Malley, Commissioner of Public Markets of New York City, made the charge Oct. 20 that the "old-line coal companies," which at present claim to be offering coal to consumers at the lowest prices, are resorting to unfair methods and sending most of their production to independents at increased rates, and asked his Deputy Commissioner, Mrs. Louis Reed Welzmler, to investigate.

Mr. O'Malley said he had been told that while the companies which control 80 per cent of the anthracite advertise coal at low prices, and actually send out a certain quantity at these prices, the balance of their production is sold to the independents at an increased rate. This, he said, was characterized as "backdoor coal."

"In order to control the entire coal situation," said O'Malley, "the old-line companies sell only a limited quantity to a favored few retailers. The retailers out of the ring are not permitted to buy of the old-line companies and are therefore forced to purchase coal of the high-priced independents, to whom the old-line companies have sold by way of the 'back door.' These unfortunate retailers are obliged to charge the consumer what are apparently exorbitant prices."

Dr. E. W. Parker, director of the Anthracite Bureau of Information at Philadelphia, reported Oct. 20 that between April 1 and Aug. 31 this year 2,914,873 tons of domestic anthracite were shipped into New York and its environs, against 2,455,416 tons in the same period in 1921.

The coal survey of New York ordered by Police Commissioner Enright was completed Oct. 20 and showed a total of 183,230 tons of all kinds of coal and substitutes on hand by dealers. The report showed that there is no great surplus of coal in the city, and most of the 129 dealers interviewed said there is no certainty as to the amount they can obtain from one week to another. The supply at present is just about enough to meet the demand for domestic coal.

Commissioner Enright's survey revealed that prices range from \$14.25 to \$15.25 per ton. All dealers agree that there is no fear of a coal famine.

GERMANY HAS MORE DESTITUTE MILLIONAIRES than were ever known in history.—*Birmingham Age-Herald*.

Trade Commission Issues First Report on Anthracite Wholesalers' Margins

Margins realized on individual cars by wholesalers of anthracite who purchase and sell in carload lots "without physically handling the coal" ranged during the week ended Sept. 22 from 10c. to \$1.50 per ton, while on steam sizes it ranged from a loss of 15c. per ton to gains of 70c. per ton, according to the Federal Trade Commission, which has just issued the first of a series of weekly reports. The margins realized on over 50 per cent of the sales reported of anthracite steam coal, the Commission says, were 10c. or 25c. per ton, while nearly 78 per cent was at 10c., 15c., 20c., and 25c. per ton.

President Coolidge requested the Federal Trade Commission to examine the findings of fact of the U. S. Coal Commission to ascertain whether the passing of anthracite, especially, through numerous hands before it reaches the consumer is really a device by which the price is unduly raised and, perhaps, constitutes an unfair trade practice. The Trade Commission is continuing the reporting plan formerly used by the Coal Commission in order to obtain first-hand information currently regarding the margins taken and the number of wholesalers intervening between the mine and the retailer.

"Sixty per cent of the total number of cars of domestic sizes of coal reported for the week ended Sept. 22," the Trade Commission says, "were purchased by the reporting wholesaler from a producer and sold to a retailer or consumer, thus passing through the hands of but one wholesaler. Thirty-two per cent were purchased by the reporting wholesaler from a wholesaler and sold to a retailer, thus interposing at least two and possibly more wholesalers between the mine and the consumer. Six per cent were bought by the reporting wholesaler from a producer and sold to a wholesaler, thus interposing at least two wholesalers, and 2 per cent were bought by the reporting wholesaler from a wholesaler and sold to a wholesaler, thus interposing at least three wholesalers between the mine and the consumer. Thus 40 per cent of the carloads of domestic sizes reported were handled by two or more wholesalers."

Chemical Engineers Preparing Program

The tentative program for the sixteenth annual meeting of the American Institute of Chemical Engineers, which will be held in Washington, Dec. 5, 6 and 7, has been drawn up. As the auditoriums at the various bureaus are not large enough to accommodate all those who will be in attendance at the meeting, it has been decided that all sessions will be at the Willard Hotel. This will in no way interfere with the plan to make tours of the bureaus in which chemists are particularly interested. The tentative program includes a paper on "Combustion of Coke, a Typical Bureau of Mines Problem of Importance to the Chemical Engineer," by A. C. Fieldner; one on "Testing of Explosives for Governmental and Commercial Use," by J. W. Paul, and one on "Fuel Research of the Bureau of Mines," by O. P. Hood, as well as addresses by Dr. George Otis Smith, director of the Geological Survey; H. Foster Bain, chief of the Bureau of Mines, and others.

German Export of Coal Crippled by Loss of Upper Silesia

Exports of coal and coke from Germany, according to reports of the German Bureau of Statistics, during the first half of this year, in comparison with the corresponding months of 1922 and 1913, are shown in the following table, in metric tons:

	1923	1922	1913
Bituminous coal.....	556,080	4,243,620	16,368,690
Brown coal.....	785	9,170	3,502,911
Coke.....	134,595	558,324	3,405,202

The decline in exports of bituminous coal is accounted for by the partition of Upper Silesia from Germany to Poland. Holland as the only remaining large buyer of

German coal received from January to June, 1923, 448,000 tons out of the total of 556,000 tons of bituminous coal exported. Smaller quantities were shipped to Switzerland, Austria and Czechoslovakia.

Leading Engineers Attend Mine, Mechanical And Electrical Engineers' Meeting

Members of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers met for their third annual convention at Huntington, W. Va., Oct. 19 and 20.

The meeting this year was the largest held by the association, many new members having been added within the last year. Papers were presented on several of the vital questions on mine application of electrical and mechanical engineering. The papers were discussed by prominent mine electrical engineers of the country, many of whom have been attracted to the society by the important work it has accomplished within the short time it has been in existence.

Two of the papers presented at the convention appeared in the Oct. 18 issue of *Coal Age*, and another appears in this issue.

Considerable discussion took place on the following papers: "Hoisting Equipment," by M. A. Maxwell; "Equipment Records," by J. H. Edwards, and "Manufacturer's Service in Supplying Repair Parts," by F. M. Reigher. Deep interest was taken in an informal discussion on the subject of Motor-Generator Sets vs. Rotary Converters for Mine Service. This question was ably discussed from many angles by leading representatives of the mining manufacturing, consulting and power companies' engineers.

The convention was concluded with the election of new officers and a dinner. R. R. Webster, of the Elkhorn Piney Coal Mining Co., of Weeksbury, Ky., was elected president; F. M. Reigher, electrical engineer, American Coal Co., of Bluefield, W. Va., vice-president, and Herbert Smith, of Huntington, W. Va., was re-elected secretary-treasurer.

Cement Output and Shipments Drop

Production of portland cement during September, 1923, according to the Geological Survey, totaled 13,109,000 barrels, as compared with 11,424,000 barrels in the corresponding month of 1922, and 12,967,000 barrels in August, 1923. Shipments for the month were 13,698,000 barrels as compared with 12,444,000 barrels in September, 1922, and 13,971,000 barrels in August, 1923. Stocks at the end of September amounted to 5,492,000 barrels, as compared with 4,724,000 in September, 1922, and 6,080,000 barrels in August of this year.

REMARKABLE EXAMPLES of human endurance and perseverance are recorded in connection with the flooding of the Redding coal mine near Glasgow, Scotland. Five men were rescued alive after 214 hours imprisonment. None of the men was the worse for his nine-day fast. The incident parallels the rescue of five Welsh miners after nine days imprisonment in 1877 in a Rhondda Valley coal mine. While the men in the Scottish mine had no food, they were trapped in a part of the mine where potable water was available, and where fresh air could be had. Great credit is being given the rescuers for the tireless, night-and-day effort they made to reach the entombed men.

FRED R. LOW, editor of *Power*, has been elected president of the American Society of Mechanical Engineers for the coming year. He will succeed John L. Harrington, of Kansas City, Mo. The election was conducted from the national headquarters of the society, in New York City, by mail ballot, more than 18,000 members participating.

REHEARING OF THE ASSIGNED-CAR CASE began in Washington Oct. 22 before Commissioner Aitchison and William Bartel, director of service of the Interstate Commerce Commission. The first day was devoted to testimony by the railroads, which argued for retention of the assigned-car rule as necessary to obtain adequate supplies of fuel for their requirements.

Soft-Coal Industry to Demonstrate That It Can Improve Its Own Practices

Bituminous Operators' Special Committee Will Make Close Study of Findings of Coal Commission and Voluntarily Put Into Effect Practical Suggestions—To Publish Figures on Costs, Earnings and Wages

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

The Bituminous Operators' Special Committee, which now has become a permanent institution, is going to take full advantage of the interim prior to the convening of Congress to demonstrate that the industry is capable of improving its own practices. It is in no way an admission on the part of the operators of any outstanding and flagrant delinquencies on their part. If they can be rid of strikes and governmental interference, they point out, the country will be supplied with all the coal that it can use at reasonable prices. Nevertheless it is recognized that a public demand exists for basic figures and these are going to be furnished on a voluntary basis. Mr. Brydon was in Washington last week, conferring with government officials.

A detailed study is being made of the reports of the Harding Coal Commission, with the idea of carrying into effect voluntarily any practical suggestion made by the Commission. This is subject, of course, to the committee's ability to finance the work involved. Incidentally it may be mentioned that the matter of financing such activities is becoming increasingly difficult in the period when a considerable portion of the tonnage is being sold with little or no margin of profit.

In view of the fact that the committee has enjoyed only a week of life under its new status, plans have not advanced very far. At this time all activities are being concentrated on plans for publishing figures on costs, earnings and wages. If this movement has the support of operators generally it may head off legislation providing compulsory returns to the Interstate Commerce Commission.

If the plan is successful it must furnish the information in which the public is most interested. It happens that the fields in which the public has the greatest interest are those less likely to make voluntary returns.

WAGE RETURNS A SUBJECT OF WIDESPREAD INTEREST

Returns on wages would seem to be among the more important things which the operators could do in their own interest. This is particularly true of wages paid in the non-union fields. If it could be brought home to the public that earnings of \$500 per month on the part of an individual coal miner is not the exceptional performance of an exceptional man and that literally scores of men earn that much, the public might make its influence felt when the men come forward with requests for an increase of 15 or 20 per cent, as they probably will do next spring. While the public is fairly familiar with the wage rates in the union field, there is much opportunity to point out to them just how this wage scale works out. There is comparatively little knowledge of wage rates in the non-union fields and since they change frequently there is greater need for basic information concerning them.

Perhaps this is a good time for the Bituminous Operators' Special Committee or the National Coal Association as such to enter upon the consideration of technical matters. Practically every other large national association undertakes work of that character. The need is greater in coal mining than in nearly any other industry. None disputes that coal-mining properties are poorly managed from an engineering standpoint. There are great wastes which could be eliminated and it even might be to the interest of the industry were the national association to undertake to instruct consumers how to get the most out of their coal rather than have them convert their power plants to use oil.

Since the public is demanding more than the figures which operators can furnish it might be advisable for the National, as the most powerful association within the industry, to take the initiative in formulating a program in which the wholesalers and retailers would participate.

In the whole gamut of questions arising in industrial relations, other than wages and hours, a fertile field is offered to the National Coal Association. The opportunity for doing something constructive in the matter of housing alone is great.

Statistics covering production, distribution and stocks are inadequate. There is no thought that this activity should not remain where it is, in the Geological Survey. The service should be expanded, particularly in regard to distribution of stocks. The only way that can be done is to bring the need forcibly before Congress so that the necessary funds may be appropriated.

STILL MUCH ROOM FOR IMPROVEMENT

This does not pretend to be a full list of the many things which the industry can do to improve itself. There are literally thousands of things, statistical and otherwise, which would contribute in no small way to the industry's improvement. A golden opportunity exists to demonstrate, prior to the convening of Congress, what can be done in the public interest and in the interest of all branches of the coal trade.

The question may be asked as to the probability of the acceptance by the public of data put out by an interested source. All that is necessary to answer such a question is to point to the American Iron and Steel Institute, the American Railway Association, the National Lumber Manufacturers' Association or any one of many other organizations. Their figures are accepted by the public at their face value. No one thinks of questioning the figures covering the production of steel ingots. Financial operations of great magnitude are influenced by the Iron and Steel Institute's figures on unfilled orders. The National Lumber Manufacturers' Association gathers by telegraph each week and distributes at great expense figures as to lumber productions, shipments and orders. Business accepts them and so does the public. They would be willing to repose the same confidence in the National Coal Association. The coal operators filed good briefs with the Coal Commission. They now have an opportunity, and it may head off adverse legislation if they demonstrate their ability to do voluntarily some of the things which otherwise might be made a legal obligation.

Government Fuel Yard Seeks Coal Bids

The Government Fuel Yard, Washington, D. C., seeks the submission of bids on 14,700 gross tons of low-volatile bituminous run-of-mine coal to cover its fuel requirements for the period from Nov. 15 to March 31, next. The tonnage called for is for use in plants located on the Baltimore & Ohio R.R. only. "A consideration of freight rates limits, therefore," it is announced, "bids on this tonnage to coal from mines on the B. & O. or connecting lines." Sealed proposals to supply the tonnage will be received by George S. Pope, Chief Engineer, Government Fuel Yard, Room 1139, Interior Department, up to 2 p.m. Oct. 31 and then publicly opened.

Production and the Market

Weekly Review

The soft-coal market continues to show practically the same conditions that have prevailed for several weeks. Demand continues slow. Production took a slight upturn but a decline is indicated for last week. Steam coals are moving slowly, while domestic coals show a slightly better demand in some parts. The railroads are reported by the American Railway Association to hold 17,663,448 tons of bituminous coal, of which 15,605,415 tons is in stockpiles and 2,058,033 tons is in cars. This total compares with 16,365,693 tons in reserve on Sept. 1 and 6,756,886 tons on Jan. 1. Spot prices in some districts show a slight advance but these are almost offset by declines in others.

Coal Age Index for the first time in seven weeks shows an advance, registering 186 on Oct. 22, an increase of one point from the previous week, with an average price of \$2.25. Increases in southern Illinois, Springfield, Standard and Kanawha coals were practically offset by declines in eastern and western Kentucky, Clearfield, Cambria, Somerset and Pocahontas fields.

Production of soft coal during the week ended Oct. 13 is estimated by the Geological Survey at 10,771,000 net tons, an increase of 71,000 tons over the previous week, but an appreciable decrease is indicated for last week.

CONSUMERS RELUCTANT TO BUY

Market dullness is reported in nearly all sections. Consumers are reluctant to buy, as they are well stocked. A slight improvement in spot buying is reported from the Middle West, particularly for domestic coals, due to slightly lower temperatures, while domestic business in St. Louis is tied up because of mild weather, and there is no demand for anthracite, coke or smokeless coal. The Kentucky markets are in bad shape, while the situation in the Northwest is not at all satisfactory.

The Ohio markets are quiet, with no change reported

from the Pittsburgh field. Dullness in the textile industry, with heavy reserve stocks of coal on hand continue to dominate the New England situation. Prices are at low levels.

Production of anthracite for the week ended Oct. 13 amounted to 2,009,000 net tons, according to the report of the Geological Survey. In the previous week it was 2,015,000 tons, which was a drop of 10,000 tons from

	Week Ended Oct. 15	Season to Oct. 15
Cargo	817,044	23,616,366
Fuel	40,559	1,286,398
Totals	857,603	24,902,764

the week of Sept. 29. Final returns of anthracite shipments in September place the total output for that month at 2,917,000 tons, which was 5,951,000 tons less than production in August, the loss being attributed to the miner's strike. Despite this loss of production during the strike, however, the cumulative output during the first nine months of 1923 compares favorably with that in years of large production. Domestic coals continue in heavy demand, while steam coals move slowly.

All-rail shipments of bituminous coal into New England during the period April 7-Sept. 29 amounted to

(a) Subject to revision. (b) Revised from last report.

111,497 cars, according to a survey of the coal industry issued by F. R. Wadleigh, Chief, Coal Division, Department of Commerce. During the corresponding periods of 1922 and 1921 the shipments were 28,601 and 73,100 cars, respectively. All-rail shipments of anthracite into the same territory during the same period were 83,273 cars in 1923, 17,801 cars in 1922 and 82,081 cars in 1921. During the five months April-August bituminous coal dumped into vessels at North Atlantic ports destined for New England amounted to 5,192,036 tons.

Export demand is slow and the outlook is not encouraging; the German situation is being watched closely.

Midwest Market Improves

A slight strengthening of the market in spots was felt throughout the Middle West during the last two days of last week. Cool weather made an almost imperceptible impression on domestic demand. Even slight changes are

noticeable in a season when the market is as flat as it is now. Southern Illinois lump holds up fairly well to the association circular of \$4.35 with little selling under \$4, but the volume shipped is low. A number of mines are down. It is said in St. Louis that there has never been a time since southern Illinois coal became a factor in that city's market when so little Franklin County coal has been offered there. The southern field has a good many "no bills" in middle-sized coal.

Central Illinois commercial mines also are running slowly so as to avoid "no bills" as much as possible. The best lump produced there holds up above \$3 with a top price of \$3.25. Standard district lump has toned up in price a little. An average increase of about 15c. a ton raises it to \$3@3.25. Screenings are not on hand in such huge quantities nowadays. The result is Southern Illinois operators place theirs at \$1.40@1.50 and central edges up about 10c. to 85c.@1. However, Standard operators suffer a slight lowering on screenings to compensate for their fairly good lump market. The price is 45c.@50c. Western Kentucky screenings are as low, but they do not find eager acceptance. Evidently steam buyers

* Net tons, f.o.b. mines. † Advances over previous week shown in heavy type, declines in italics.

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

feel they can afford to wait for another slump in higher grade screenings.

St. Louis Remains Dull

Mild weather continues to tie up domestic business in St. Louis and while a little is moving it is in small quantities and of the cheaper grades. Dealers have their yards full and reports show that there is no demand for anthracite, smokeless or coke. Country domestic calls show that the demand is mostly for middle-priced coals and almost universally the lump size in spite of efforts on the part of shippers to move egg and nut.

Wagonload steam has picked up during the last few days on account of wet weather, but carload is still lagging, with no country call at all and practically nothing moving to the Northwestern or Chicago markets. Railroad tonnage also has dropped off.

The Kentucky coal market is in poor shape. While a considerable amount of tonnage is being moved, it is not on a profitable basis for the operator or the jobber. Some operators selling direct are quoting prices which the jobber can meet only by cutting his commission down to practically nothing. There is too much coal being offered for the market to absorb. Retailers in some instances have fair yard stocks, but others are buying merely as they need coal, and playing for a lower market later in the fall.

Some ridiculously low prices have been reported in the local market during the week. A jobber reported inability to sell a car of Elkhorn mine-run, representing distress fuel, at 85c. Some good mine-run has been quoted as low as \$1.25 from eastern Kentucky. Harlan County is asking \$2@ \$2.25 for gas mine-run, but jobbers report that it is being offered at \$1.50 and up by some mines, and the situation in the Hazard field is much the same.

Northwestern Trade Still Sluggish

The warmth of the past week was sufficient to keep the Northwestern coal trade in the dumps. A decline in domestic demand in Duluth did not cause much worry, however, for dealers were confident that the colder weather promised for this week would snap things up. They are laying in all the anthracite they can handle. However, movement of both hard and soft coal to the upper lake docks was small during the week. Only thirty-one cargoes reached the Head-of-the-Lakes, of which but two were of anthracite. At Duluth prices held firm, in spite of slack trade, on everything but Kentucky, splint and Pocahontas screenings. These coals are off because of excess supply and because dock owners want to unload them before a freeze-up.

"No demand; little doing," is the laconic market opinion in Milwaukee. The recent 70c.@80c. advance in hard coal has damped out all keenness in demand for anthracite and even the low prices at which Pocahontas, as a hard-coal substitute, is offered has not stimulated buying much. Docks appear to be trying to get all the hard coal they can, however.

Milwaukee receipts during the first half of October aggregated 79,986 tons, making the season's receipts of hard coal since the opening of navigation 713,625 tons. October receipts of soft coal thus far total 233,772 tons, making the season's receipts 2,319,121 tons. These figures bring the total receipts of both hard and soft coal since navigation opened up to 3,032,746 tons.

Trade at Minneapolis has been low. The market on soft coals has steadied somewhat as the vast excess of coal available a couple of weeks ago thinned out a little, but nobody is buying in quantity and competition continues sharp. Hard coal has moved readily enough into the country but the cities still are partly unsupplied and will have to buy at the new increased price since pre-strike coal is exhausted.

West Does Little

There is little to relieve the drabness of the market condition in the West and Southwest. Around Kansas City steam demand continues light and screenings continue to back up on the mines. Demand for domestic sizes of both Arkansas smokeless and Kansas coals is fair. In Colorado demand is so small that nothing moves readily and mine running time has fallen off still further. The September output was 863,500 tons, which was 26,400 tons under September of 1922.

In Utah the little flurry of trade brought on by the recent changes in price lists has about blown over and business is slowing up. A car shortage is making itself felt. While the Pacific coast and Northwestern markets remain dull, Utah and Idaho are taking a good deal of domestic coal. Steam demand seems to be off.

Ohio Market Sluggish

Rejections, coal on commission, coal in distress and a demand that is even more sluggish than draggy are the high lights in the Cincinnati market. There is a certain amount of firmness in the domestic coal market. Southeastern Kentucky mines and the smaller operations on the Big Sandy are beginning to feel the pinch of high costs and low returns and there are a number of the mines there that have closed down or are contemplating doing so as a means of stopping their losses. There has been no great change in the low-volatile situation except that some brokers are offering smokeless lump and egg now at \$6. Retail prices are unchanged.

Warm weather together with heavy stocks on the part of steam-coal users has tended to reduce demand in the Columbus market. Little hope is held out for the present.

Retail dealers are buying for immediate needs generally and some of them have some demand for Pocahontas and other smokeless grades, but the majority are delivering only a small tonnage. Ohio-mined coals are not selling as well as formerly for domestic purposes although some tonnage is moving both from the Hocking Valley and Pomeroy Bend fields. Purchasing agents are showing no interest in the steam-coal situation. Reserves are sufficient for from sixty to ninety days and at present utilities are the best customers, with the railroads taking a fair-sized tonnage. Screenings are the weakest, with prices low.

The Cleveland market is in the doldrums, operators and jobbers asserting that it is duller now than for many years. Distress coal continues to move into industrial centers, with the result that in many instances sales of this coal are made from 10c. to 15c. per ton below what might be considered the spot range. Public utilities are not storing as much coal this fall as they have in the past.

The Pittsburgh coal market does not seem to have lost any more ground last week, but it has not improved either. Consumption is large, but consumers are not in the market to any extent, being supplied either by regular contracts or by arrangements whereby prices are adjusted or agreed upon weekly or monthly. The open market demand for coal is very light and there are no indications at present that it will improve. The market for Pittsburgh district coals is disturbed also by the greater competition of non-union fields, the low prices quoted for some of this product having an influence on the market.

In order to keep their mines in operation it is reported that coal operators in the central Pennsylvania district are loading cars and holding them on the sidings. The daily loadings in September averaged 3,101 cars as compared with 3,200 cars in August, while the daily loadings during the first fourteen days of October averaged 2,342 cars.

No Improvement in New England

In New England the steam trade is still very much in the doldrums. Prices are at low levels whether all rail or by water and there are no signs of improvement. The textile industry is still under heavy restriction and those mills that still use coal have large stocks that will meet probable requirements for months to come.

At Hampton Roads there continue large accumulations and quotations have eased off to \$4.50 per gross ton f.o.b. vessel for No. 1 navy standard grades. On cars at Boston and Providence sales have been made at as low as \$5.75 per gross ton and there are still cargoes afloat that factors are trying to force on the market.

Receipts all-rail have diminished materially. Even the railroads are taking less tonnage than was the case during August and September. All the agencies are combing over consuming territory, but their efforts meet with only light response. What scattering purchases are made are of coals from low-cost mines where operators have scaled quotations down to a minimum.

Little Change in Atlantic Seaboard Markets

There is no appreciable change in the soft-coal markets along the Atlantic seaboard. At New York demand is light and prices easy. Spot coal moves slowly. In the

Philadelphia market nothing has developed to encourage the producer and the situation last week was quieter than during the previous week. Changed weather conditions, it is believed, will be necessary before there is a change in the situation. The Baltimore market is usually flat and prices are low. Although there is not much demand for either high- or low-volatile coals, says a report from West Virginia, there has been no appreciable reduction in the output. "No market" losses in the Virginia territory are not so heavy.

The market at Birmingham is weak and featured by the smallest volume of new business so far recorded this year. No interest is being shown by buyers beyond obtaining immediate requirements, and these are either very small or are taken care of by reserve stocks. The domestic market, which has held up satisfactorily until recently, is now sluggish. The small amount of new business offered is placed in many instances with the smaller producers at somewhat shaded figures. Furnace mines are operating three to five days a week and commercial mines with few exceptions not over three days.

Movement of soft coal through the lower Lake ports amounted to 857,603 net tons during the week ended Oct. 14, an increase of 19,093 tons when compared with the previous week. Lake shipments of anthracite during the second week in October totaled 125,610 net tons, and were confined to Buffalo, there being no shipments through Erie. Cumulative shipments of anthracite in 1923 amount to 2,633,909 tons.

Domestic Anthracite Market Brisk

The anthracite market for domestic coals continues brisk, but the steam sizes are moving slowly. Most retail dealers are anxious for heavier shipments of the larger coals, particularly stove. In the territory served by the New York market strong efforts are necessary to move steam coals and some producers and shippers are offering inducements to buyers. Most of the larger companies find it necessary to store these coals because of the small demand. There is no appreciable change in the Philadelphia market, most dealers continuing to be short of the most-wanted coals. Consumers persist in their preference for stove and chestnut sizes, the latter size being in stronger demand than the former. The steam coals are draggy, with the companies making strong efforts to dispose of these coals. The arrival of 631 cars of anthracite at Baltimore during the first two weeks in October resulted in easier conditions there and enabled the retail dealers to catch up with their orders.

Production of beehive coke continues downward, says the Geological Survey, reports for the week ended Oct. 13 showing an estimated output of 284,000 net tons as compared with 312,000 tons during the previous week.

Foreign Market And Export News

Buyers in Welsh Market Adopt Bear Tactics; Improvement Noted at Newcastle

Production of coal in Great Britain's mines during the week ended Oct. 6 amounted to 5,528,000 tons, says a cable to *Coal Age*. This is a decline of 47,000 tons from the previous week, but an increase of 319,000 tons when compared with the output of the corresponding week of last year.

The condition of the Welsh coal market is little if any better than a week ago. Business is mainly of a hand-to-mouth character and demands are being met from the accumulated stocks. Buyers, in hope of improvements in reparation deliveries, are adopting bear tactics and operators are forced to sell at cut prices. Purchases are being kept to the minimum and the outlook for the future is causing nervousness among consumers. Operators refuse to sell for future delivery on the basis of current prices.

The Newcastle market has improved. Prices have changed very little, but the undertone is stronger and operators are more confident. Inquiries have expanded, are more varied and practically all classes of coal are selling well. Business with Germany, France and the Baltic has increased. It is anticipated that in the event of a settlement of the Ruhr problem, French purchases will diminish but that Germany must buy British coal for some months to come.

There is something of the nature of a slump in the Swansea anthracite market.

Tax Lifting Results in Lower Prices

The United States Department of Commerce at Washington has received a cablegram from Commercial Attaché Herring at Berlin stating that the abandonment of 30 per cent coal tax and further price reductions by from 10 to 15 per cent became effective Oct. 15, resulting in the following reduced prices in gold marks per metric ton: Ruhr pitcoal 24.92; Westphalian nut 33.78; Selesian lumps 19; Rhenish lignite briquets 15.15. This was due to violent protests on the part of the industry and the general public against the former prohibitive prices.

French Coal Output Increasing

With coal production in France increasing, receipts of German, Belgian and British coals are decreasing. Demand for house coals is comparatively quiet at present, but expectations are that this market will soon revive. The Belgian export decree is said to be interfering considerably with receipts of Belgian coals by France and also the execution of private contracts which have been closed. On the other hand business terms with Great Britain are easier and small price concessions are being made for prompt delivery. A shortage of rolling stock is reported in both France and Belgium.

Coke receipts by the S.C.O.F. during September amounted to 135,000 tons, an increase of 30,000 tons over August shipments, while perequation price for October has been fixed at 212 fr., as

compared with 200 fr. in September. Every possible effort is being made by metallurgists to increase the production of coke. Cokeries destroyed during the war are being rebuilt and new cokeries are being constructed in various parts.

During August production of coal and lignite amounted to 3,405,028 metric tons, as compared with 3,214,814 tons in July, while during the same month coke production was 180,860 tons as compared with 178,427 tons in July.

Ruhr Coal Shipped to Italy

Shipments of reparation coal from the Ruhr to Italy during the past five years follow: 1919, 114,000 tons; 1920, 1,330,400 tons; 1921, 2,765,200 tons; 1922, 2,480,000 tons, and 1923, 850,000 tons.

Movement at Hampton Roads

Below Normal

Business at Hampton Roads was dull last week, with the bunker trade showing the only activity. Coastwise shipments were not holding up to the record, while export business moved on a very slender schedule.

Movement at the piers was below normal, and the market was weak. Prices were at a low level, but buyers were not tempted to any great degree. Coal dumpings were considerably below the activity at the same period last year.

Shippers were not optimistic over the foreign trade situation, and did not look forward to any great movement of coal abroad.

News Items From Field and Trade

ALABAMA

Walter Moore, of the Pratt Fuel Co., Birmingham, has closed a deal whereby his company obtains possession of the Red Oak Mine, of the Disney Coal Co., near Cordova, Walker County. The operation formerly belonged to A. R. Disney and is a slope on the Mt. Carmel seam and is served by the Frisco railroad. The mine is electrified, the coal being cut by machine and motor haulage being employed.

The Hercules Coal Mining Co. has been incorporated with a capital stock of \$2,000, with headquarters at Henry Ellen. W. L. Simmons is president; J. J. Lee vice-president, and F. G. Moore, secretary of the company.

The Hercules Powder Co. has acquired about 600 acres of land near Bessemer, Jefferson County, on which it is understood a large, modern plant will be erected. The company is now operating the old plant of the Aetna Explosive Co., which it acquired through sale by a federal receivership several years ago, but on account of growth in its business a larger and more modern plant is made essential.

ARKANSAS

F. O. Sandstrom, secretary and traffic manager of the Colorado and New Mexico Coal Operators Association was in Chicago the week of Oct. 15 with A. Vogl, attorney for the Colorado operators, compiling and filing the brief for the recent Western rate hearing held in Denver.

ILLINOIS

A report current in railroad and coal circles that the Illinois Central R.R. is going to build a line into the Harrisburg field of southern Illinois has been unofficially denied by the railroad, though the denial is not positive and final. If such a line were built it would give the Illinois Central access into a region practically controlled in the past by the Big Four.

The mine of the Star Coal & Mining Co. at Freeburg, in St. Clair County, was sold Monday, Oct. 15, by order of the court at public sale in Belleville to C. A. Gent for \$6,000. The property had been in the hands of D. S. Gent, as receiver.

The game of "freeze out" between the union miners and the owners of No. 3 mine of the Brewerton Coal Co. at Lincoln goes merrily on. The miners struck Sept. 26 because the checkweighman insisted that a housing that had been built around the scale beam obstructed his view. The mine was shut down and has been in process of dismantling. The strike was pulled without official union authorization although Freeman Thompson, subdistrict president, has voiced his sanction of it since in a number of outbursts of publicity directed at the company and its president, W. A. Brewerton. Since the company started pulling rails and equipment out of the mine, giving every indication of abandoning a property that has given almost continuous employment to 200 men all summer, much pressure by the town of Lincoln and others interested has been brought upon both company and miners to settle. The company is able to fill its contracts from its neighboring mines and no settlement has yet been made.

The Odin Coal Co., of Odin, is rebuilding its tippie, recently destroyed by fire, equipping it with modern type screens and shaker booms. Roberts & Schaefer, of Chicago, have the contract.

The Gartside Coal Co.'s mine No. 4 at Murphysboro, in the Big Muddy seam, has been dismantled and practically everything sold, excepting the tippie and hoisting engines and one boiler. Depressed market conditions are responsible. This company is the oldest operating company in the southern Illinois field and possibly in the state of Illinois. Organized in 1843, it has had continued operating existence for 80 years. In the early days they operated a mine in and around St. Louis just west of the Missouri Botanical Garden. For over 30 years the Gartside Coal Co. brought its coal across the Mississippi in wagons on boats before any railroads crossed the river. The company has been an active retailer in St. Louis since 1843.

Stewart S. Shive, president of the Mammoth Coal Co., of Benton, wrote *Coal Age* Oct. 15 that his company has leased from the United Mine Workers of Illinois the strip mine formerly owned by the Southern Illinois Coal Co. and is now operating it. This is the Herrin property around which the 1922 riot centered.

The L. A. Papke Construction Co. is erecting a warehouse at the new town of Nason, in preparation for erecting 100 or more houses, which will be for sale to miners locating in the new town. A new house will be completed every four days. With the completion of the railroad into Nason, building operations at the new mining town are proceeding rapidly.

T. L. Lewis, Charleston, W. Va., representing the National Coal Association, Washington, D. C., was a speaker before the Rotary Club of Quincy, Oct. 16, on the subject "Causes for the High Cost of Coal." Mr. Lewis has been an active worker in the soft coal fields for thirty years.

The J. H. Patterson Co., operating coal and lumber yards in nine towns, will remove its main offices from Marengo to Rockford Nov. 1. Office rooms have been taken in the Phoenix Building, North Main and Mulberry Streets. The company operates yards in Freeport, Rochelle, Marengo, Huntley, Union, Wauconda, Roscoe, Harlem and Rockford.

The Eureka Coal & Dock Co., of Chicago, has increased its capital from \$100,000 to \$300,000.

The Burke Coal Corporation, of Pinckneyville has been incorporated by J. T. Burke, W. A. Lafont and E. C. Dodge with a capital of \$100,000 to mine and sell coal.

Several coal operators in St. Louis, Mo., with mines in the Fifth and Ninth Districts of Illinois have received letters from D. R. Francis & Bro. of St. Louis, asking if their mines are for sale. This would indicate that another effort will be made such as was made about 3 years ago to gather in several of these mines now while the coal market is in a demoralized condition. It would have a stabilizing effect if it could be put through.

Nat McFadden, engineer at Taylorville for the Peabody Coal Co., will act as instructor in the class for preparation for mine managers in the night school for tradesmen conducted by the Taylorville high school. This class will prepare the men who expect to take the state examination as mine managers.

The five men injured when a cage fell 100 ft. in the Decatur Coal Co.'s mine at Decatur will recover. All were painfully and severely bruised, broken bones being especially numerous. The accident was caused by the snapping of a hoisting cable.

Notices have been posted announcing the closing of the Taylor Springs mine of the Indiana & Illinois Coal Corporation near Hillsboro. The mine will be sealed.

INDIANA

Hearing of the case of the J. Woolley Coal Co., of Evansville, against the Southern Railroad Co. asking for damages of \$105,000, has begun before federal examiners for the Interstate Commerce Commission last week. The coal company alleges the railroad discriminated in distributing coal cars last winter. It also is alleged that railroad supplied cars to the company's competitors and that the loss in business because of this alleged discrimination amounted to more than \$105,000. The railroad company denied the allegation, and maintained that in these months there was a shortage in coal cars, due to the shopmen's strike. Evidence submitted will be taken to the interstate commerce commission at Washington for a decision.

Failure of water supply from a 50-acre lake of the Enos Coal Co., in Pike County, resulted in the company endeavoring to dam a branch of the Patoka River, which would include damming a \$40,000 drainage ditch built by farmers of the adjoining property. The Pike County Commissioners refused permission for the dam when the property owners filed complaint. The company went on cutting timber and getting ready with a big force of men to construct

the dam, when an injunction was filed at Jasper, by Leonard Farmer. It was granted, and the company has been notified of the action, pending a hearing of the case.

Between four and five thousand miners in Indiana are out of work this fall, according to an estimate made Wednesday, Oct. 17 by Carl J. Fletcher, Indianapolis, vice-president of the Knox Coal Mining Co. An overdevelopment of the entire coal industry, combined with large shipments from Eastern non-union fields into Indiana was blamed by Fletcher for the present situation. Most of the miners are finding temporary occupation in other industries, he said.

KENTUCKY

It is reported that the Consolidation Coal Co., in the McRoberts-Jenkins neighborhood, has been working full time in its string of mines and employing night shifts, getting out a heavy tonnage. A good many of the big companies, which have large tonnage in hand, are operating as full as car supply will permit. Business is also heavy in the Harlan and Hazard fields as well as Elkhorn fields, but prices are not satisfactory since steam consumers slowed up on buying screenings.

Charles I. Dawson, Republican nominee for Governor, who is making a stump tour of the state, is plainly denouncing plans for any coal sales or tonnage tax, and pledging his full effort to prevent imposition of any such tax by the next session of the Legislature. Dawson is also panning W. J. Fields, Democratic nominee, for failure to state his position in the coal tax controversy, which promises to be the big issue of the next legislative session.

Three men are dead at Hazard, as a result of a fight in the clubhouse of the Superior Coal Co., No. 4, at Combs just out from Hazard, on Oct. 12, in which Anse Begley, telegraph operator for the Louisville & Nashville R.R., John Baker and his brother, Bob Baker, also died. John Baker lived a few days before succumbing to pistol wounds.

The Ohio River has been at a low stage between Louisville and Pittsburgh for the past few days, and tonnage movements of coal as well as all freights have been light. However, heavy rains over the watershed on Oct. 17 are relieving the situation somewhat.

The Bertha-Consumers Co. has just placed in service three hundred new fifty-five ton, two-door steel hopper railroad cars at its Elsie Mines, Elsiecoal, Ky., on the Louisville & Nashville R.R. The latest improved shaker screen equipment also has been installed at these mines and new houses have been completed to take care of an enlarged working personnel.

The Dixie Gem Consolidated Coal Co., Pineville, Bell County, has increased its capital stock from \$10,000 to \$60,000.

The Kentucky Coke Co., subsidiary of the Louisville Gas & Electric Co., a Byllesby interest, has increased its liability limit from \$500,000 to \$5,000,000. Donald McDonald, Halford Erickson and Matt O'Doherty signed the amendment. The Louisville Gas & Electric Co. interests are installing a new artificial gas plant at Louisville, to start with a capacity of 12,000,000 cu.ft., later to be increased. The company controls its own coal mine at Echols.

The Fordson Coal Co., operating in eastern Kentucky, has asked an injunction to prevent John Colts O'Roake and others of Leslie County, from interfering with surveyors who are running lines on the Ford properties. The surveyors were recently forced to break camp and move on by the hillmen. The suit was filed in federal court at Covington, and a temporary injunction granted. Defendants were ordered to appear in London, Ky., Oct. 18, for a hearing of charges.

It is reported from Jenkins that residents of that town, and the towns of McRoberts, Dunham, Burdine and other operating centers of the Consolidation Coal Co., in the Elkhorn fields, have started a fund for erection of a monument to the memory of John G. Smyth, former company manager, who was killed in a slate fall at Penny, where he held an interest in a small mine he was inspecting at the time. Mr. Smyth was founder of the towns named.

The Clearfield Cannel Coal Co., Clearfield, Rowan County, capital \$100,000, has been chartered by Guy Snyder, G. H. Gearheart, Clearfield; and Drew Evans, of Morehead.

The Dawson Daylight Coal Co., Louisville, will develop 1,400 acres of coal property at Dawson Springs, the contemplated daily output to be 1,500 tons.

The S. & W. Coal Co., Sutton, Pike County, capital \$30,000, has been chartered by J. M. Smith, Uniontown, Pa., and Nora

C. and A. C. Walther, of Sutton. The same interests also chartered the Rockledge Development Co., capital \$20,000.

MASSACHUSETTS

The Island Creek Coal Co. reports for the quarter ended Sept. 30 last net income after taxes amounting to \$623,634, against \$713,154 for the same period last year. After preferred dividends the earnings in the third quarter were equivalent to \$4.61 a share on the 118,798 shares of common stock, against \$5.37 in the same quarter last year. For the nine months ended September 30 last, earnings available for the common stock were equal to \$14.80 a share, against \$20.75 a share in the same period of 1922.

MINNESOTA

The investigation of County Attorney Olson, in Minneapolis, into the coal situation continues to afford the daily papers with considerable copy worthy of headlines. He suspects that the allowance by dealers for loss in breakage of anthracite to be too much, and also sees that there is too much unanimity of prices, although there are some differences. The latest thing to command official attention is the price of coke. The officials of the coking plant were summoned to give evidence. It was claimed against them that they fixed prices because they sent out cards announcing their price, but the answer was that it was purely for advertising purposes. He further complains that coke follows the price of anthracite, although it is made from soft coal. The county attorney believes that the state law against trusts is available.

The Minnesota Securities Commission has revoked the license of the Loudon Coal Mines Co., with an office in Minneapolis, to sell stock in the state. The company was licensed in April, 1920, to sell 2,000 shares of stock at \$50 a share. It is alleged that the company's salesmen have held out an offer to deliver coal at 50c. a ton over the wholesale price, although the company has no yards or facilities for the delivery of coal.

A vigorous campaign is being made against anthracite because of the high price in the Northwest. The Minneapolis Citizens' Alliance, an open-shop association, devotes a portion of its October bulletin to the story of the United Mine Workers, and the recent increase in anthracite, and urges the development of lignite and peat for fuel, in place of anthracite.

MISSOURI

The east side of the Walton coal mine at Higbee was closed down Oct. 1. A total of seventy-nine men were given enforced vacations, which included nineteen company men. There is no immediate prospect of the mine reopening.

Drillers in the big test oil well at Chillicothe passed through four strata of coal one day recently, making a total of 22 ft. passed through in the last 175 ft. of drilling. The various depths are as follows: At 360 ft., the first 6 ft. of bituminous coal; at 378 ft., the second vein of bituminous coal, 3 ft. thick; at 443 ft. a 7 ft. vein of semi-anthracite coal; at 524 ft. a 6 ft. vein of semi-anthracite coal. The geological survey indicates that the coal area in this field extends over 4,000 acres of land and a little over two miles in length.

The Busy Bee coal mine, at Huntsville, which has been idle for a long time, is to be opened after a turbulent time in the courts and elsewhere for the past three years. The plant was sold to Mitchell & Lovell, coal operators of Huntsville, who failed to put the mine in condition to operate because of the opposition of the local miners' union, who demanded that a debt of about \$3,600 for labor be paid. This was not done and the mine remained idle. Recently W. E. Mitchell purchased the interest of his partner, Al Lovell, in the mine and lease of coal. Mitchell subleased the mine to Walter Winkler and Sam Skaggs, experienced miners, and they will operate it on the co-operative plan and run it on the miners' scale. The mine is being cleaned and repaired and is expected to be in operation in 30 days.

The body of Ernest R. Sweeney, of the Gray-Bryan-Sweeney Coal Co., of Kansas City, was found in the Missouri River lodged in underbrush near the bank, not far from Randolph, Oct. 16. Mr. Sweeney disappeared the morning of Aug. 30. His son a few days later found a note in his father's apartment to the effect that he intended to commit suicide. In it he said he was "tired of living." Mr. Sweeney's act is attributed to ill-health and to worry about his wife, who is in a sanitarium in Colorado.

NEW YORK

The Central Railroad of New Jersey after several tests to reduce the time of transporting coal from the anthracite fields to New York City and points east and also to eliminate congestion at different points, has adopted a schedule whereby a train of coal is transported to Jersey City in practically half the time formerly required. Under the old system when a train left the anthracite fields it was taken to Mauch Chunk or Allentown, where it was sidetracked until another train crew could take it to its destination. This system usually consumed at least twenty-four hours before the coal reached Jersey City. Under the new system one of the new Mikado type engines is coupled to a train of cars at Penobscot averaging from seventy-one to seventy-six coal cars, with a tonnage of from 4,600 to 4,760 and transported through to Jersey City with a stop at Allentown of sufficient time to change the entire crew. The engine remains coupled to the train and makes the entire trip. According to a railroad official the trip is made in a little more than twelve hours. Returning trains averaging from 80 to 120 empty cars are brought back on the same plan as outgoing trains.

The Penn Fuel Co., New York City, in submitting a price of \$4.47 per ton was the lowest bidder in offering to furnish and deliver, alongside vessel New York harbor, 670 gross tons Pool 9 bituminous coal, to the United States Shipping Board. The bids were opened on Oct. 15 and the coal was delivered on Oct. 17. Other bidders were: H. B. W. Haff, \$5.10; Lee Coal Co., \$4.63; Imperial Coal Corporation, \$5.04; Rhodes Fuel Corporation, \$4.68; Seiler Coal Co., \$4.64, and Knickerbocker Fuel Co., \$5.25. On a net ton basis, f.o.b. mines, the prices submitted ranged from about \$1.27 to \$1.97.

R. W. Hopkins, chief fuel inspector for the United States Shipping Board, North Atlantic District, has gone to Europe for a few months for the purpose of investigating the fuel situation.

PENNSYLVANIA

The Philadelphia & Reading Coal & Iron Co. and the Lehigh Valley Coal Co. have announced a 10 per cent increase in wages to their monthly men, including mine foremen, assistants, firebosses and clerks. The new wage dates from Oct. 1.

A. S. Wilson of Southmont, Johnstown, has been appointed general manager of the Eastern division of the mines of the Cosgrove-Meehan Coal Corporation in western Pennsylvania, according to an announcement by H. J. Meehan, president of the corporation. He has been connected with the Cosgrove organization for some years and has been actively engaged in their mining work in both the Western and Eastern divisions. Mr. Wilson has assumed charge of his new duties and occupies offices in the Swank Building in Johnstown.

Nine hundred men at the Central colliery of the Pennsylvania Coal Co. at Pittston went on strike Oct. 18 because the boss fireman at the mine refused to join the union. At the Wright Slope No. 6 mine of the same company, also at Pittston, 150 employees struck because a driver boy, who was employed in Detroit during the recent suspension of mining activities was not given his place on his return.

A permanent organization of The Coal Consumers' Association of Philadelphia was effected on Oct. 9. The primary purpose of the association is to bring about a reduction in the cost of anthracite. It has communicated with President Coolidge and Governor Pinchot. A committee has under preparation a schedule of fair prices.

A new corporation, known as the Chase's Mills Coal Mining Co. has been organized to operate the Chase Mills mine, Tioga County. Officers and directors include Dr. C. N. Bradford, Floyd Crist, Alfred Collins, and Robert Krise, all of Canton. The mine is six miles from Canton. Considerable improvement work was started at the mine.

Officials of District 7, United Mine Workers of America, in an official notice sent to all local unions of the district call for Monday, Oct. 29th, being observed as Mitchell Day. The miners are directed to remain away from work that day. The official call in conclusion makes the following statement: "In the observance of Mitchell Day this year we are reminded that the organization has just achieved one of the greatest victories in the history of the anthracite region and this victory was made possible as a result of united organized co-operating effort and we should reserve in the declaration of Mitchell Day this year to do all in our power to maintain our forces to the highest degree of usefulness to the end that in the future we

may continue to write progress into the history of the United Mine Workers of America."

The following plants in the Connellsville coke region have recently closed down: Waltersburg Coke Co., one plant of the Westmoreland-Fayette Coal & Coke Co. and some of the plants of the Consolidated Coke Co., the two latter being in the Pt. Marion-Masontown section. The Pittsburgh & Erie Coal Co., Braznell mine, on the edge of the coke region a couple miles from Brownsville, which had been working steady till last week, is now running on time. The Lilley Coal & Coke Co., following the strike, recently reported, has decided not to make any attempt to start up in the near future, owing to the dull condition of the coal market. This is a union mine near West Brownsville, in Washington County, and on the Monongahela River.

Just when Governor Pinchot will be ready to call a conference of the Governors of anthracite-using states he is not yet ready to say. Prior to leaving the Capitol at Harrisburg for the annual conference of all the Governors at West Baden, Ind., he said he has not yet all the data on the coal situation in Pennsylvania he desires. The Governor suggested the conference to discuss means of keeping down the retail price of coal.

Stockholders of the Reading Co. at a special meeting on Oct. 15 held at Philadelphia, authorized the officers to carry into effect the third modified plan decreed by the United States District Court, to segregate the various properties controlled by the company. Authorization also was voted to increase the indebtedness of the company to the extent of \$64,000,000, the creation of a mortgage and deed of trust to secure the issue of bonds, to merge various subsidiaries, and to dispose of the Reading Iron Co., and the Philadelphia & Reading Coal & Iron Co., in accordance with the segregation plan.

Attorneys for 123 coal companies claim that they have reduced tax assessments of County Schuylkill lands \$100,000,000. The reduction is an agreement between the attorneys for the coal companies and the county attorneys that the ratio of real estate assessment is 45 per cent of the full value and not 60 per cent, as heretofore claimed by the county commissioners. As the coal lands cannot be assessed at a higher ratio of value than other real estate, it is apparent that a big reduction has been made. Although attorneys for the county say the reduction is not more than \$45,000,000, even with that the total assessment is now \$375,000,000, having been increased to that point from \$69,000,000, the last previous assessment. Corporation attorneys say the assessment has been decreased from \$420,000,000 to \$320,000,000. The agreement does not halt the hearing, as the most important issue, whether the coal lands have been assessed at market values, is to be determined. The county commissioners deny that any great victory has been won by the corporations and say they have been willing all along to lower their assessment to arrive at a settlement.

Shipments of anthracite during September, 1923, as reported to the Anthracite Bureau of Information, Philadelphia, amounted to 2,194,940 gross tons. Operation was resumed on Sept. 19 and during the ten working days to the end of the month there was a daily average shipment of 219,490 gross tons. This daily average could have been materially increased had the collieries resumed full operation on Sept. 19. Some, because of an insufficient force of men, did not resume operation until a later date. The average daily shipment during the preceding month of August was 247,105 tons. Shipments by originating carriers were as follows:

	September 1923	August 1923
Phila. & Reading.....	420,859	1,277,770
Lehigh Valley	372,997	1,154,004
Jersey Central	154,200	496,725
Del. Lack. & Western...	318,182	1,004,507
Delaware & Hudson...	298,775	943,143
Pennsylvania	196,839	555,064
Erie	251,277	759,711
N. Y., Ont. & Western...	61,229	154,586
Lehigh & New Eng....	120,582	327,345
Totals	2,194,940	6,672,855

Solution of the recurring coal disputes lies in the direction of better organization in the industry and the working out of an agreement between the coal operators and the mine workers by which the responsibility for establishing and maintaining peace in the industry is recognized and placed upon permanent committees made up of representatives of operators and miners, according to Dr. Royal Meeker, State Superintendent of Labor and Industry. "Public ownership or operation of the mines offers no hope of a

solution in the near future," he said, "because neither the public nor the mine owners are ready for this step. The business of digging, transporting and marketing coal is a very complicated one, and it would require many years to educate the public, the mine owners and mine workers for such an enterprise and to build up a public agency which could conduct this business efficiently, even if it were possible to divorce it from the curse of political appointments and political pressure. Eventually, it is probable, we will come to public ownership and operation, but what is needed is stabilization of the coal industry during the period of education and training requisite to the successful operating of the coal industry by the public."

WEST VIRGINIA

With the end of the first week of October a total of 1,518,000 tons of coal had been consigned from northern West Virginia points to the lakes and it is now estimated that if the average prevailing during the season is maintained the total will reach 1,900,000 tons before the end of the lake period for navigation. Not less than 30,000 cars of coal have been shipped from mines on the Monongah Division of the Baltimore & Ohio and from mines on the Charleston division of the same road even so far this season. There have been shipped from Scotts Run territory about 4,777 cars. Virtually twice as much tonnage has been shipped to lake piers as during any other recent lake season.

A special committee has been delegated by the Kiwanis Club of Beckley to urge the commission recently appointed by Governor E. F. Morgan of West Virginia to select Beckley as the proper place for the location of the recently created School of Mines of West Virginia. The committee is composed of E. L. Ellison, J. Q. Hutchinson and the Rev. W. R. Lloyd. Although replies to communications addressed to the members of the commission have been of a non-committal nature the promise has been held out that Beckley would be considered in connection with the selection of a site.

Millions of dollars collected by the United States Government on the payment of taxes from royalties on coal leases executed prior to March 1, 1913, may have to be refunded as the result of the suit of the Thacker-Pocahontas Coal Co. of Welch, against Albert B. White, collector of internal revenue for West Virginia. This company asks the refund of \$6,000 paid in income tax on royalties received. The case was argued at Huntington in the U. S. District Court for the southern district of West Virginia before Judge George W. McClintic. It is planned by each side to carry the case to the U. S. Supreme Court in the event of an adverse decision in the court below. The coal lease involved in the suit was executed by the Thacker-Pocahontas company in 1901. The argument advanced by the company is that the lease really constituted "a sale of the coal in place" and that it was made prior to March 1, 1913, when the income tax law became effective and that the royalties received are deferred payment for the coal sold under the lease, and if that be true the royalties received are not taxable. Representatives of the government contend that the lease is in the same form which is in general use and does not constitute a sale. It also is asserted by the plaintiff company that if it be held that the royalties received are not to be considered as deferred payments, then enough has not been allowed for the depletion the mining of coal involves.

Coal-loading records for any six-day period in the history of the Chesapeake & Ohio R.R. were exceeded during the week ending Oct. 13, when 17,605 cars were loaded and moved from the Logan, New River, Kanawha and Kentucky fields. The previous record was 17,489 cars during the week of Sept. 29.

The records of the West Virginia Compensation Commission go to show that there is not as much hazard to the coal industry in West Virginia as there is in connection with other industries; the hazard about which so much is heard seems to be more imagination than fact. In short though 60 per cent of the wage earners of the state are connected with the coal industry yet that industry has only 40 per cent of the accidents in the state. Of course the records of the Compensation Commission, being official, effectually dispose of the fiction that there is more danger attendant upon the occupation of mining than in any other occupation. It also is shown by the records that out of the 40 per cent of injuries reported, those peculiar to the mining of coal constitute a still smaller percentage of the whole. The fact that the hazard involved in the mining of coal has been reduced in West Virginia is due partly to drastic laws on the subject and to the education of

miners in safety methods and first aid work under the supervision of the West Virginia Department of Mines which is constantly striving to reduce the hazards.

Four of the six mines of the Cannelton Coal Co. near Montgomery, have been forced to close down due to the dormant demand. The mines just closed are among the largest mines operating on the Kanawha & Michigan.

The White Oak mine, on Jumping Branch in Summers County, is undergoing development and a small tonnage of coal has been produced at this mine recently.

There is a possibility that development of coal underlying the lands of the New River Coal & Land Co. opposite Hinton will be undertaken in the near future. At least plans are being made with that end in view.

Charles C. Dickinson, president of the Dry Branch Fuel Co., was seriously injured in Charleston, Oct. 18 when he was struck by an automobile. The machine struck him as he was crossing the street. His left arm was broken just below the shoulder. In addition he suffered the fracture of both bones in the left forearm. He is cared for at the Kanawha Valley Hospital.

At a special receiver's sale the operation of the Fort Defiance Coal Co. near Kanawha Falls, in the Fayette County field, was sold to Eben M. Martin, the purchaser obtaining the property for the sum of \$2,602. It was necessary, however, for the purchaser to assume the payment of delinquent royalties, which will reach a total of \$5,000.

Edgar Combs placed on trial in Logan County Oct. 15, charged with having participated in the armed march of 1921 against Logan and more directly with having fired the shot which killed Deputy Sheriff John Gore, of Logan, entered a plea of guilty Oct. 17 after the court had denied a request for a change of venue and after C. J. Van Fleet, who has been counsel for the union miners in all the other cases growing out of the armed march, had retired from the case. Two days were consumed in arguing on a motion made by Van Fleet for a change of venue, his plea being that Combs could not obtain a fair trial. Affidavits were submitted by the prosecution to show that Combs could and would receive a fair trial. It also was pointed out by counsel for the state that in every instance where there had been a change of venue, by propaganda and otherwise the union had sought to influence jurors in advance. When Combs indicated to his attorney that he desired to plead guilty, Van Fleet withdrew. The plea of guilty was made with the understanding that a life sentence instead of the death penalty would be concurred in by the prosecution. As soon as Combs had made his plea the court imposed the life sentence upon him.

WASHINGTON, D. C.

During September the Geological Survey made reports on 23 applications for coal prospecting permits and 23 applications for coal leases, under the Leasing Act of Feb. 25, 1920. Since the passage of the leasing law a total of 1,153 applications for coal permits and 411 applications for coal leases have been reported on by the Survey.

C. Lorimer Colburn, of the U. S. Bureau of Mines has succeeded E. H. Denny as secretary of the Joseph A. Holmes Safety Association. Chapters of the association were recently instituted at West Terre Haute, Ind.; Barton, Ohio; Rayland, Ohio; Staunton, Ill.; and New Philadelphia, Ohio.

The Interstate Fuel Co. and the White Ash Coal Co., both of St. Louis, Mo., are named as respondents in a complaint issued by the Federal Trade Commission. The concerns are engaged in the business of buying and selling coal in wholesale and retail quantities, and are charged with the use of the words "Mt. Olive," "Mt. Olive Grade," and "Guaranteed Mt. Olive Coal" in connection with coal from districts other than the Mt. Olive district, sold by respondents in competition with coal mined at Mt. Olive, Ill. The Commission alleges that respondents' coal sold under such names is not the product of the Mt. Olive mine or of the district understood by a substantial part of the purchasing public as the Mt. Olive district. It is also alleged that the company's acts are unfair to competitors who actually deal in Mt. Olive coal.

Argument has been heard in the U. S. Supreme Court in the case of the Matthew Addy Co., coal dealers of Cincinnati, charged with violating the Lever fuel-control law by selling coal at a margin of 25c. per ton as against a margin of 15c. established by the government during the war.

CANADA

The provisional officers of the United Mine Workers of District 26, have sent a communication to the Dominion Coal Co. asking that a date be set for a conference to discuss a new wage contract, and suggesting Tuesday, Nov. 20, as a date suitable for the first meeting. If this is not agreeable, any other day could be mutually arranged. The present working contract between the miners and operators expires on Jan. 15 and under the agreement it is necessary that if either party to the agreement desires a change, they must give 45 days notice in writing of such desirability. It was said that the miners will demand a restoration of the 1921 rates, and some readjustments in several classes. Phalen local at No. 2 is the first of the U.M.W. locals to take a stand on what they want in a new contract. They have passed a resolution, that is being forwarded to all other locals in the district, asking for a 40 per cent increase over the present rates, which is equivalent to 20 per cent over the 1921 rates.

The eighth annual field day of mine-rescue and first aid competitions of the Vancouver Island Mine Safety Association was held at Ladysmith, B. C., on Sept. 3. There were nine entries for the mine rescue event for the V.I.M.S.A. shield and individual prizes. After a close struggle the shield was won by No. 7 team, Captain Williams, of Cumberland, with 93.2 per cent; second place by No. 3 team, Coal Creek, Captain Caulfield, with 93 per cent, and third place by No. 5 team, Captain Broderick, Nanaimo, with 89.4 per cent. In the first-aid events the British Columbia Mines Department Cup was won by Nanaimo, Captain Barton's team; Captain Beveridge's team, Cumberland, being second. There were eight entries. The W. L. Coulson Cup was won by Captain Beveridge's team, Cumberland, with Captain Delaney's team, of Ladysmith, second. There were eight entries. For the one-man event there were nine entries, and J. Thompson and J. Scott (patient), of Nanaimo, took first place, and H. M. Yeowat and A. Inayh (patient) second. In the two-man event J. B. Stewart's team, of Cassidy (Granby Consolidated L. & P. Co.), was first, and Thorpe's team, of Nanaimo second. The V.I.M.S.A. Junior Challenge Cup was won by Captain Wharton's team, Nanaimo, with Captain Wilson's team of Ladysmith, second. The V.I.M.S.A. Ladies' Challenge Cup was won by Mrs. Henderson's team, of Cumberland. Second place was won by Mrs. Delaney's team, of Ladysmith, and Mrs. Rutherford's team, of Nanaimo, won third.

Ross C. Wheatley, of Hamilton, Ont., has been appointed Canadian representative of the Maher Collieries Co., of Cleveland, Ohio, which will open offices in Hamilton about the beginning of 1924.

Dan Livingstone, James B. McLachlan and others of the deposed United Mine Workers' executives in District No. 26 had their legal status restored on Oct. 9, when Justice D. D. McKenzie, in the Supreme Court, at Sydney, N. S., granted an order discharging and vacating the restraining order which Silby Barrett, provisional president, obtained from Justice Chisholm in Halifax July 23. This restraining order prevented Livingstone, McLachlan and the various district board members, from functioning as U.M.W. executives and also prohibited them using certain moneys, then on deposit in the banks to the credit of the U.M.W. in District 26. N. R. McArthur, solicitor for Barrett and President John L. Lewis, announced that he had filed a discontinuance of the order and would not take the action to trial as proposed.

MEXICO

Alexander V. Dye, of New York City, an experienced mining man, has been appointed commercial attaché of the Department of Commerce at Mexico City, it has been announced by Secretary Hoover. Mr. Dye is a native of Flora, Ill., and a graduate of Williams Jewell College and of the University of Leipzig. He is intimately acquainted with Mexican economic conditions, having served as United States Consul at Nogales from 1909 to 1913. Mr. Dye served as assistant general manager of the Phelps Dodge Mining Co. of Arizona several years. During the war he was war trade representative at Christiania, Norway, and was European representative of the American International Corporation 1919-21. In September, 1921, he was appointed a trade commissioner of the Department of Commerce and assigned to the American Embassy at London. He sailed from London Oct. 17 and after conferring with the Department of Commerce officials in Washington will proceed to his new station at Mexico City.

Obituary

Byron F. Hobart, 76, once president of the Kansas & Texas Co., died Oct. 3 in San Diego, Cal. Mr. Hobart had lived in San Diego since 1914. He long ago sold his coal interests to Richard Keith of Kansas City. He retained large properties in Missouri and was president of the Union Iron Works, of Springfield, Mo. He was the first president of the San Pedro, Los Angeles & Salt Lake Railroad Co., but retired from all business activities when he went to San Diego.

Frederick Rheinfrank, 62 years old, senior vice-president of the Stokes Coal Co., New York City, died Oct. 15 after an illness of several months. He was born in New York City and had spent most of his life in the coal business. He formerly was head of the J. Rheinfrank Company, which was absorbed by the Stokes interests a few years ago. He was a member of the Uptown Club, the New York Athletic Club and several other organizations. He leaves his wife, Mrs. Mary Louise Rheinfrank.

Thomas Ward, 82, retired coal dealer, died Oct. 18 in his home, 596 West 152d Street, New York City. He was born in County Wexford, Ireland, and came to New York in 1866. After being on the police force for a short time he entered the employ of Townsend & Co., coal dealers, and in 1888 he purchased the business and conducted it as the Thomas Ward Coal Co. In 1908 the business was turned over to his sons, Joseph, William, Thomas and Walter, and he had since devoted his time to real estate operations, having acquired holdings in the Washington Heights section. Besides his wife and sons he leaves a daughter, Mrs. William J. Hammer. Funeral services were held at 10 A. M., Oct. 20, in the Church of St. Catherine of Genoa.

Profound regret was caused by the death at Fairmont, W. Va., on Saturday, Oct. 13, of **A. Brooks Fleming, Sr.**, one of the grand old men of the state, long a leader in its industrial, commercial and political life as well as a leader at the bar and at one time the Governor of West Virginia. At the time of his death former Governor Fleming was in his 84th year. Until within the last few years he had continued in the active practice of law and had also devoted much of his attention to the many mining properties in which he and members of his family were interested, having played an important part throughout his long and useful life in the coal development of northern West Virginia. He married Miss Caroline Margaret Watson, daughter of the late James O. Watson, a pioneer in the mining industry in northern West Virginia, with whom Governor Fleming was actively associated in the coal business. His wife is a sister of Colonel Clarence W. Watson, president of the Consolidation Coal Co. She survives him in addition to four children: Mrs. Charles E. Ward, of Charleston, W. Va.; Mrs. Charles B. Mitchell, of Fairmont; George W. Fleming, of New York, president of the Elkhorn Coal Corporation, and A. Brooks Fleming, Jr., who is assistant to the president of the Consolidation Coal Co. For many years Governor Fleming was counsel for that company and other large companies in northern West Virginia, and a director in the Consolidation company. The funeral was held at Fairmont Oct. 15th and was attended not only by many distinguished citizens of West Virginia but by many coal men from New York and other important coal centers.

Thomas Cunningham, county mine inspector of Madison County, Illinois, died recently at his home Edwardsville, Ill. The County Board of Supervisors has appointed a man under the emergency act to fill the place until Dec. 1 when the term of Cunningham would have expired, at which time a regular appointment will be made. The duties of the officer is to inspect reports of deaths, injuries and accidents at the mines.

Association Activities

Transportation problems were paramount at the regular monthly meeting of the **Smokeless Coal Operators Association of West Virginia** held in New York about the middle of the month. In calling the meeting to order President Robert H. Gross made feeling reference to the recent death of Kuper Hood. A committee consisting of T. F. Farrell, O. M. Deyerle, G. H. Caperton, W. P. Slaughter, George Daniels and T. S. Crockett was appointed to prepare suitable resolutions of respect covering the death of Mr. Hood. There was discussion of the position taken by coal operators north of the Ohio River that the coal fields of West Virginia are "children born before their time" and of the activities of operators in the Pittsburgh district in filing their petition before the Interstate Commerce Commission asking that the freight rates on coal to the lakes and Northwest as to differentials against West Virginia be still further widened, all of which were considered as being of vital importance to the coal industry of the entire state.

Traffic News

The railroads during the month of September placed in service 18,519 new freight cars, together with 380 new locomotives, according to the Car Service Division of the American Railway Association. This brought the total number of new freight cars installed from Jan. 1 this year to Oct. 1 up to 134,636, while the number of new locomotives installed during the same period totaled 2,963. The railroads on Oct. 1 also had on order 64,601 new freight cars, with deliveries being made daily. They also had 1,242 new locomotives on order. Of the new freight cars installed during September, 8,916 were coal cars, which brought the total number of cars for that class of equipment installed during the first nine months this year up to 55,575.

According to information the October report of the D. L. & W. Ry. should show the highest car loadings for the current year. For the first thirteen days of this month loadings of anthracite on Lackawanna's lines amounted to 415,690 tons, as compared with 389,410 tons for the same period last year. Bad order cars as of Oct. 12 amounted to 3.68 per cent of the total on line, while locomotives out of commission represented 16.16 per cent of the total on line.

W. J. Manley has resigned as traffic manager of the Logan Coal Operators' Association after three years' service with headquarters in Washington, to take a position in the traffic department of the Pittsburgh & West Virginia Ry. and West Side Belt R.R. at Pittsburgh.

Complaint has been filed with the Interstate Commerce Commission by Smith & Duckworth and Joseph Dinford & Son, against the C. C. & St. L., and others, alleging violation of the Transportation Act in the rate of \$1.40 a net ton charged on bituminous coal from points in the Clinton and Brazil districts of Indiana to Crawfordsville, Ind., and other Indiana districts via interstate routes. Nine similar complaints were filed by other consignees, alleging unjust discrimination with respect to Indiana rates.

The Car Service Division of the American Railway Association announces that the locomotive equipment of the railroads of the United States is now in the best condition it has been in years. The railroads of this country on Oct. 1 had 9,823 locomotives, or 15.3 per cent of the total number on line, in need of repair. This is the smallest number in need of repair

for any period since the Car Service Division began the compilation of these records in August, 1920. This also is a decrease of 969 locomotives compared with the number in need of repair on Sept. 15, at which time there were 10,792, or 16.8 per cent. The railroads on Oct. 1 had 54,159 serviceable locomotives, an increase of 892 compared with the number serviceable on Sept. 15. They also had on Oct. 1, 2,620 locomotives in good repair but in storage.

Suggestion that freight rates on anthracite to Canada be the same as those to northern New York and New England has been made by President Coolidge to President Rea of the Pennsylvania R.R. It is said that the fact that coal is shipped to Canada at lower freight rates than for domestic consumption in the United States is a source of complaint in New England.

The Interstate Commerce Commission has given notice that the case of the **Northwestern Coal Dock Operators' Association vs. the Chicago & Alton R.R.**, Docket 14476, has been assigned for hearing and before the full commission, Nov. 15, 1923, at 10:30 a.m., in Washington. This case also includes Docket 14533. Traffic Bureau of the Sioux City Chamber of Commerce vs. the Baltimore & Ohio R.R.; Docket 14622. Board of Railroad Commissioners of the State of South Dakota vs. the Chicago & Alton R.R.; Docket 14142. Illinois Coal Traffic Bureau vs. the Chicago & Northwestern Ry., and Docket 14477. C. Reiss Coal Co. vs. Ahnapoe & Western Ry. Among other matters, the case involves dock rates on coal vs. all-rail rates.

Freight traffic during the first eight months this year was the heaviest in the history of the United States, according to reports by the Bureau of Railway Economics, amounting to 304,267,000,000 net ton miles. This was an increase of 3.6 per cent over the corresponding period in 1920, which marked the previous record and 5½ per cent greater than the first eight months in 1918, when freight traffic was greatly stimulated by the war. Compared with the first eight months last year, when freight traffic was reduced somewhat not only by the strike of coal miners but also by that of the railway shopmen, freight business from Jan. 1 to Sept. 1 this year was an increase of 33½ per cent. The average load per car in August was 28½ tons, the same as in July. This is the highest average for any August since the compilation of these records was started in 1917, except in 1918, when the average was 30.1 tons and August, 1920, when it was 29.8 tons. The average daily movement per freight car during August was 28.2 miles, which was an increase of two-fifths of a mile over that for July this year and the highest for any August since the compilation of these records began, exceeding by four-fifths of a mile the average for August, 1920, and by 2½ mile the average for August, 1918.

The receiver of the **Denver & Rio Grande Western R.R.** has asked the Interstate Commerce Commission for permission to acquire the line of the **Alamo Coal Co.** connecting its mine at Alamo, Colo., with the applicant lines at Kebler, in Huerfano County, Colo. The coal road is 4.18 miles in length and in addition has tippie, passing and storage tracks approximating 1.65 miles in length. The consideration is to be \$80,000. It is stated to be uneconomical for the coal company to equip and operate this trackage, which would put it at a disadvantage in competing with other coal mines in the Walsenburg district.

Freight cars in need of repair on Oct. 1 totaled 151,332, or 6.7 per cent of the number on line, according to a report by the Car Service Division of the American Railway Association. This is a decrease of 13,952 under the number in need of repair on Sept. 15, at which time there were 165,284, or 7.3 per cent. Freight cars in need of heavy repair totaled 118,563 or 5.3 per cent of the number on line, which was a decrease of 11,549 compared with the number on Sept. 15. Reports showed 32,769, or 1.4 per cent, in need of light repair, a decrease of 2,403 within approximately 15 days. This is the best condition of railway freight cars that has existed on the American railroads for years.

Coming Meetings

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, Editor

Volume 24

NEW YORK, THURSDAY, NOVEMBER 1, 1923

Number 18

Dividing the Spoils

ANTHRACITE mine workers are complaining that since they got their 10 per cent wage advance, their landlords have been raising rents, barbers charging more and the cost of living generally has been going up for them. It is not surprising that these beneficiaries of Governor Pinchot should complain that they are being called upon to share their gains and thus to increase the prosperity of their home towns. It would have been surprising indeed if the merchants and landlords had not set about to garner to their coffers as much as possible of Pinchot's \$40,000,000 gift.

We shall await with interest to learn whether Mr. Pinchot, having been notified that other citizens of Pennsylvania have taken to themselves the 10 per cent increase he gave the miners, will then call in the operators and announce that another increase is justified, due, and must be forthwith granted.

Do Strikes Pay?

DESPITE the five months' strike the production of bituminous coal in 1922 exceeded that of 1921 by more than 6,000,000 tons, and the average number of days worked the country over was 142, only 7 days less than the 149 in 1921. More tons in less days meant more men. The net gain in men employed—from 663,700 in 1921 to 687,900 in 1922—was 24,200.

Compared with 1921, Illinois last year lost 11,000,000 tons of coal output, followed by Ohio with a drop of 5,000,000 tons, Pennsylvania with 3,000,000 tons, Wyoming and Indiana with about 1,000,000 each, and Kansas and Missouri with losses between 500,000 and 1,000,000 tons. The total of these is about 22,500,000 tons.

Turning to the gains, which were in the aggregate sufficient to overbalance the strike losses in other fields and add 6,000,000 tons, we find Kentucky leading with 10,000,000 tons over 1921, West Virginia with 8,000,000, Alabama with 6,000,000, Virginia with 3,000,000 and Colorado and New Mexico with nearly 2,000,000 between them. There was little difference in output in the two years in Iowa, Montana, Maryland, and some other states.

Alabama employed 2,000 more men; Kentucky, 10,000; West Virginia, 8,000, and Virginia, 1,000 more than 1921. The men in Alabama worked 49 more days than in 1921, those in Virginia 32 more, but the greater number of men in Kentucky worked 12 less and in West Virginia 6 less on the average than in 1921, when there was no general strike.

It is perhaps surprising that all the furor of the big strike of 1922 had no greater influence in price than is shown by the figures for average realization published by the Geological Survey. The average value per ton of all bituminous coal at the mine in 1922 was \$3.02, a gain of 13c. over 1921. Kentucky received an average

of 33c. per ton more than in 1921; West Virginia 9c. more. Alabama coal averaged 74c. less per ton and Virginia coal 48c. less in the strike year than in 1921.

Thus the big strike brought more mine workers by the thousands into the soft-coal industry, all in the non-union fields, where the expansion was possible. It proved no bonanza period for the non-union producers as a whole, for with prices held down and no more opportunity to work than in as dull a year as 1921 there was little of the golden opportunity that is supposed to confront them when the union mines are on strike. Of course it must be remembered that the railroad men in the South were on strike if the coal miners were not, and this affected the returns for 1922 to a certain extent.

Spuds

THE world is small after all. Here is the farmer whose woes are concerning the politicians—he has trouble with the price of wheat, the boll weevil, and now we learn that with potatoes all is not well. Some seventy million bushels of potatoes rotted in the ground, undug, last year. Yet, according to the *Country Gentleman*, only a normal number of bushels reached the market, at prices particularly ruinous to the individual grower. This publication for the dirt farmer goes on to say that those undug potatoes—and the farmer—broke the market. Spurred on by rumors that there was a general overproduction he hastened his digging and by his very energy in getting them on the market, broke prices so that it did not pay to dig the rest. No matter how low the price, there is a limit to the bushels of potatoes the country will buy and use.

This country is saturated with soft coal. Stocks are abnormally high. The mines have been kept in operation throughout the summer and the price each week has slumped lower. What is breaking the price? Why is it that last week the Shipping Board was offered 1,800 tons of high-grade low-volatile coal at \$1.02 per net ton at the mines—coal that doubtless cost nearly \$3 per ton to produce?

The answer is the same for potatoes and coal—more produced than required. The farmer who this year lost money on potatoes may turn to another crop next year and make a profit. The coal operator who in such a market digs coal and ships it unsold is more foolish than the farmer because the coal will not rot if left in the ground for another season—that is to say more foolish unless he is consciously riding the market down in the hope of proving a better stayer than some other fellow and thus testing out the theory of the survival of the fittest.

We believe it is an idle dream to imagine that the farmers can ever be brought to the point of sowing a crop to fit the market, no more, no less, if for no other reason than because no one can ever gage in advance the requirements accurately. Nor can we ever reach such

perfection in coal-mine capacity and production that we may foresee and entirely forestall "no bills" and distress coal on the one hand and panic prices on the other.

If the farmer will read the signs of the times and act concertedly he may help himself—so may the coal operator when he gets the same treatment under the Sherman Law.

Regulation of the Consumer

COAL salesmen who have trouble disposing of small sizes may look forward to the day when they may take the attitude displayed by the operators of the "Coal River Collieries." This company, it will be recalled, is the Brotherhood of Locomotive Engineers and has mines in West Virginia and western Kentucky. The stock in this enterprise is owned by members of the organization and the company specializes in car-lot sales of coal to its stockholders. This is excellent, for it is effectual education for these men in some features of the coal business.

For instance, in the October issue of the *Locomotive Engineers' Journal*, Grand Chief Engineer Stone advises that much confusion and dissatisfaction is caused by the invariable demand for lump coal, "the very highest price coal there is." He urges that run-of-mine is the best, costs \$1 less per ton, but that "if you must have lump coal, then order egg or nut size, which is still cheaper than the large lump coal." His argument is that "if you follow these suggestions, you will burn less fuel, have more heat, and save a big percentage in the cost of your fuel bill. Try it once and be convinced."

If commercial operators could tell their customers, "If you must have lump, order nut or egg," a part of their troubles would be over. That is regulation of consumption and would follow, as the night the day, any regulation of coal production and distribution.

The Perennial Optimist

SOMEONE has said that the surest way to go broke is to "go short" on the United States, which is but another way of saying that the upward surge of business and industry in this country has always overcome temporary depression and mounted yet higher. In his annual address to the American Iron and Steel Institute last week Judge Gary again gave utterance to his unflinching faith in prosperity. He always manages to see the bright side of things, and who will venture to say that his predictions have not proved his wisdom?

"It may be stated with confidence that the outlook is good," he says this year, and if the outlook is good for iron and steel it must be good for coal in so far as tonnage is concerned. According to Judge Gary, the iron and steel industry will show considerable profit this year, though not as much as the capital invested should produce. This is not what the coal industry has to show for this year, despite the excellent showing on production. The hard-coal branch is the better off, as prices have been sustained at a profitable level, strike losses in September being the only detracting factor.

The soft-coal industry, however, has poured coal onto the market at continually lowering prices and the average return has not been remunerative, though many companies have had a good year. The prediction that business is not going to pot because of Europe's troubles and that the outlook is good will hearten those in the

coal trade who are hanging on by a thread, for a continuation of present conditions will weed out the weak and in the end produce a healthy trade for those fitted and equipped to survive.

Culpable but Not Criminal

IT IS easy to understand why the Coal Commission displayed such choler in its report on the wholesale coal trade. Its investigations brought to light the intimate details of a series of deals in which coal, notably anthracite, was passed from hand to hand at increasing prices and by those who made serious attempts to conceal their activities. There is nothing to be said in extenuation, for instance, of the resort to split commissions as a method of getting round the prices set in the gentlemen's agreement known as the Pennsylvania Fair Prices of 1922. The best that can be said for those who sought to reap large profits by diverting company coal at premium prices and otherwise indulging in "backdoor" selling of coal is that they violated no law.

The crux of the whole matter is that the Commission, finding such plain evidence of extortion, waxes exceeding wroth because it could lay its hand on no panacea for this evil. It unfairly ties its recital of these abuses onto its story of the coal wholesalers and thus indicts that branch of the coal industry. Its own evidence includes producers, wholesalers and retailers equally in nearly every citation of pyramided prices. It is in the exercise of the middlemen *function*, no matter by whom performed, that these shady practices are found.

This report of the Coal Commission is not, however, wholly unfair to the wholesale coal trade, even though it smacks of the universal prejudice against middlemen. It had the facts from the books of the companies with respect to costs, income and profits. Its report is built around these bookkeeping facts. It finds that "even though the wholesaler normally operates at a fair margin and carries on an essential distribution service respecting a considerable part of the nation's tonnage, his speculative activities in times of shortage have been one of a number of causes of public unrest and dissatisfaction respecting the coal business." This is a back-handed way of saying, as is stated with respect to the retailer in the same report, that "In general the competitive nature of the retail trade makes regulation of margins and prices unnecessary except in cases of emergency shortage." This is equally true with regard to the wholesaler and the producer—and the consumer, although the Commission omits that reference.

Now, of course, the obvious thing to do is to attack the problem at its source—to eliminate the shortages—which is to say, cut out the large-scale strikes. But that is too simple in theory and too difficult in practice to intrigue the intellects of those who would reform coal. It is idle and even silly to level criticism at the Coal Commission for gathering and publishing facts or to condemn the collection of data in the report on the wholesale coal trade just because it discloses the indulgence by a few in unmoral tactics, the recital of which strikes a popular chord.

The coal trade may well consider in advance the effect on the incoming Congress of this angle of the Coal Commission's work fortified weekly by assaults from the Federal Trade Commission. Here is something that will appeal to demagogic congressmen and furnish inspiration and material for a flood of oratory, as it has already of press comment.

*Blocking a Car in Anthracite Breast**

Changes in Design of Mine Cars Made Necessary by the Substitution of Mechanical for Animal Haulage[†]

Rigid Trucks Reduce Derailments—Omitting Washer May Wreck Car—Should Brakes Be Provided?—Mis-shapen Cars Run Foul of Timbers—Should Make Car Irons of Wood Cars Excessively Heavy

BY G. M. GILLETTE[‡] AND J. W. REED[§]

SAFETY in mine-car construction and maintenance is such a broad subject and involves so much detail that in an article such as this it is possible only to call attention to those facts which seem to stand out most prominently.

The thickness of the seam of coal and the method of mining restrict the width and height of mine cars, and the size of the shaft limits their length. These dimensions enter materially into the safety of the car, but we cannot alter these conditions and must use the size which permits us to get out our coal most economically, accepting these restrictions as we do natural hazards such as bad roof.

The design of bumpers, couplings, running gear and body, however, are features which may be modified, and the safety of their construction, therefore, is open to discussion. The coal-mine car is, and has been for

the past ten years, undergoing reconstruction in order to meet the new requirements of electrified mines. Undoubtedly many of our haulage accidents are traceable to the use of a car designed primarily for mule haulage which, with little or no change, has been pressed into service with gathering motors.

The new requirements are that the car be capable of being pushed ahead of the locomotive around sharp curves and be able to withstand more abuse and higher speeds than the mule-drawn car. Safety in present-day mine cars is largely a matter of mechanical strength. Their axles and wheels must above all remain rigid. A flimsy car or even one in which the wheels are merely out of line will cause many derailments.

BOLTING AXLES TO CAR BOTTOM INADEQUATE

The means of fastening the axles to the car body therefore is most important. The axles must not be merely bolted to the car bottom. It is necessary that they be reinforced and braced from axle to axle in order that they may be held rigidly in place, and it is better yet to fabricate or weld these braces and the axles into a truck of all-metal construction and then fasten this truck as whole to the car body and drawbar.

Lubrication is important, and roller bearings, grease or oil arrangements by which a constant supply of

*The headpiece shows method of blocking car by a post resting against a tie in the room track. This may not prove a sure anchorage and the prop may fall. Consequently a block is set on the rail and secured by a clevis, a chain leading from the clevis to the car hitching, to which it is attached by a hook. Should prop and block fail the chain would act. A small prop sprag has been placed under the front wheel.

†Article entitled "Safety in Underground Transportation in Coal Mines—Mine Cars," read before the National Safety Council at its Buffalo meeting, Oct. 4, 1923.

‡General manager, Consolidation Coal Co., Frostburg, Md.

§Safety director, Consolidation Coal Co., Fairmont, W. Va.

TWO-BUMPER ENDGATE CAR AT AN ANTHRACITE MINE

In the anthracite region, mules and short locomotive trips are still not uncommon. Conditions in many anthracite mines do not favor the storage-battery locomotive and the long trips that are so general in bituminous-coal mines. Consequently the double bumper and endgate have not found so much opposition from mining engineers in the hard-coal region as in soft-coal districts.

lubrication is furnished the wheel, decrease the wear on the axle and hub and help to prevent the wheels from becoming wobbly. But of even more importance than lubrication is that the wheel be so designed that the hub and axle shall wear evenly. The weight of the car must rest squarely upon the hub bearing. When it fails to do this, the hub will quickly wear conical, causing the wheel to become wobbly. To produce an even wearing of the hub and axle the center of the line where the tread rides the rail must be very nearly under the center of the hub bearing.

In service the wheels always must remain securely fastened to the axle. A washer and cotter key through the end of the axle probably is the oldest and the most common form of fastening. The use of this washer is obligatory as it prevents excessive wear of the cotter key, but unfortunately it frequently is omitted when the old wheels of a car are replaced. Any wheel in which the device by which it is fastened to the axle is not protected against excessive wear is dangerous and one that will be found loose on the axle most of the time. This defect is not confined to the old-style "oil-it-every-trip" wheel, for some roller-bearing and grease-packed wheels have this defect. Many a serious wreck can be traced to such loose wheels, whereas had the wheels been securely fastened the derailments would have been so trifling that the cars could be replaced in a few minutes.

Brakes sometimes are omitted, sprags being used to hold cars on steep gradients. This undoubtedly introduces an extra hazard, and we are disposed to believe that brakes are a necessity in all mines both for safety and efficiency. In a single coal mine brakes of many different designs are commonly found in use. Much might be said for and against almost all of them. The important requirement is that when they are in the off position they must release fully so as not to drag on the wheels and when applied they must put sufficient friction upon the wheels to retard, stop or hold the cars on the grades encountered or as the necessity of the haulage system requires.

Within certain limits the simpler forms of brake riggings are more dependable as they are more easily kept in repair. Of course the brake must be of sturdy construction and to operate satisfactorily it must have

provision for taking up the wear of the band or of the shoes by which the pressure is applied.

With compound-lever action the play in the bearings between the movable parts must be carefully regulated. A little too much play in each bearing means much lost motion when the movement finally reaches the brake shoe, and many otherwise well-designed brakes have failed entirely on account of poorly made bearings. If you are having trouble with your form of brake, study carefully the bearings between movable parts. A more serviceable bearing probably will eliminate most of the trouble. Loose bearings are one of the most common causes of dragging brakes, and of course a brake which always rubs on the wheels usually is worn out and useless when needed.

On light grades the two-wheel brake meets with all the requirements of safety, but on heavy grades the four-wheel brake is almost a necessity.

For safety the brake should be applied either by pulling up or back on a side brake and away from the center of the car with an end brake. All brakes must be operated from the same side, which must be that opposite the trolley wire—that is, on the clearance side of the roadway.

The handle or device for operating the endgate latch should either operate automatically as the car is dumped or else be placed within convenient reach of the man standing alongside the car. To locate it so that the man must step on the front bumper to unlatch the endgate is dangerous.

CAR WITH ENDGATE IS STRUCTURALLY WEAK

Both the swing and lift endgate type of car cause one entire end of the wagon to be left structurally weak and without side support. Only with difficulty is a car of this kind designed with the required rigidity, and it is not easy to construct one that will keep its shape reasonably well after some years of service. The increasing use of rotary dumps, by removing the need for a swinging or lifting endgate, is overcoming this defect and permitting of a much more substantial type of car.

Where the roof is unusually dangerous and where, accordingly, it is necessary to timber close to the track a crooked car is a menace, for the side of the wagon may strike and dislodge such timbers, greatly increasing the dangers of haulage. Anything that makes possible the use of a more rigid car is a step forward in safety. For this reason I look upon the rotary dump or any dumping system which eliminates the endgate as a safety provision.

Car irons, drawbars and the iron ribs of wooden cars must be designed with more than the strength desired for the car when new, it being customary as soon as the wood portions wear out to rebuild the irons into a new car and to continue doing so during the life of the mine, so that the irons in the car usually have the life of a number of mine cars. The rusting and corrosion during the length of service expected of car irons should be taken into consideration in the original design of the car.

The design of mine-car bumpers should be carefully considered if safety is to be attained. The old-style double bumper with a three- to five-link coupling was the natural outcome of years of experimenting in producing a car suitable for mule haulage. It is a good car for that purpose, but with the electrification of the mines and the introduction of gathering locomotives

this type of bumper became unsafe and the cause of numerous accidents. The single and round bumpers designed so that cars may be pushed ahead of gathering locomotives, though they overcome some of the objectionable features of the double bumper, introduce several new hazards which require careful consideration.

Prominent among these hazards with some kinds of round bumpers is the closeness with which the edges of the cars approach each other on curves. When side brakes are provided the brake handle should not protrude past the end of the car. End brakes cannot be applied or loosened from the inside of curves nor can a car with end brakes be coupled safely from that position.

The bumper must be large enough to furnish a good footing for the brakeman riding the rear end of the trip and must hold the cars far enough apart to prevent injury when coupling cars on straight track. The bumpers must be deep enough to prevent them from riding over one another when the cars strike together.

The hole for the removable pin must be made larger through the bumper than through the draw bar so that objects passing through the latter will fall on through and not obstruct the hole. The coupling link should have room back of the fixed pin so that it can slide back clear of the edge of the bumper when cars come together. When two cars are bumper to bumper, 4 or 5 in. of room should be provided between the tops of the clevises holding the link, in order to prevent serious injuries to hands when coupling. The removable pin must be fastened to the car by a chain and should have a wide flange just below the hand hold to prevent the hand of the man making the coupling from being pinched between the pin and the end of the car. The hole for this pin should not be far from the end of the car body.

Much vertical play must be allowed between the link and clevis or when the cars are pushed together the link will bear down upon the end of the next car and raise it off the track at low joints.

As cars vary in capacity from 1,000 lb. to 5 tons or even more, their strength must be calculated for their individual needs. However, within practical limits, if the various parts of the car are made heavier than apparently is required by the strength-of-materials formula, you will have a car more easy to keep in repair, and that means a safer car, for more accidents occur from faulty upkeep than from faulty design.

The following criticism has been made of the state-

CAR BEING OVERTURNED IN ROTARY DUMP

This car has merely a center bumper. Among other advantages of the rotary dump is the fact that with it a car can be made which will keep its shape and not sag down onto the wheels and get out of line, raking props and other timbers and making brakes, where provided, ineffective.

TIPPING OVER A MINE CAR IN SHOP

More attention has been paid lately to the stiffness of the truck. Unless the truck keeps its shape the car will not be safe nor indeed run easily.

ment in this article, "I am disposed to believe that brakes are a necessity in all mines both for safety and efficiency":

"There is a strong tendency now to do away with brakes entirely. With electric haulage and large cars, a car is not supposed to move unless a locomotive is attached to it. In consequence, unless the grades are excessive, the locomotive can apply all the brake power necessary. Most accidents occur by depending on brakes. Frequently these are out of order and a runaway occurs. Better to have no brakes and not depend on them than have brakes that are not dependable."

In replying to this criticism we feel that this is a fact, but we would not recommend dispensing with the brakes at all times. It is most difficult to arrange mechanical haulage so as always to move the car with the locomotive. Though such a manner of operation is possible yet we do not believe it will ever "work out" in the usual system of coal mining.

What is said by this critic about bad brakes also is true, but is this not a question of upkeep, for which the management is responsible? It does not seem that we should abandon the use of a necessary part of the car equipment because its upkeep is likely to be neglected. Should we not aim at eliminating such defects as prevent the brakes from being maintained in proper working order?

Suggestions as to the Construction and Location of Mine Gathering Pumps*

PUMPS for development work should be located in a place temporarily provided as near as possible to the place where the water accumulates but so far away from the haulage roads and working places as not to interfere with mining operations.

For development work, piston and plunger pumps generally are used. For ease in handling, they should be mounted on trucks or skids. They should have a capacity of from twenty to one hundred gallons per minute at 125 ft. total dynamic head.

Where quantities of water in excess of one hundred gallons per minute are to be handled, rotary and centrifugal pumps are used to some extent, and if the volume of water is fairly constant and does not contain too much acid these pumps prove very satisfactory. (This recommendation is noted as being contrary to the consensus of opinion of the convention at Pittsburgh.)

The discharge pipe should be of sufficient capacity that the total dynamic head will not require the pump to exceed its rated capacity. Where small quantities of water are to be handled it is not feasible to use pipe that will resist the corrosive action of acid water. Where larger quantities of water are pumped and the water contains much corrosive acid, it is advisable to use wood or other acid-resisting pipe.

KEEP ACID WATER FROM EXTERIOR OF PIPE

Care should be taken to keep the pipe blocked up from the bottom of the heading or pump chamber so that no acid water or moisture can come in contact with the outside of the pipe. The loss of head due to friction should be taken from the tables in the Hydraulic Society's Report of 1922, pages 16, 17, 18 and 19.

Pump installations for development work are of a temporary character, and they should be installed with that fact in view. The pumps should be so located that they are easily accessible for oiling and repairing and so that the attendant can move about the pumps freely without coming in contact with any of their moving parts.

Large sump capacity cannot usually be provided in practice, but sufficient space for water storage should be obtained so as to keep the pump in as nearly constant operation as possible. The motors for development pumps should be specially built for this class of service, as the standard motor does not give satisfactory results under ordinary pumping conditions. Where direct current is used compound motors should be installed. They usually should receive their power direct from the haulage circuit. Where alternating current is available the ordinary squirrel-cage induction motor proves very satisfactory.

Controllers should be moisture-proof and enclosed, whether they are manually or automatically operated. All coils and resistance should be so constructed as to resist the moisture contained in the mine atmosphere.

All motor windings, including the armature and field coils, should be thoroughly treated with a compound that will resist the action of the acid in the mine water.

Special attention should be given to see that the field coils are entirely saturated with moisture-proof insulated material.

For gathering work, pumps should be selected which will start without priming and will pump air and water alternately in case the suction pipe is not at all times submerged. Pumps should be so constructed that they can be lubricated without excessive waste of oil. In all cases they should be fully equipped with grease or oil cups, whichever is best suited for the bearings. They should be so constructed that the acid water leaking from the packing glands cannot get into any of the bearing surfaces.

Valves should be so constructed that small chunks of coal and any other solid matter such as are constantly being washed into the sumps will go through them without clogging. Valves should be readily accessible for cleaning in case they become clogged.

PLUNGERS SHOULD NOT CORRODE, SCORE AND WEAR

The plungers of plunger pumps should be constructed of material that will resist the corrosive action of the acid in the water and will not be scored or worn excessively by the packing. The working barrel or liner of piston pumps should be constructed of material that will resist the corrosive action of the acid water and the wear of the packing in the piston.

All the pumps for this class of work now on the market could be much improved. The upkeep on the types of pumps used today is entirely too high, and to that end some radical changes should be made.

In the past year pumps of the self-priming centrifugal type have been constructed and placed in service. These pumps have not been running long enough for their true merits to be determined, but there are indications that under certain conditions they will give better service than either piston or plunger pumps.

It has been recommended that complete detailed specifications be prepared for both piston and plunger pumps. I am much opposed to this as it would be a physical impossibility to write a specification that would not conflict in any way with some of the builders of development pumps. Later on, when we can get a little better co-operation between the manufacturers of this type of pump, would be a better time to give detailed specifications.

RESULTS OF TESTS of a power plant at Rivermines, Mo., using pulverized coal as a fuel, are given in Technical Paper 316, just issued by the U. S. Bureau of Mines. Two boiler tests, six drier tests and eight mill tests were made by the fuel section of the Bureau of Mines, in co-operation with certain engineering firms. The boiler tests were made on two Stirling boilers, each having 7,688 sq.ft. of heating surface, the coal used being weighed as delivered to the preparation plant and before being pulverized. As the coal was passing through this plant, tests also were made of the drying and pulverizing units for the main object of determining the capacity of these units and the power they consumed. During each of the drier and mill tests 100 to 300 tons of coal was dried or pulverized. Bituminous coal from southern Illinois, of good quality for that district, was used. It was shipped as screenings, and the part delivered to the powdered-coal plant contained little slack. The results of the boiler tests are very good when compared with stoker performance under similar conditions.

Peabody Coal Co.'s 1,050-HP. Hoist at Mine No. 9, Calloway, Ill.

Mine-Hoist Control Equipment for Large Installations

Advantages of the Ilgner-Ward-Leonard System—
High Efficiency Hoisting—Automatic Control Features
—Auxiliary Hoisting Motors for Men and Repairs

BY H. W. CHADBOURNE

Power and Mining Engineering Department, General Electric Co.

UNDER certain conditions the Ilgner-Ward-Leonard system of control for large mine hoists has inherent advantages over the induction motor or direct-current motor when operated directly from a constant potential. The principal advantages of this system are that a constant amount of power is taken from the line, and it is possible to get automatic control or a system of control which will respond to many different conditions of load, speed and length of hoist. For short, fast hoisting cycles, this type of equipment also has greater efficiency than can be obtained with other systems of control commonly used on small hoists.

That engineers of both coal and metal mines are realizing more and more the advantages of the Ilgner-Ward-Leonard system is attested by the fact that in eight months the General Electric Co. has received orders for twelve such equipments in sizes varying from 475 hp. to 2,200 hp. capacity. The total horsepower of the hoist motors equals 16,650, all on a 40-deg. C. rise continuous rated basis. Ten equipments were for coal mines and two for metal mines.

Of these twelve equipments, three have drum control and nine have the magnetic type. With magnetic control the strength and direction of the generator field are controlled by a small master switch which carries the contactor control current only, while contactors handle

the field current. This control has been arranged to obtain different results, depending upon requirements. There are a number of advantages of magnetic control over drum type control, either hand or motor operated. First, the master switch is small and the manual effort required from the operator is slight. This is an important item on fast cycles. Second, magnetic control can be arranged very simply to give current limit acceleration if desired—that is, the operator may throw the

FIG. 1—GENERAL VIEW OF SEMI-AUTOMATIC HOIST EQUIPMENT

This hoist is one of the Valier Coal Co., Valier, Ill. On the left is the flywheel motor generator set.

master switch to the full running position and the hoist motor will properly accelerate with the current never exceeding a predetermined value. The current output of the generator is thus kept below an amperage well within its commutating limits.

Ordinarily this control is not connected to give current limit retardation. Should conditions warrant, however, this feature can readily be included. The contactors are so connected that they drop out in sequence, thus giving some time delay. This allows the motor to act as a generator and assist in bringing the load to rest.

UNUSUAL CONTROL FEATURES FOR SPECIAL RESULTS

Unusual features introduced in the control to obtain certain results have been embodied in recent installations, two hoists for the Inspiration Copper Co. being good examples of these innovations. The supply hoist equipment has a motor rated for 600 hp. at 400 r.p.m., with a flywheel set having a 450-kw. generator, a 500-hp. induction motor and a 16,500-lb. flywheel. This equipment has a master switch giving 15

points for automatic acceleration, all of which may be hand controlled. The master switch is located in the hoist house as usual, but the signals for hoisting are given by a man who at times rides the cage and at times signals from the different levels. As a safety precaution an arrangement is made so that it is impossible to signal from any level unless the cage is at that level. This is accomplished by a device similar to a geared limit switch but with eleven contacts, one for each level. The equipment also is provided with an extra control switch for limiting the speed of man hoisting, by preventing the closing of the last field control contactors.

The main ore hoist for the Inspiration Copper Co. consists of a 2,150-hp. hoist motor of 51 r.p.m., a flywheel set consisting of a 1,600-kw. generator, a 1,900-hp. induction motor and a 78,000-lb. flywheel. The main hoist apparatus is located in the same room as the man hoist.

This controller has a motor-operated drum for controlling the generator field, a five-point selective switch mounted near the drum controller in the hoist house and

a system of master switches, one in the hoist house and one at each of the three levels from which ore is to be hoisted. These master switches are in reality small one-point controllers which are under the control of the operator. The direction of hoisting is controlled by two geared limit switches in the hoist house which operate alternately.

The operator sets the selective switch for the correct level and re-clutches the drum, after which the man at the level operates the hoist from that level. It also is possible to operate the main hoist manually from the hoist house.

In order to get variable rates of retardation a cam turn-off device is used which is automatic, the cam turning the drum controller toward the off position at the correct rate to obtain the retardation required. In this case it is necessary to retard at three different rates, besides having a short interval at constant speed. Therefore it becomes advisable to use a cam turn-off device. If an attempt were made to duplicate this condition of retardation with current limit relays it would mean very complicated equipment.

The two equipments also are supplied with a switching arrangement so that the man-hoist motor can be operated from the main generator in case of emergency.

FIG. 2—CONTROL PANEL

Uniformity of arrangement of equipment greatly simplifies the design and maintenance of the hoist control equipment.

FIG. 3—MAGNETIC CONTROL AND SWITCHBOARD PANELS

The switchboard panels are equipped with the usual protective devices. The magnetic control panel shows the control contactors. Illustration shows 1,400-hp. hoist at plant of Homestake Mining Co., Lead, N. D.

One unusual feature of the five equipments ordered by the Old Ben Coal Corporation is that each hoist is equipped with an auxiliary induction motor geared to the opposite end of the drum shaft from the main motor. This auxiliary motor is for use at night and idle periods and operates the drum at a much reduced speed. The hoist builder has interlocked his part of the equipment so that it is not possible to operate the main motor with the induction motor gears in mesh. The control circuits are so interlocked that the auxiliary induction motor cannot be operated when the induction motor of the flywheel set is on the line, or vice versa. Therefore, both equipments—the main hoist motor and the auxiliary hoist motor—cannot be operated at the same time. All of these main motors are also equipped with transfer switches in the control to limit the speed when hoisting men and also to light signal lamps so that the men will know that the control is in the man-hoisting position.

It might be of interest to note some of the work done by such large equipments. The 2,200-hp. motors for the Old Ben Coal Corporation each hoist 8,400 lb. of coal per trip, a distance of about 500 ft. (the distance varies from 484 ft. at one mine to 519 ft. at another), making a trip in 18-seconds, or 200 trips per hour. This gives 840 tons per hour for each hoist, or about 6,000 tons per day of seven hours. The Inspiration Copper Co.'s 2,150-hp. motor hoists 24,000 lb., or 12 tons, of ore per trip. The lift from the bottom level is 1,485 ft. This takes 69.3 seconds per trip, or 625 tons per hour, which is 4,400 tons for a seven-hour day.

Physically the 2,150-hp motor at 53 r.p.m. is the largest hoist motor in the United States. The three

FIG. 4—REAR VIEW OF CONTROL PANEL

The wiring arrangement shows how each part is related to the other. This is the rear of the panel shown in Fig. 2.

2,200-hp. motors for the Old Ben Coal company, being at 110 r.p.m. are smaller mechanically. When ordered, these 2,200-hp. motors were the largest horsepower rated hoist motors in the United States either in metal or coal mines.

DETERMINATION OF FINENESS OF PULVERIZED COAL.—In conjunction with the committee on coal and coke of the American Society for Testing Materials, methods for making size tests of powdered coal, both by hand and machine sieving, have been formulated by W. A. Selvig, assistant analytical chemist, attached to the Pittsburgh experiment station of the U. S. Bureau of Mines, Department of the Interior, and sent to various co-operating laboratories for trial and criticism. This work will be continued with a view to formulating a satisfactory standard for making fineness tests of powdered coal.

FIG. 5—LAYOUT FOR A COAL-MINE HOIST STATION

Here is a large capacity hoist using the Ilgner-Ward-Leonard system of control. The flywheel set is in a separate room, while the power transformers are located outside.

New Equipment

Safety in High-Voltage Line Work

RUBBER blankets have been used for many years to protect linemen from high-voltage current when making repairs. They are awkward to carry and to place. A simple protector for linemen is shown in the illustration. It is in the shape of a hose and has a sort of self-locking arrangement which gives it a firm hold on the wire. Yet it is readily applied and shifted into place

HOSE TO PROTECT LINEMAN
Used in place of a rubber blanket this self-locking hose keeps lineman from being electrocuted.

along the conductor by pressure at one end. It also is quite easily removed. The lineman does not have to lean over far to apply, shift or remove the hose. It is made by W. H. Salisbury & Co., Inc. Of course it always is preferable to deaden the wires by the use of a switch, locked against reclosing, before attempting to do any work on them, but where this cannot be done the hose protection is available and highly effective.

Device for Use on Belt Drives Having Short Pulley Centers

BELT drives always are popular among the mechanical men at the coal mines because of their flexibility and the ease with which the speed of a machine may be varied by changing one or both pulleys without a change in pulley centers.

The photograph shows the Lenix drive, made by F. L. Smidth & Co., of New York, applied to a 200-hp. fan. As will be noted in the picture, the pulley centers are extremely short yet the drive is made highly efficient by reason of the Lenix, which permits of the elimination of 75 per cent of the initial tension found in ordinary belt drives.

A LENIX APPLIED TO A FAN DRIVE

Where the pulley centers are short, the Lenix greatly increases the drive efficiency and at the same time decrease the belt tension.

The best conditions for Lenix drives are with high belt speed and short pulley centers. It also permits high pulley ratios with the use of high-speed motors, resulting in higher efficiencies.

This device is being recommended for mine fans and similar drives, especially where it is either necessary or desirable to have short belt centers.

Saving Mules from Galled Shoulders

ZINC oxide is a well-known antiseptic. On the other hand, leather is a germ breeder. It is surprising therefore that mule collars are still constructed with the rubbing surfaces of leather and not of zinc. Where their collars are made of zinc the shoulders and necks of horses or mules can be kept free from sores. An oxide of zinc forms on the collar and helps the sores to heal, if there are any in process of development. A collar of this kind, manufactured by the Thomson Co., of Fitchburg, Mass., is illustrated herewith. It is easily adjustable and so sweat bands, always unsanitary, which steam the necks, cause sores and are breeding places for germs, are unnecessary. These collars are much lighter than a leather collar for they weigh about 16 lb., whereas the usual collar with hames will weigh as much as 25 lb. Special springs absorb the shock when starting a load or when striking an obstruction. The collars are easy to keep clean as they can be sufficiently cleansed by wiping them with a kerosene cloth. This should be done invariably after using.

COLLAR THAT WILL KEEP THE MULE ON THE JOB

Most of the absenteeism of mules from the mines, apart from that due to lack of coal orders, results from sore shoulders and necks. A zinc collar is said to reduce such absenteeism.

The collars are easy to keep clean as they can be sufficiently cleansed by wiping them with a kerosene cloth. This should be done invariably after using.

This type of horse collar has been in use for more than thirty-five years. During this time it has been gradually improved. Recent changes in design provide for an easy and wide range of adjustments.

A RECENT ADDITION to the list of permissible electric cap lamps approved by the U. S. Bureau of Mines for use in gaseous and dusty coal mines is the Concordia lamp (type RM 6 o.d.), manufactured by the Concordia Electric Co., Pittsburgh, Pa.

How Mines Can Be Moistened Without Use of a Big Force Fan or Obstruction of Haulage Roads

By Using Disk Force Fan in a Subsidiary Intake Conditioned Air Is Delivered to Main Airway, the Ventilation of Which Is by Suction, the Air Being Motionless in Mine Portal

BY THOMAS CHESTER
American Blower Co., Detroit, Mich.

EVERY winter and spring explosions which unmistakably are due to dust occur in coal mines in greater or lesser degree, sometimes causing terrible disaster in which hundreds of men are killed and severe financial loss to the owner.

Normally a tremendous drying out occurs in mines in cold weather and according to a paper read recently to the employees of the Colorado Fuel & Iron Co. by James Dalrymple, chief inspector of coal mines for Colorado, it appears that in that state during the month of March there was an evaporation of 12,991 gallons, or approximately 54 tons, of water per 24 hours for each 100,000 cu.ft. of air circulated per minute. In January and February the evaporation is even greater, but no figures have been published for these months.

Local explosions of gas occur from time to time, but if the general percentage of methane in the mine air is well below the danger point and the coal dust is thoroughly wet, such an explosion will have a limited effect.

Any dry combustible material if in finely divided form can be exploded if suitably distributed in air. Experiments have been made as to the inflammability of about 150 different varieties of dusts produced in industrial work. In this way information has been obtained in regard to the flame temperatures and the pressures generated in pounds per square inch. That the coal is explosive because reduced to dust is shown by the fact that dust explosions occur in factories where fine dusts of combustible material are made as well as in coal mines, and much serious and expensive damage has been done in this way, some examples of wrecked buildings being flour mills, starch factories, chocolate plants, sugar refineries, aluminum factories, etc.

WHY FINENESS CAUSES INFLAMMABILITY

A block of coal will not burn until the surface is raised to the ignition temperature, and the mass retards this rise in temperature by absorbing heat from the surface. Finely powdered dry coal will burn almost in the same manner as a gas and for this reason this material is now used in furnaces as a fuel.

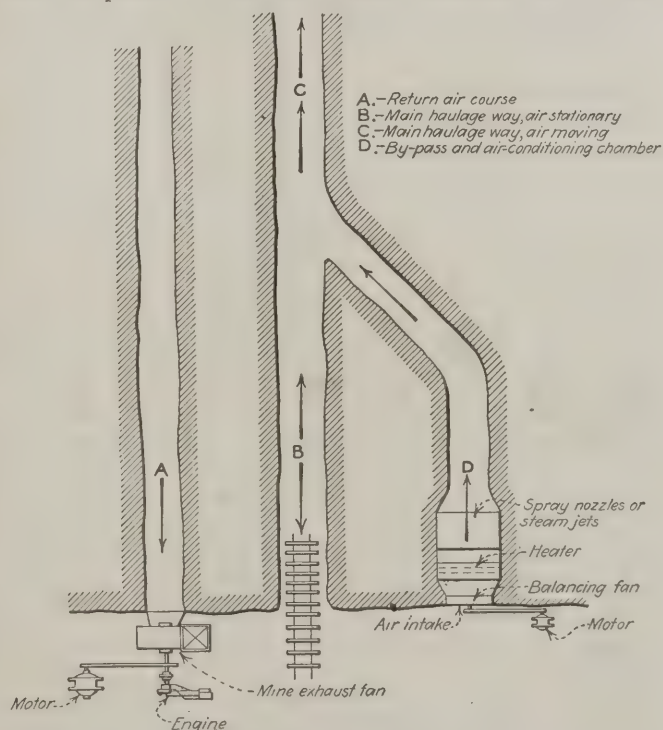

It will readily be seen, therefore, that the sprinkling of water in coal mines is of value because the dust particles thereby are made wet, and this moisture has to be converted into steam before gas can be distilled from the dust particles.

If this absorption of heat is great enough combustion will cease. The same result is achieved by spreading powdered limestone or other finely divided inert material throughout the mine. The substance used in this way absorbs heat and does not subsequently liberate any. Coal dust, on the contrary, absorbs heat at the outset, but upon being raised to the combustion temperature gives off heat in accordance with its calorific value.

It has been established that the more finely divided any combustible is the more rapidly it will burn, whether placed in a pile or distributed in a suitable manner in a current of air. Thus, for the purpose of slowing down the speed of ignition the explosive material used for large naval guns is agglomerated into comparatively large pieces. In this way the explosion is made less rapid. The principle involved is that the more finely divided any material is the much greater is the ratio between the exposed surface and the mass, and conversely the larger the particles the greater the ratio of mass to surface.

Consequently another advantage in wetting coal dust is that it causes the particles to cohere to a certain extent, with the result that the ratio between surface and mass is reduced. Also the increase in weight of the individual particles caused by this agglomeration and by the saturation with water reduces the ease with which dust can be blown into the air from the floor of an entry.

Serious mine explosions seldom occur in summer. This is because a comparatively large quantity of water vapor is present in the outside atmosphere. In passing through a mine this air is cooled below dewpoint, with the result that water is precipitated in the form of dew. After a period of hot and humid weather it is often

CONDITIONS AIR AND PASSES IT TO MAIN ENTRY

By means of a fan air is driven into the main entry beyond the portal at such speed as to satisfy the exhaust fan. Consequently the air between the portal and the point of entry of the conditioned air is stationary.

found that mines are wet to the face of the longest entry on account of this condensation.

The quantity of water vapor in a cubic foot of saturated space of air at various temperatures with normal barometric pressure is as indicated in Table I.

TABLE I—GRAINS OF WATER VAPOR IN CUBIC FOOT OF SATURATED AIR

Deg.	Grains	Deg.	Grains	Deg.	Grains
10	0.776	34	2.279	58	5.370
12	0.856	36	2.457	60	5.745
14	0.941	38	2.646	62	6.142
16	1.032	40	2.849	64	6.563
18	1.128	42	3.064	66	7.009
20	1.235	44	3.294	68	7.480
22	1.355	46	3.539	70	7.980
24	1.483	48	3.800	72	8.508
26	1.623	50	4.076	74	9.066
28	1.773	52	4.372	76	9.655
30	1.946	54	4.685	78	10.277
32	2.113	56	5.016	80	10.934

Air having a dry-bulb temperature of 95 deg. and a wet-bulb temperature of 77 deg. carries about 8 grains of moisture per cubic foot and has a relative humidity of about 47 per cent, which means that it is 47 per cent saturated.

If this air is cooled down to 70 deg. it will still carry about 8 grains of moisture per cubic foot, but then will be in an almost saturated condition or nearly at dew-point. If this air is cooled down to 60 deg. it will still be saturated, but will then carry 5.745 grains of moisture per cubic foot, as will be noted from the above table, and the quantity of water condensed out of the air will be 2.235 grains per cubic foot, and it is the deposition of this moisture which makes a mine wet in summer.

This action can be produced artificially in winter by heating the air to the required temperature and loading it with moisture before it goes into a mine. Usually it is not necessary, however, to actually deposit moisture in a mine during winter, as in most cases this action is produced naturally during summer and autumn; all that is necessary in winter is to prevent evaporation. This is done by raising the air temperature to permit of the absorption of water, and the moisture content is brought up as near as required to saturation at the mean temperature of the mine—that is to say, of the coal seam and roof.

Dust explosions can be produced by runaway cars, collisions, rock falls, blown-out shots and by local gas explosions. Any one of these can stir up enough dust to start a general explosion, which is intensified as it passes through the mine. After a dust explosion is well under way the velocity of the detonating wave reaches about 2,000 ft. per second with great heat and pressure.

If exhaust steam is blown into the air entering a mine, much water is precipitated and fog is produced owing to the fact that the cold air cannot take up the moisture in the form of invisible water vapor, but this is possible when the air is preheated.

Moisture can be added to mine air by providing water sprays at intervals which permit suitable increments in the quantity of water vapor carried as the air temperature is gradually raised by contact with the airway surface. The logical plan, however, is to concentrate the air-moistening equipment on the surface, where it can be given attention, and where any necessary variations in temperature and relative humidity easily can be produced.

When a mine is ventilated by a fan operating as a blower it is easily possible to place the air-conditioning apparatus between the fan and the intake drift or down-cast shaft. When a mine is ventilated on the exhaust principle the condition is not quite so simple, as it is not desirable to use double doors or air locks to enable the

intake air to be suitably conditioned, because this would interfere with taking out coal as rapidly as possible.

Martin J. Lide, consulting engineer of Birmingham, Ala., has developed and patented a system whereby this difficulty can be overcome satisfactorily. The Lide system consists of the use of a disk fan for blowing all the air which goes into a mine, through a bypass which enters the main haulage slope or shaft some distance within the portal or collar, as the case may be. A suitable area of heating surface is furnished for raising the air to the required temperature and either water-spray nozzles or steam jets are used to add moisture.

By using the bypass and disk fan the mouth of the slope or shaft is kept in a neutral condition as regards air movement and there is no interference with the haulage of coal. The inflowing air passes through the disk fan and air-conditioning apparatus and through the bypass to the mine. This will be clear from an inspection of the sketch herewith, which gives a plan of an installation of this character applied to a drift mine.

With the Lide system the air can be supersaturated when required, so that during shutdowns moisture can be deposited in the form of dew by the air used for ventilation. This is much better than sprinkling, because men who have to work in dark places cannot be sure that their work is well done. Moreover they are not always actuated by a desire to perform their work thoroughly.

This system can be best applied to mines which are equipped with power plants and have a large quantity of exhaust steam available, but operations which use purchased power can use low-pressure steam from a plant installed for this purpose. This need not be expensive, as second-hand boilers can be used for the low-pressure needed and waste coal can be burned by installing a forced-draft fan.

If evaporation is prevented in cold weather, as indicated, and if the rooms are sprinkled wherever coal-cutting machines are at work, it will be found possible greatly to reduce or wholly to eliminate dust explosions.

French Coal Imports and Exports in July

French imports and exports of coal and coke in July of this year and for the first seven months of the year were as follows, in metric tons:

Coal	Imports		Exports

Group Insurance as an Aid to Reducing Mine Accidents

Safety Engineering Department of Large Insurance Company Makes Recommendations—Analysis Covering Fifteen Months Indicates Possible Reduction of 75 per Cent—Employee Safety Organization Highly Effective

BY THOMAS A. WALSH
Safety Engineer

SERVICE is more than delivering satisfactorily that which has been sold. It is more than commercial cleverness. Service is the secret of success. President Coolidge has said: "The business of the country depends upon private initiative. It depends upon good-will and a desire to serve more than ruinous competition and a desire for gain."

In a recent article in *Coal Age** the possibilities of a better understanding between employer and employee through group insurance was pointed out. Attention was drawn to the number of coal companies that had adopted group insurance as a means of establishing better relations between themselves and their workers. It is recognized that a sincere and an active interest in the physical safety of the men on the part of the employer is another approach toward cementing the tie between them.

Realizing this fact, one of the large insurance companies has established a service bureau which, among other services, has a safety engineering department. As one of the safety engineers of this bureau, I recently visited a group of mines that had purchased group insurance and were anxious to have me make a survey and supply them with recommendations for reducing accidents among their workmen. After spending several weeks making careful investigations of this company's operations, covering eight camps and fifteen mines, a report on the conditions found, which included recommendations for accident prevention, was prepared. This article is based on that report.

Analysis Reveals Heavy Loss in Output and Expense.

—Preliminary to the survey, an analysis was made of 575 accidents involving a loss of time of one day or more, in all the mines for a period of fifteen months. This analysis showed that because of accidents and on the basis of weighting as established by the International Board of Accident Commissions, there were 110,000 days lost in this fifteen months' period, with a coal production loss of 495,000 tons and an accident cost of approximately \$50,000, totaling an operating loss of approximately \$1,040,000.

As indicated by Fig. 1, 40 per cent of these accidents involved miners and 35 per cent transportation men as follows: brakemen, 20 per cent; trackmen, 10 per cent, and motormen, 5 per cent. Miners and transportation men sustained 75 per cent of all accidents for the period. These accidents were responsible for 86 per cent of the total tonnage loss due to accidents, as shown in Fig. 2. The remaining 25 per cent of the total accidents reviewed affected machine men, timbermen and others in varying percentages from 5 to 1. Fig. 3 indicates that 36 per cent of all accidents are attributed directly to slate and coal falls; 15 per cent occurred

in transporting material and equipment and 11 per cent in handling material in the course of producing coal. The remaining cause classifications in Fig. 3 are of varying importance, with a maximum of 17 per cent for all other causes to 1 per cent for nail punctures and explosions.

A study of this cause chart indicates that a possible reduction of 75 per cent of all causes can be looked for, with an immediate reduction of 50 per cent in the classification of slate and coal falls alone. There also are presented diagrams of accident severity and frequency rates, computed on a monthly basis and comparing the ratio of accidents and days lost due to these accidents per 100 men for eight camps. The annual average monthly accident rate is 1.2 per 100 employees for all mines, and the severity rate is thirty days per 100 men employed. The fatality rate is 3.5 per 1,000 employees.

Causes of Accidents.—The company is doing everything practicable to eliminate accidents from a physical point of view. Physical conditions of the properties, both on the surface and underground, are good. These conditions are maintained through the efforts of a competent mine inspector. His work is largely that of inspecting the various mines from the point of physical safety. He has the fullest co-operation of all officials, from the general manager down to assistant mine foremen. But physical conditions involve probably only 10 per cent of those factors which when corrected tend toward accident elimination.

A study of the diagrams indicates that accidents

FIG. 1—DISTRIBUTION OF ACCIDENTS BY OCCUPATIONS

This diagram shows that more miners meet with accidents than men in any other work around the coal mines. It appears, however, that the accident rate is higher among brakemen since there are many miners to each brakeman employed.

*"Group Insurance: What It Is and Its Advantages to Employer and Employee," by R. W. Sparks; Aug. 16, 1923.

FIG. 2--ACCIDENTS AS A CAUSE OF LOST PRODUCTION

According to the analysis of accidents at these fifteen mines, accidents to miners cause the largest loss in production, with brakemen second. That accidents to brakemen figure so largely is evidence of the importance of transportation in getting coal to the tippie.

involving the negligence of the personnel compose a greater proportion of the total than those attributed to defective structural conditions of the property, either on the surface or underground. To effectively reduce this present high accident rate, which is largely due to individual carelessness, it was suggested that a safety organization be developed, including formation of safety committees, holding of meetings, carrying on of efficient educational work in accident prevention through the use of bulletin boards, pay envelopes, etc., and the investigation of all accidents involving loss of time.

The plan proposed should easily be launched and maintained, due to the exceedingly good feeling existing between employees and this employer and because of the favorable attitude of the general manager and the mine officials generally. Under such favorable circumstances, measurable results from the efficient operation of the plan should be quickly realized.

Where accident-prevention work is made part of the operating practice of the industry and is administered through efficient methods, effective results as indicated are obtained. As an indication of what can be done the following notes from records available to the writer are suggested. The A Coal Co. recently, during a period of approximately one year, has reduced the number of lost time accidents 51 per cent and in the same period reduced the number of days lost due to such accidents 85 per cent. The hours worked increased 2 per cent. The tonnage mined per day increased 11.2 per cent. There was a 68 per cent reduction in accident cost per ton of coal mines accompanied by a 72 per cent decrease in accident cost per \$100 of payroll.

The B Coal Corporation passed through 1919 without a single fatal accident and with a reduction of more than 70 per cent in non-fatal accidents for the same period. Compared with a previous year's record of 2,212 non-fatal accidents, the record for 1919 was 1,717 non-fatal accidents.

The C Coal Co. reports that it has reduced its fatality frequency rate from 1 for every 84,972 eight-hour shifts worked during the period from 1913 to 1916 to

an average of 1 for every 400,727 eight-hour shifts worked during the years from 1917 to 1920. From Jan. 15, 1918, to Aug. 2, 1920, this company operated 763,000 eight-hour shifts without a single fatality.

The D Coke Co. reports that it reduced its rate during 1920 to 1.71 deaths per million tons produced. The E Coal Co., of West Virginia, reduced its accidents 18 per cent in 1920 from 1919. It has reduced fatalities 33 per cent, while at the same time increasing output.

The F Steel Corporation since 1906 has reduced serious and fatal accidents 56.13 per cent and further reports that since 1912 accidents causing a loss of time greater than the working day have been reduced 71.41 per cent.

In all of the foregoing instances the personal factor of the operation has been considered as the governing one in the reduction of accidents. Accidents can be reduced only through the combined efforts of all concerned. For this particular company the following program of accident-prevention work in its various camps was designed and recommended:

Plan for Safety Organization.—Central safety, mine safety and, where feasible, sectional committees should be organized.

The Central Safety Committee should be made up of the general manager as chairman, safety engineer, general superintendent, chief engineer, maintenance engineer, claim man, and superintendents of the various mines.

The Mine Safety Committee should consist of the mine superintendent as chairman, the safety engineer as secretary, the mine foreman, assistant mine foreman, mine electrician and workmen. The assistant mine foreman and the workmen to be rotated.

The following schedule of items is suggested for the consideration of the committees at their meetings:

Central Safety Committee

- (1) Review abstract of minutes of mine-safety committees.
- (2) Review all mine accidents occurring during previous month.
- (3) Receive recommendations for the prevention of such accidents.
- (4) Receive review of recommendations submitted by the mine committees to this body with the idea of making them standard practices, wherever possible.
- (5) Consider accidents on a basis of loss in production and insurance cost.
- (6) Assist in the development of general operating rules.
- (7) Every two months appoint a special committee to make a survey of at least one mine with the idea of promoting better safety conditions in the particular mine visited. A detailed report of this inspection should be submitted, with recommendations, to the Central Safety Committee.
- (8) Keep in touch, as far as practicable, with all new safety devices or methods developed for the prevention of accidents in their particular industry.

Mine Safety Committees

- (1) Report and review all accidents occurring in the particular mine.
- (2) Consider suggestions and recommendations submitted by members and others regarding accident-prevention methods, sanitation and welfare.
- (3) Submit for approval to the Central Safety Committee such recommendations as should become part of the company's standard practice.
- (4) Initiate and arrange for the carrying on of educational work in accident prevention among employees of the mine concerned.

The Court of Inquiry should be a special committee,

appointed as accidents occur, by the chairman of the Mine Safety Committee to investigate the serious accidents and fatalities. The organization of the Court of Inquiry would comprise the mine superintendent as chairman, the camp doctor, the safety engineer, the foreman in charge of the employee who was injured or killed, and witnesses to the accident. The duties of this Court of Inquiry would be to determine the cause and the responsibility for the accident. A questionnaire compiled along the following lines may serve as a guide to this committee:

- (1) Date of the accident.
- (2) Doctor's statement as to physical condition of injured when visited by him.
- (3) Foreman's and assistant foreman's report of the accident.
- (4) Witnesses' reports of the accident, supplemented by photographs, drawings or other data relating to the physical conditions of the plant or machine where the accident occurred.
- (5) Consideration by chairman, mine superintendent and safety engineer of data presented by those interviewed and findings by the members of the committee as to
 - (a) Cause of the accident.
 - (b) Responsibility for the accident.
 - (c) Recommendations to prevent a recurrence.
- (6) These findings should be submitted in a report to the president and other executive members of the company through the chairman of the Central Safety Committee.

Duties of Mine Safety Engineer.—To head up this plan and to be responsible for the detailed operation of it, it is suggested that a mine safety engineer be charged with the duties as listed below:

- (1) Have general supervision of all safety work.
- (2) Make regular safety inspections of all mines accompanied by a mine official.
- (3) Where necessary, expedite all safety recommendations.
- (4) Analyze all accident reports and investigate all accidents for the purpose of taking steps to prevent their recurrence.
- (5) Inspect all mine-rescue apparatus for the purpose of seeing that it is in readiness for any emergency.
- (6) See that all first-aid stations are properly maintained.
- (7) Check all drawings and co-operate with the operating and construction departments that safety standards in physical conditions of the mines are maintained.
- (8) See that proper safety specifications are provided for new equipment.
- (9) Follow up machinery contracted for from outside shops to see that standard guards are provided where required.
- (10) Supervise and conduct all safety educational work.
- (11) The development of safety bulletins should be under his supervision as well as the provision of standard danger signs to be used where necessary throughout the mines.
- (12) Attend all safety committee meetings and act in an advisory capacity and, as secretary to each committee, prepare all reports.
- (13) Under the direction of the mine superintendent institute all hearings of courts of inquiry and prepare reports of same.
- (14) Supervise all training of first-aid and mine-rescue teams.

FIG. 3—CLASSIFICATION OF ACCIDENTS BY CAUSES
The more important causes of accidents will be recognized as those peculiar to the mines.

- (15) Supervise the general sanitary conditions of all mine camps.
- (16) Supervise the organization and maintenance of all fire-protection methods and equipment applied to the mines and camps.
- (17) Submit to the management a monthly report of the activities of his department involving
 - (a) Number of lost-time accidents—time lost.
 - (b) Number of non-lost-time accidents.
 - (c) Total number of accidents.
 - (d) Causes of lost-time accidents.
 - (e) Costs involved through lost-time accidents, non-lost-time accidents, and departments or mine sections involved.
- (18) Be responsible where the occasion requires for handling all details relative to workmen's compensation.

Safety Education.—In conjunction with committee organization, one of the most important requirements for efficient accident prevention work is education through the following or similar methods: (a) Bulletin boards, (b) payroll inserts, (c) home-made bulletins describing mine accidents with suggestions of prevention, (d) publication monthly of the comparative accident standing of the company mines in general and sections of the individual mines with the names of the foremen in charge of such sections. These ratings should be posted on the bulletin boards as well.

It has been observed that although many coal companies have gone to considerable expense in providing bulletin boards they do not always appear to realize what they should on their investment because the boards are not properly maintained. Bulletins are always a source of interest to employees and form one of the most important links in the chain of safety education.

It is suggested that a safety bulletin board service be developed in the following detail:

- (1) Accident-prevention bulletins should be placed on a well-constructed board devoted entirely to this use.
- (2) These boards should be located at points where employees congregate in leisure hours. Such places may be check boards, near entries to mines, outside of time offices, at first-aid stations or other gathering places.

(3) Bulletins should be changed frequently; preferably each week and on a scheduled day.

(4) The type of bulletin posted should be varied by using (a) those of the National Safety Council; (b) cuts from publications relative to hazards of the coal-mining industry or sections of it; (c) home-made posters exhibiting defective material or tools that may cause or have caused accidents. Such bulletin should be placed as near as possible to the section of the mine in which the accident occurred or in which the hazard illustrated is most closely related to the work of the employees. This method will make the most direct appeal.

(5) One bulletin at a time should be used. Four or five posters on the board at one time scatter attention and lessen the educational effect of the point dealt with.

(6) At regular intervals there should be placed on the board graphic presentations of department or sectional standing, also the standing of the various mines in relation to one another. This can be done by showing the number of lost-time accidents in a department or section and the days lost through such accidents. By applying this method to the several mines, accidents and days lost may be totaled for the mines as a whole, so that the accidents and days lost for each mine may then be compared.

(7) It has been found effective to mail to the homes of employees bulletins having an appeal to employees' dependents. This is done in order to obtain the co-operation of families in the work of reducing accidents.

(8) Instead of destroying old and discarded bulletins, they should be given to the local school teachers, police or fire departments.

Probably one of the most effective means of education in accident-prevention work is to bring to the attention of employees at frequent intervals information regarding the subject through the use of payroll inserts. If possible these inserts should be developed from actual company accident experience.

In this case it was suggested that the fifteen mines of the company be put on a monthly competitive basis, through the listing of the number of lost-time accidents occurring, naming the foreman in charge of the particular section in which the accident occurred, and by showing the estimated days lost due to accidents under the various foremen listed.

In connection with placing sections of individual mines on a competitive basis it has also been found practical to have camps compared as units, thus creating a friendly rivalry between the various mines of the company. Successful results frequently are obtained along the line of comparative safety standings through the use of targets, thermometers and other methods of portraying graphically to the employees the number of lost-time accidents occurring in each mine with the total

days lost due to these accidents and the consequent effect on coal production.

New Employees.—Casualty statistics indicate that a large percentage of accidents happen to new employees. The company has taken definite steps to control these hazards by issuing rule books to new employees. Rule books should be developed having more specific facts bearing on the causes of accidents. Such information can be easily obtained through an analysis of the present accident statistics and thereafter rules developed which will concretely apply to specific classes of hazards. The development of such a rule book might be made a part of a program of the safety committees. When undertaken by such committees the preparation of rules invariably has the effect of acquainting the employees with the serious hazards of their work and methods of offsetting them. When the rules are developed by the employees themselves they are likely to be adhered to more closely.

It should be a part of the duties of safety committeemen in the various mines to instruct new men in the elements of the safety rules. Such a practice increases the interest of the old employees and puts the new man on a footing of greater confidence with the men with whom he is about to associate daily on the job.

In order that the personnel of the safety committee may attain standing in the mine or community it has been found practical to designate the members of the safety committee through the use of safety buttons or badges. The safety buttons or badges usually are given to a man at the time of his election to the mine safety committee, and he retains it as a token of appreciation by the company for his interest in accident-prevention work.

Many companies have found it helpful to hold at least once a year a large mass meeting of all employees and their families, with the primary purpose of promoting accident prevention. Sometimes these meetings are conducted in the summer in the form of outings; at other times they are held in the winter in theaters or large halls. This method probably is one of the best means of enlisting the aid of employees' families in safety practice. When rallies are held in the hall, one or two reels of motion pictures on causes of accidents have been found effective.

To launch the proposed program of safety organization in this company's camps it was suggested that a general meeting be held in each of the camps, at which time the employees may be addressed on the importance of the work to be undertaken, what lost-time accidents have meant to them through diminished wages, and how their personal efforts are the largest factors in controlling the accident situation. Such talks could be supplemented with motion pictures on mine accidents.

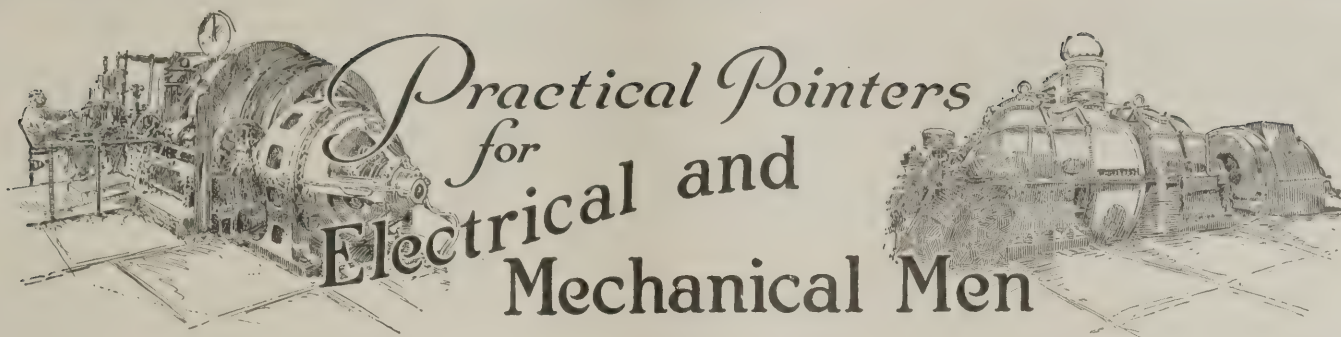

FIG. 4—RECOMMENDED ORGANIZATION FOR PROMOTING SAFETY

The most important feature of this plan is the subcommittee, through which the co-operation of the men can be gained.

Drilling of Brass Made Easy By Properly Shaping the Drill

INDUSTRIAL brass is divided into two classes, cast brass and wrought brass. Cast brass varies in its zinc content from 30 to 40 per cent. The popular proportion is 35 per cent zinc and 65 per cent copper. If a small percentage of tin is in the mixture the drilling will be considerably easier. Often brass will be found to be exceedingly soft and ductile dragging severely under the cutting action of the tool. When drilling this kind of brass the work can be made somewhat easier by seeing to it that the drill is ground properly and that a lubricant is used which will really assist the drill in cutting and not cause digging into the work.

The one most important thing is the resharpening of the cutting edge of the drill which has been ground to the usual commercial shape. The cutting edge on the lip of the drill should be ground in a way that will eliminate the angle of keenness. It is this wedge-shaped lip of the drill that causes it to dig into the brass especially on sheet brass and brass low in tin content. The accompanying sketches give a better idea of the drill lip before and after grinding. The grinding of the drill lip to this shape can be facilitated by grinding on the side of the wheel and not on its face. Drills ground for

drilling brass must be reground to their normal cutting edge when again used for steel and cast-iron drilling.

Brass usually is drilled dry, but lard oil is used on very high speed work. On a job where the drill is digging into the work, however, a few drops of kerosene or cutting compound may be used as a lubricant. A good, cheap cutting compound that will be found useful around a shop is made as follows: 1 lb. sal-soda (carbonate of soda), 1 qt. lard oil, 1 qt. soft soap and enough water to make 10 gallons. Boil this mixture one half hour. This solution may be stored, in the same manner as oil and used for cutting-tool lubricant at a considerable saving in cost.

Urbana, Ill.

Use of Borehole Cables for Efficient Power Distribution

ONE of the important advantages resulting from the use of central-station purchased power at coal-mine operations is the use of alternating current and the relative ease with which it is possible to deliver electrical energy at that voltage which is most effective for each piece of equipment. Substations can be located at points most convenient to the center of the load so as to deliver power with the minimum voltage drop and best regulation.

The general tendency is to have the power company deliver energy at a point on the property where its distribution may be made to the equipment through short distributing lines and cables. The best modern practice for the delivery of electrical energy to substations located inside the mines is by means of insulated cables placed in boreholes. This system of distribution may be employed to advantage whether the mine be of the shaft, slope or drift type, except in special instances where the topography of the surface makes such an arrangement impracticable.

For economical reasons the mine substation usually should be located underground and supplied by high voltage current. This is true whether the substation be a converting station for changing alternating current to direct current or whether the substation be a transformer substation feeding alternating current to hoist, pump, compressor or similar drives.

With the more extended use and development of the full automatic converting substation, this practice may be changed or modified. In any event, boreholes for carrying cables of either high- or low-voltage ratings to the inside mine-distributing center will continue to be a necessity if the economies of operation demanded by modern operating conditions are to be realized.

There are still many operations at which the generating or transforming equipment is located in a sta-

CUTTING EDGES FOR STEEL AND BRASS

In turning, planing or drilling steel the cutting edge is shaped to cut into the metal, while for brass the cutting edge is made perpendicular to the brass surface so as to have a scraping action. It is important on drills to have the plane of the cutting edge parallel to the axis of the drill.

tion at or near the mine opening. It is advisable and may later become necessary, however, to locate an inside substation and deliver the electric power at the working face with a minimum voltage drop. In such cases an underground substation or inside electric power distributing center will be advisable and the surface connection will be by means of insulated cables installed in boreholes properly cased and sealed.

When such equipment is installed it is most important that provision be made for the proper placing and protection of the casing in the borehole, the cable suspension and the cable insulation.

Present practice is to drill the borehole from 2 to 3 in. larger than the outside diameter of the casing or conduit to be used, and fill the space between the casing and borehole sides with cement in order to protect the casing properly and also prevent water seepage. Where ordinary pipe casing is used it should be thoroughly cleaned on the inside and given a protective coat of some compound that will prevent corrosion. Plain black iron conduit can be bought in sizes up to 5 in. and, inasmuch as such pipe is made smooth on the inside and has a protective coating, its use is desirable in all cases where an inside diameter not exceeding 5 in. meets the requirements.

It is imperative that the top of the borehole be thoroughly sealed and protected so as not to admit air or water. The casing has a natural tendency to condense moisture when air circulates in it. With the top sealed, however, there is practically no air movement and the heat generated in the cables readily dissipates any slight moisture that may be present.

When the transformation from alternating current to direct current is made on the surface, larger and heavier cables are necessary than in cases where this transformation takes place underground. This is true because of the much greater currents, at the low-voltage direct-current, which must be transmitted through the borehole cables to the mine workings.

Though insulating problems increase as the voltage is raised, present knowledge of insulating materials makes possible a thoroughly reliable and practicable cable for use at any voltage that is likely to be employed. These cables are not only electrically safe but also are mechanically strong enough to withstand the stresses and strains they must bear.

The usual direct-current voltage employed is 250/275. Occasionally 600 volts direct current is used. The alternating-current voltage most frequently used is 2,200. There are few cases where a voltage in excess of 6,600 will be required.

For 2,200-volt service or higher, lead-covered iron-armored triple-conductor cable with steel supporting wires is highly satisfactory. In fact, in certain cases the use of this type of cable is imperative. In many cases, however, single conductor cables with weather-proof insulation but without lead covering or armor, are preferable.

It is essential that all steel armor or supporting wires be thoroughly protected from the action of moisture and mine air, in order that corrosion may be prevented. Such a cable often is difficult to handle because of its weight, and it also has the added disadvantage of being extremely difficult to repair in case of failure. With iron-armored cable a special supporting device is used, so located as to place the weight of the cables directly on the borehole casing.

When single conductor cables without lead covering

BOREHOLE CABLE SUPPORT

These supports can be made very efficient and yet reasonable in cost by the use of standard line equipment and material commonly used about a coal mine. The borehole casing should be effectively sealed to prevent corrosion by moisture condensation inside the pipe.

or armor are used, the entire weight of the cables is carried by the copper conductor and supported on a frame built directly over the bore hole. Local conditions will usually determine the character of this support, but in any event, it will be relatively inexpensive. By reference to tables showing the weights that copper conductors of various size will support, the maximum permissible length of cable for a given size can be determined without difficulty.

The ease with which borehole cables can be removed for inspection and repair, of course, is dependent on whether armored or unarmored cables are employed. In the former case, removal is necessarily very difficult because of the weight and relative inflexibility of the cable, whereas the unarmored single conductor cables can readily be brought up for inspection and repair by the men employed at the mine. With ordinary care in the installation and maintenance of borehole cables, defects are not very likely to develop.

BOREHOLES WARD OFF ABRASION, MOISTURE AND AIR

In cases where it is desired to carry a mine telephone circuit down the borehole alongside the power cables, it is essential that the telephone circuit be enclosed in a thoroughly grounded metallic covering. Often it may be deemed advisable to carry the power cables down a borehole made expressly for the purpose, even though the hoisting or ventilating shafts may be conveniently available. The borehole affords the cables protection from abrasion, moisture and air, as well as from other disturbances encountered in open shafts, which in almost every instance more than justifies the additional expenditure required for cable boreholes.

The advantage of mine substations connected to the outside by cables installed in boreholes will be increasingly evident. The substation can be readily located at accessible and convenient, yet out of the way, points, and can be moved as required and make possible most efficient application of electric power to the mine workings.

Use of Steel Track Ties in Heavy Motor Haulage

Efficiency in Heavy Traffic Doubted—Instance of Wooden Ties Replaced by Steel Ones—Useful in Rooms, Pillarwork and Back Entries

THE reply given to the inquiry regarding the use of steel track ties, in mines where heavy motor haulage is employed, expresses the opinion that there are limitations to the use of steel ties in mine tracks and asks for the experience of others in this regard. My own conclusion accords with that expressed by the editor, namely, that steel track ties are not as efficient where 10- and 12-ton locomotives are in use.

Experience with the Fairmont, Cambria and Carnegie steel mine ties leads me to say that, while the ties are useful and efficient wherever it is practicable to use them, I do not consider that main haulage roads in mines is their province. When taking charge of the Raleigh Wyoming Coal Company's mines, at Edwight, W. Va., as superintendent, I found all the mine roads laid with steel ties.

DIFFICULTY EXPERIENCED WITH STEEL TIES

There was so much difficulty in keeping the tracks in alignment on the main road, that I found it necessary to replace the steel ties with wooden ones, in order to secure a more stable track. The wooden ties enabled the track to be properly aligned, ballasted and surfaced, which I had found practically impossible to accomplish with the steel ties.

Let me say, however, I consider it good practice to use steel ties, in combination with the wooden ones, on main haulage roads, spacing the steel ties about 10 ft. apart. The use of the steel ties, at intervals of 10 ft., prevented the spreading of the track, in case a section of wooden ties failed because of dry rot.

It will often happen that wooden ties will get in this condition and give way before they are discovered, even in the best managed mines. Where dry rot has set in, the weakened condition of the tie does not appear on a casual inspection of the track; but a derailed car will quickly find the weak part and the result is a wreck of the entire trip, before it can be brought to a standstill. A few steel ties spaced between the wooden ones will generally prevent this accident and avoid delay in haulage on the main roads.

It is my belief that the province of steel mine ties is largely in rooms, pillarwork and back entries or air-courses that are cut off every 200 or 300 ft., making it necessary to pick up the track in sections and move it forward. Steel ties can be used with great success for extension or jumper rails, until the face of a working place is advanced far enough to permit the laying of a

full length of rail and permanent track. Also, steel ties may be used to great advantage on all temporary tracks, in haulage roads.

Charleston, W. Va.

J. W. POWELL.

ANOTHER LETTER

Steel ties give satisfaction under 15- and 20-ton locomotives—In use for 10 years in another mine putting out over 5,000 tons of coal per day, with 8-ton locomotives.

REGARDING the use of steel track ties, in heavy motor haulage in mines, permit me to say that we have been using these ties in the mines of the Old Ben Coal Corporation for many years and they have given good satisfaction. In our Mine No. 16 we are using ties under 15- and 20-ton locomotives.

Our oldest installation of this kind is at Mine No. 9, West Frankfort, Ill. We started this mine, in 1913, with a complete bottom layout of steel ties on our main haulageways. When the installation was first completed, we were using 6-ton locomotives; but, during the past six years, we have employed 8-ton locomotives entirely, in that mine.

The fact that during this period, Mine No. 9 has produced from 5,000 to 5,500 tons, each day that the place has worked, gives a fairly good idea of the traffic conditions. I am advised by Superintendent Dunn, in charge, that it has never been necessary to replace a steel tie, in the bottom layout just mentioned.

While there are, no doubt, many mines where the local conditions are such as to render the use of steel ties unsuitable, that is not the case in our field, where we have found their use very much worth while. The question of whether steel ties will stand up under heavy locomotives is best answered by saying, Select a tie that is heavy enough to take care of the duty required.

P. W. BEDA, Vice-President,
Old Ben Coal Corporation.

Chicago, Ill.

Keeping Water Out of Slope

Shallow mines liable to be flooded in wet seasons—Concrete lining must include inverted arch at the floor.

THE difficulty encountered by Joseph Magdalena, regarding the flooding of his slope mine during a rainy season, as described in his letter, *Coal Age*, Aug. 23, p. 291, is no doubt typical of most shallow mines. He explains that, after going to the trouble and expense of lining the top and ribs with solid walls of concrete 18 in. in thickness, the water still came in through the floor of the slope.

His proposal to place a door at the inby end of this concrete lining, at the foot of the slope, has the objection that it would not be possible to work the mine during a flood. The loss on this account, together with the addi-

tional cost of pumping the water from the 300-ft. slope, he would find a large item—too large indeed to be considered from an economical standpoint, in the operation of a mine.

Allow me to suggest lining the floor of the present tunnel with a concrete lining, in the form of an inverted arch, as shown in the accompanying figure. If this work

LONGITUDINAL AND CROSS-SECTION OF SLOPE

is done in sections and care taken to give the concrete floor a good bedding and to secure a watertight joint with the lining of the ribs, I believe the plan will wholly eliminate the trouble, by preventing the seepage of water with which he is now contending.

To insure a complete job, let me say the concrete lining, including the roof, sides and floor, should be extended a distance down the slope to where the coal is found to be solid and free from breaks. At that point, the lining should be extended in wings to give it a better connection with the strata, as I have indicated in the longitudinal section shown in the figure. The depth of these wings will naturally depend on the nature of the strata. Finally, should the lining at any time show signs of leakage, a cement-gun should be used to make it watertight.

CYMRÖ.

Superior, Colo.

ANOTHER LETTER

Work of lining the slope incomplete—Flooding of the mine only what might naturally be expected—Lining should have been in the form of a barrel.

AFTER carefully reading the letter of Joseph Magdalena, *Coal Age*, Aug. 23, p. 291, asking for suggestions regarding the best means of preventing the flooding of his slope mine, which has occurred always at the time of the spring rains, my conclusion is that the work done in lining the slope was incomplete.

The inquirer says that the slope was started in a bed of quicksand 30 ft. deep and driven on an inclination of 11½ deg. Because the mine was twice drowned out, by water running down the slope, that opening has been lined with 18-in. concrete walls and roof, extending down both sides of the road a distance of 300 ft. to the coal, at a cost of \$9,000.

The statement that, in spite of all this, water continued to seep down behind the walls and came up through the floor, shows that the result was only what one would naturally expect. To my mind, the work was only three-fourths complete, as the floor of the slope was still left exposed and unprotected.

My plan would be to line this slope with an extra good brick wall, in the form of a barrel, and further protecting this with an inner lining of concrete. At the entrance or portal I would build a wall about 4 ft. high to prevent any water running into the slope at the mouth. This double wall of brick and concrete should be extended to the coal, which should be sheared to present a

good solid face. Beyond this point, the concrete lining should be extended say 20 ft. along the coal ribs.

Such a plan I feel sure would have put an end to any further trouble from water entering the mine through the slope. As the work progressed, the track should be laid on a good bedding of waste material held in place by crossboards. This ought to provide the needed protection and prevent any damage being done to the slope lining should cars be derailed.

With regard to the steel door, which the inquirer proposed to build at the foot of the slope, I fail to see the need of such a trap. In my opinion, it would be both useless and dangerous. Allowing the mine has another opening that would permit of the place being worked at the time of a flood, neither could the door be made watertight or capable of withstanding the great pressure, estimated as 112 tons when the slope is full of water.

Before closing, let me say that if the mine openings extend under a creek bottom, there should be heavier walls of brick and concrete, at that point, to guard against a possible break in the strata and the flooding of the mine by a sudden inrush of water from the creek.

OSCAR H. JONES,

Wilder, Tenn.

District Mine Inspector.

Finding the Remedy

Ineffectual efforts to prevent the occurrence of explosions in mines—Regarding the situation broadly—Ventilation the greatest need.

MANY have been the causes assigned by different writers, in *Coal Age*, as being responsible for the continued occurrence of mine explosions. The lack of discipline in the mine, bad practices of miners, inefficient management on the part of mine officials and even the prevalence of strikes have been referred to as producing conditions that bring about mine explosions.

While all of these items have their place and contribute to disaster to a greater or less extent, I cannot regard them as being chief causes of explosions. If military discipline prevailed in a mine, that would not prevent an explosion of gas or dust if the ventilation was insufficient and the air current not properly conducted through the workings, so as to keep the places clear of gas and safe for work.

Numerous efforts have been made by the government to ascertain just the conditions under which explosions take place and to find a remedy for their occurrence. It seems to me, however, that many of these efforts have been wasted. To my mind, instead of training men so largely in rescue work, why not start at the other end and take means to urge the need of better ventilation.

NEED OF A BROADER VIEW OF SITUATION

It would seem almost as if we had concluded that the occurrence of explosions in mines is part and parcel of the coal industry. Now, I am a great believer in first-aid training and rescue work; but let that have its place and let us give greater heed to ventilating our mines in a way that will make them immune to such occurrences.

Perhaps I am wrong, but it seems to me that we do not regard the situation as broadly as we should. I am reminded, just here, of a story told me when I was a boy. A mule crossing a bridge spied a knothole in one of the planks near the side of the bridge. The mule imagined that he could fall through that knothole and, to avoid the danger, ran sideways till he fell off the other side of the bridge and was drowned.

We sometimes become so absorbed in our study of certain methods, that we fail to heed more important things that should receive our attention. Like the mule, our eyes are riveted on the knothole. For my part, I do not believe that mine explosions are a necessary part of the work of mining coal. I believe that, with good ventilation and more uniformity in our mining laws in the different states, explosions in mines can be eliminated.

Parnassus, Pa.

C. W. ATKINS.

Inquiries Of General Interest

Essential Requirements of the Hydraulic Ram

Province of the Hydraulic Ram—Energy
of Flow in the Drive Pipe Proportioned to
the Ratio of Pumping Head to Supply Head

WE HAVE made several attempts to install a hydraulic ram for the purpose of forcing water from a supply basin located about 50 yd. distant and lifting it into a tank elevated 40 ft. above the ground. A pump was formerly used to pump the water from this reservoir into the tank, which forms the main supply at the plant. To avoid the necessity of operating this pump we desired to replace it with an automatic ram, which is not wholly satisfactory.

The surface of the water is from 6 to 8 ft. above the ground where the ram was placed, and the lift to the surface of the water in the tank is 40 ft. We used a 2-in. pipe to conduct the water from the supply basin to the ram and the same size of pipe is used to carry the water from the ram up into the tank. I should state, here, that the supply pipe is carried over the dam of the reservoir, instead of being laid in a ditch, and, on this account, the pipe line acts as a siphon at that point. I want to ask if that hinders the action of the ram. Also, kindly explain what are the essential requirements for successful operation.

—, Ky.

MINE SUPERINTENDENT.

In regard to the siphoning action, at the head of the supply pipe where it is carried over the dam, the only effect is to increase the pipe resistance by reason of its increased length. The effective head in the drive pipe is the same as if the line of pipe was straight. The head is measured, vertically, from the surface of the water in the reservoir to the level of the overflow valve, as indicated in the accompanying figure. As a result of increasing the length of the pipe by carrying it over the dam, the velocity of the flow in the drive pipe is decreased slightly. It is assumed that all the joints are airtight and the mouth of the pipe is fully submerged.

The province of a hydraulic ram is to furnish a means of lifting water automatically through a height greater than the supply head. This is accomplished by utilizing the energy of the water flowing in the drive pipe under gravity, by transmitting that energy to the water in the column pipe. In the figure is shown a diagrammatic elevation of the arrangement of a

hydraulic ram with reference to the supply basin, to which it is connected by the drive pipe. The pipe should have an inclination of, say not less than 1 in 6. Too small an inclination will reduce the efficiency of the operation, while too great an inclination causes too great a strain on the pipe and the valves.

The action of a hydraulic ram is wholly automatic when the two valves have been properly adjusted to suit the conditions. It will be observed that the overflow valve *A* acts upward, in closing; while the discharge or clack valve *B*, at the foot of the air chamber, acts downward, in closing. At the start, the overflow valve is open and the discharge valve shut, these positions being due to the gravity of each valve. The water flowing from the supply basin through the drive pipe escapes through the overflow valve, until the increasing velocity closes that valve suddenly. The impetus of the entire mass of water in the drive pipe, at that moment, acts to force the discharge valve upward, against the pressure and head of water in the air chamber and some of the water enters the air chamber. The action is only momentary, however, and the compression of the air in the chamber overcomes the impetus of the water and again closes the valve *B*. In the recoil that follows, the overflow valve *A* drops and water again escapes at that point, until its velocity is sufficient to force the valve upward, closing it as before and repeating the rush of more water through the discharge valve into the air chamber.

The connection of the column pipe with the air chamber is indicated by the dotted circle near the

DIAGRAM ILLUSTRATING THE HYDRAULIC RAM

bottom of the chamber. At this point, there is another valve not shown in the figure. This is a check valve, acting to prevent any back flow of water from the column pipe into the chamber. It will be understood that the compression of the air in the air chamber acts to force the water from that chamber into the column pipe at each throb or stroke of the system, the closing of the discharge valve *B* being immediately followed with the opening of the check valve at the foot of the column pipe.

The successful operation of a hydraulic ram depends largely on the correct adjustment of the overflow valve. The weight of the valve is partially supported by a spring or counterpoise that enables the valve to act freely between the atmospheric pressure and its gravity and the impetus of the rushing water escaping at that point. The length of the drive pipe plays an important part, by reason of its greater or less resistance to the energizing flow from the supply basin to the ram.

The ratio of the delivery head to the supply head must be proportioned to the length of pipe, this ratio

decreasing as the length of drive pipe increases. In practice, the ratio of the delivery head to the supply head may vary from, say 5 to 10, depending on the length of drive pipe. A common rule for determining the diameter of drive pipe required, for any given quantity of water desired, is to multiply the required quantity of water to be delivered (gal. per min.), by the ratio of the delivery head to supply head and extract the square root of $\frac{1}{2}$ of the product.

For example, in the present case this ratio being $40/8 = 5$, for a delivery of, say 100 gal. per min.,

the required diameter of drive pipe would be $d = \sqrt{\frac{1}{2}(5 \times 100)} = 6\frac{1}{2}$ in. It is well to make the diameter of the delivery pipe from 0.4 to 0.5 times that of the drive pipe, giving in this case, say from $2\frac{1}{2}$ to 3 in. We would suggest using, in the present case, a 6-in. drive pipe and a 3-in. delivery pipe, for a flow of 100 gal. per min. into the tank.

The hydraulic ram is so wasteful of water that it cannot be recommended for pumping, except where the supply of water is inexhaustible. The water pumped rarely exceeds 10 per cent of the flow from the basin.

Examination Questions Answered

Mine Foremen's Examination, Olympia, Wash., Aug. 1, 1921

(Selected 1st-Class Questions)

QUESTION—A seam pitching 27 deg. 30 min., has a slope driven for a depth of 2,655 ft. on the seam. The elevation of the top of the coal, at the slope mouth, is 1,910 and the surface elevation directly over the bottom of the slope, is 1,872 ft.; what is the cover over the bottom of the slope?

ANSWER—The vertical fall of the slope, from its mouth to the bottom, is $2,655 \times \sin 27^\circ 30' = 2,655 \times 0.46175 =$ say 1,226 ft., which makes the elevation at the foot of the slope $1,910 - 1,226 = 684$ ft. Then, subtracting the elevation on the top of the coal at the slope bottom, from the surface elevation above that point, gives for the depth of cover at the foot of the slope $1,872 - 684 = 1,188$ ft.

QUESTION—What are the essentials in pillar drawing to insure safety and economy?

ANSWER—In planning the work with reference to the safe and economical drawing back of the pillars, due regard must be had for the relative width of pillar and opening, which must be determined by a careful study of the conditions relating to roof, floor and seam, including the depth of cover, thickness and inclination of the seam and the possible presence of gas and water or slips and faults in the strata. The pillars must be of such a size as to avoid the occurrence of a squeeze, which would crush the pillars and make their extraction difficult and dangerous. Only experienced men must be employed in the work of drawing pillars. If gas is present in the roof or floor care must be taken to avoid danger from its accumulation on the falls and only safety lamps or electric cap lamps must be used. Before the work of drawing pillars, in a section of the mine, is completed, the possible effect on adjoining sections and on the surface must be carefully studied. It is important to keep the breakline across the ends of the pillars in a practically straight line.

QUESTION—How many tons of coal is there in a room 325 ft. long and 22 ft. wide, on a seam of coal 4 ft. 8 in. in thickness?

ANSWER—Not knowing the specific gravity of the coal, which may vary from 1.2 to 1.5 or more, it is only possible to assume an average weight of 1.3 \times

$62.5 = 81.25$ lb. per cu.ft., for this coal in the solid. The cubic contents of the room is $22 \times 325 \times 4\frac{2}{3} = 33,366\frac{2}{3}$ cu.ft. Finally, the weight of coal filling this space, on this assumption, would be $(81\frac{1}{4} \times 33,366\frac{2}{3}) \div 2,000 = 1,355$ tons. Or, assuming a weight of 80 lb. per cu.ft. for the coal, making $2,000 \div 80 = 25$ cu.ft. per ton of coal, the weight of coal, in the solid, in this room, would be $33,366\frac{2}{3} \div 25 = 1,334\frac{2}{3}$ tons.

QUESTION—What would you suggest to prevent, as much as possible, accidents from the following causes: (a) Falls of rock and coal; (b) mine cars and haulage; (c) injuries from shots and gas?

ANSWER—(a) To reduce to a minimum accidents from falls of rock and coal, there is needed careful instruction of the miners and close supervision of their work, during working hours; careful inspection of each working place; and maintaining discipline in the mine, by suitable punishment for any violation of mine rules and regulations or disobedience of orders. An ample supply of posts and cap-pieces of the proper size must be kept on hand and ready for use in every place.

(b) To reduce the number of accidents from the movement of cars in rooms and on haulage roads, no cars must be left standing where they will obstruct haulage on the main roads, or where they will be in danger of getting loose and running out onto the main track. Careful instructions must be given to the men in respect to cars left at the faces of rooms, or on side tracks, to make sure that they will not be moved from their position. Separate travelingways must be provided so that men will not be compelled to travel the main roads on their way to and from work. Where this is necessary, shelter holes must be provided and kept free of all obstructions, at regular short intervals on roads where rooms are not turned. All haulage roads should be provided with an ample clearance on at least one side of the track and continuous on that side. A carefully arranged schedule should be maintained providing for the movement of loaded and empty trips and a good signal system should be installed between the shaft bottom and inside partings. In slope haulage and on all inclines where cars must be hoisted or lowered, care must be taken to avoid accidents from the breaking of ropes or cars getting loose and running down the incline.

(c) To reduce the number of accidents in shotfiring and from the presence of gas, a careful inspection of the mine and working places must be maintained. The work must be done by competent shotfirers and fire-bosses and the former should be authorized to examine and pass on all holes drilled by the miners. The safest practice is to authorize the shotfirers to charge and fire all shots that in their judgment are safe, after the men have left the mine, examining every place for gas before firing a shot therein.

Steinmetz, Electric Wizard, Dies Suddenly

Dr. Charles Proteus Steinmetz, electrical scientist, died at his home at Schenectady, N. Y., Oct. 26. His death was due to heart failure brought on by a physical breakdown following a recent trip to the Pacific coast which overtaxed his vitality. For the last two weeks he had been under the care of a physician and nurse, but was regarded by them as doing well and as making progress toward complete recovery.

Charles Proteus Steinmetz was born in the old city of Breslau, in Silesia, on April 9, 1865. He obtained his education in the common and high schools of Breslau and in the famous university in his home town. He fitted himself for astronomy in the university at Breslau, but in the autumn of 1888 entered the great polytechnic school at Zurich, and studied mechanical engineering, turbines, steam engines, bridge construction and other such subjects. The next year he and an American fellow student with whom he had roomed came to America in the steerage of a French liner.

Soon after landing he obtained employment at Yonkers, N. Y., as a draftsman, at \$12 a week, in the office of Rudolph Eickemeyer, electrician, meantime pursuing his studies, at night, and writing scientific papers for the press.

CHARLES P. STEINMETZ

A few years later, in 1892, the establishment for which he was working was acquired with various others by the General Electric Co., and he was sent to Lynn, Mass., by that concern to have charge of one of its plants there. Thence, on Jan. 1, 1893, he was transferred to headquarters at Schenectady, as the chief consulting engineer of the General Electric Co., a place which he filled for the remainder of his life and in which his chief work was done and his most important inventions were made. In 1902 he became also professor of electro-physics in Union University, and continued in that office until his death. In 1912 he was appointed president of Schenectady Board of Education, and in 1915 was elected to the Common Council on the Socialist ticket. Last year he was the candidate on the Socialist ticket for State Engineer and Surveyor.

He was for a time president of the American Institute of Electrical Engineers, and was a member of numerous scientific and educational organizations. Harvard gave him an honorary A.M. degree in 1902, and Union University a Ph.D. in 1903.

He never married. In stature he was almost a dwarf, but he had a massive head and brilliant eyes, commanding the attention of everyone who saw him. His special interests in electrical science were magnetism, the symbolic method of alternating-current calculations, and transient phenomena; but there was scarcely a detail of any branch of electrical science, of astronomy or of mathematics with which he was not conversant in masterly fashion. His writings were voluminous.

The body of Dr. Steinmetz lay in state at his home Sunday. Burial took place Monday afternoon, after private funeral services, at Vale Cemetery in a plot which the inventor acquired several years ago. The Rev. Ernest T. Caldecott, pastor of All Souls' Unitarian Church, officiated at the services, assisted by the Rev. Dr. A. W. Clark.

Miners' Union Again Victorious In Coronado Case

Interstate Trade Conspiracy Not Proved, \$700,000 Verdict Voided—Individual Acts Do Not Make Organization Guilty—Case to Be Appealed

Under instructions from Judge John C. Pollock, a verdict for the defense was returned Oct. 27 in the U. S. District Court at Fort Smith, Ark., in the suit of the Coronado Coal Co. and associated corporations of the Bache-Denman Coal Syndicate against the United Mine Workers of America, in which damages of \$2,222,000 were sought as a result of alleged property loss and resultant interference with non-union mining in the Hartford Valley coal field of Arkansas in 1914. Henry S. Drinker, of Philadelphia, was counsel for the plaintiffs, and Henry Warrum, of Indianapolis, presented the union's case. The trial lasted two weeks.

This is the second victory for the miners' union, the U. S. Supreme Court having ruled last year that in the first trial, which resulted in a verdict of approximately \$700,000 for the plaintiffs, the coal companies had failed to establish a basis for the suit under the Sherman law, and ordered a new trial.

Judge Pollock held that the evidence had failed to establish a direct purpose to interfere with interstate commerce, but rather a conspiracy to prevent the operation of the mines as non-union workings. The ruling also pointed out that under the constitution of the United Mine Workers no individual can bind the entire organization; that until the executive board acts no one is bound except individuals who may be involved in any activity, and upon that ground he held that the International union was not shown to be bound by the acts of those responsible for property damage during the strike.

"Before the plaintiffs can ask for a verdict against the defendants or any of them," Judge Pollock said in directing the verdict, "they must establish a conspiracy to do what was done; they must establish that everyone against whom they ask judgment and a verdict knowingly participated in what occurred; they must establish not only that property was lost through the conspiracy but that the conspiracy was formed for the direct purpose of restraining or monopolizing interstate commerce.

"Almost every act affects interstate commerce. It was never the intention of Congress that anything except something directly interfering with interstate commerce should be taken out of the state jurisdiction. We must always have a line of demarcation. The Supreme Court, on much the same evidence, had placed this case on one side."

Judge Pollock held that the mining of coal is not interstate commerce and the fact that it may be shipped later in interstate commerce does not alter the situation.

On the question as to whether the evidence connected the general organization—the International union—with the Hartford Valley troubles, Judge Pollock said:

"They have the right to unionize the entire country. Not only have they unionized the coal miners of many states, but the evidence in this case shows they have members in foreign countries. Before they ask any one to become a member, he has a right to say: 'What obligation am I taking? On what terms? What powers have they to bind me to what they do, or to bind any money I have contributed?'"

"They have put these powers into the constitution and the Supreme Court has construed that constitution to mean that whenever the executive board representing all of them, put there for that purpose—that whatever they do binds every one of them. Until they do act, no one is bound but the individual. The international union is not bound."

Somewhat of a sensation was created when the plaintiffs produced as a witness Oct. 22 James McNamara, "captain" of the attacking forces which in 1914 drove the non-union miners from the field and caused the complete shut-down of the Bache-Denman Coal Co. properties in the Hartford Valley district.

McNamara was on the stand two hours, telling in detail of the alleged conspiracy to forcibly eject from the Hartford

Valley workmen and guards of the Bache-Denman company and to burn and dynamite the property. He told of speeches made prior to the trouble by himself and others. All of the speakers urged that the miners use no violence, but to go peaceably and persuade men at the mine to come out and join the union.

"What was the purpose of the speeches?" he was asked.

"To keep public opinion on our side," was the answer. "And, in case there should be any violence, to show that we went down there to get the men to join the union. I know that this is a practice everywhere when the mine workers have trouble with operators."

McNamara told of conversations with John P. White, International president of the United Mine Workers in 1914. P. R. Stewart, then district president, said, according to McNamara, "that he and White had arranged a plan to prevent Bache from producing coal." The witness, who served a two-year sentence following the Hartford Valley troubles on a plea of guilty to conspiracy to violate a federal injunction, said that he had been working as a non-union miner most of the time since he had been released from prison.

Pete Hanraty, former president of District 21, was another interesting witness for the plaintiffs. The former union official testified that it had been his practice as district president to notify International officers when an operator attempted to operate on the open-shop plan, because, he said, "it involves every district and the International because an open-shop or a non-union mine can produce coal cheaper than a union mine. If allowed to go on it is only a question of time until the union would go out of existence."

Roland Ford Barns, captain of mine guards; English Daugherty, 66-year old victim of an attack on the Prairie Creek mine, July 17, 1914; M. W. Weston, who operated a slope mine near the scene of the trouble in 1914, and U. S. Judge Frank A. Youmans were other witnesses for the plaintiffs.

Henry Warrum, defendant counsel, offered several objections to testimony presented by the plaintiffs, claiming that the higher courts had previously held that the identical testimony did not establish the grounds which the plaintiff claimed, but Judge Pollock overruled the objections.

Notice was given that the case would be appealed.

Union Combats Co-operative Mining Movement in Southwest

Operation of several mines in the Kansas field during the summer by miners on a co-operative basis has aroused union officials to an effort to stop what they term a drift toward the open shop in District 14. Meetings are being held at various towns in the district each Sunday and the miners are being exhorted to take no part in any operations that have not the union's sanction.

The first of these meetings was in Liberal, Oct. 21. There a resolution was adopted to the effect that the members regretted "any and all propositions along the line of co-operative or any other method than the joint agreement now in effect between operators and miners." The local pledged itself to work among other locals of its section to "secure their assistance in stopping the miners in this end of the field who are operating outside our organization."

BIDS OPENED by the U. S. Shipping Board on Oct. 25 for furnishing and delivering f.a.s. vessels New York harbor on Oct. 27 1,800 gross tons of either Pool 9 or Pool 71 bituminous coal brought prices from ten dealers, ranging from \$4.18 to \$5.25 per gross ton, or on a basis of about \$1.02 to \$1.97 per net ton f.o.b. mine. The contract was awarded to the Rhodes Fuel Co., the lowest bidder. Bids opened by the Board on Oct. 15 for the same quality of coal resulted in offerings ranging from \$4.47 to \$5.25 per gross ton.

PLANS FOR THE ANNUAL CONVENTION of the United Mine Workers of America will be considered at a meeting of the International executive board to be held Nov. 13 at 10 a.m. in Indianapolis, at the call of John L. Lewis, international president. Other matters, including the recent strike in the anthracite fields in Pennsylvania, will be considered by the board, which probably will be in session for a week or more. Plans for increasing the membership also will be discussed. The international convention will be held in January. At this meeting a tentative wage scale will be submitted to the membership in lieu of the present one, which expires April 1 next.

Wide-Margin Sales of Anthracite Waning, Says Trade Commission

Handling Charges by Wholesalers Shrinks from \$1 in Some Instances to 25c.—Resumption of Mining Disperses Panic Demand

"Anthracite wholesalers," says the second report of the Federal Trade Commission on anthracite, released Oct. 29, 1923, "are required to report to the Commission, as to domestic sizes only, their sales of premium or unusually high-priced coal. While excessive wholesalers' margins and scalping by wholesalers strongly tend to the undue enhancement of anthracite prices, an even more significant and equally objectionable cause of high prices is found in the exorbitant prices charged by some of the producers.

"Among these producers there is a very wide variation in the prices of coal at the mine, as shown by the reports made by the wholesalers to the Commission. The following tabulation shows for premium coal the proportion of carloads at different prices paid by wholesalers, for purchases from operators f.o.b. mine, for the week ending Oct. 6, 1923:

Price Range per Ton, f.o.b. Mine	Per cent
\$9.50-\$9.99	6.7
10.00-10.99	45.5
11.00-11.99	13.8
12.00-12.99	33.4
13.00 and over6
Total	100.0

"With respect to such premium coal, the reports obtained from wholesalers show that they paid in excess of \$11 per ton for nearly 48 per cent of the prepared sizes of anthracite purchased directly from a producer, and over \$12 per ton for more than one-third of such purchases.

"While the Commission has not yet made inquiry from the mine operators regarding their selling prices and cannot state, therefore, the proportion of high-priced or premium coal sold by all operators, it is a matter of common report that some of the larger companies are charging from about \$8.75 to \$9.25 per ton f.o.b. mine for domestic sizes, while other companies, as shown above, are sometimes charging over \$13.

"Such wide differences in prices in the present period of normal operation of the mines are neither reasonable nor necessary, and often become the cause, but still more often the excuse, for the excessive prices now being extensively charged to the consumer."

With respect to gross profits or margins of wholesalers, the report says that for each of the weeks ending Sept. 29 and Oct. 8 the number of cars of anthracite of domestic sizes reported as having been sold at \$10 or more per ton for nut and larger sizes, and \$8 a ton for pea coal, was more than double the number reported for the week ending Sept. 22. The Commission declares this increase was due primarily to the larger volume of coal handled after the resumption of mining following the strike.

"As stated in the previous report," says the Commission, "there was a marked tendency for wholesalers to add 25c., 50c., 75c. or \$1 per ton to the price paid for coal handled, more often than to add intermediate amounts. There was, however, a tendency for the percentage of sales on which 50c. or more per ton was added to decrease. At the present time 25c. appears generally to be regarded as a reasonable amount per ton to be added by wholesalers regularly handling company coal.

"For the week ending Sept. 22 wholesalers added 50c. or more per ton to the price on 66 per cent of all car sizes reported. During the following week the percentage on which 50c. or more per ton was added decreased to 47 per cent, and during the week ending Oct. 6 it dropped to 38 per cent.

"With the falling off in sales at high margins, there were decided increases in the number of sales made at a spread of 25c. per ton. Sales at a 25c. spread represented 31 per cent of the total for the week ending Sept. 22, and nearly 43 per cent for the week ending Oct. 6. The general

tendency shown is for the high speculative margins taken on domestic sizes during the week ended Sept. 22 to decrease as the anthracite mines resume production, as the panic demand of consumers and retailers for coal at any price subsides somewhat and as effective publicity is given to the facts.

"Sales of steam sizes, which wholesalers are requested to report irrespective of price, were made at margins markedly lower than those on high-priced domestic sizes. The bulk of sales of steam sizes in all three weeks were made at margins not exceeding 25c. a ton, with a small percentage of sales in each week made at purchase cost, or less than cost, to the wholesaler.

"The largest per ton loss reported during the three weeks was 55c. a ton on one car of steam coal. Such sales are frequently pointed out by wholesalers as a justification for high margins on domestic sizes. As affecting all sales of steam coal and high-priced sales of domestic sizes covered by reports to the Commission, however, they represent but six-tenths of 1 per cent of the sales reported for the week ended Sept. 22; only 1.5 per cent for the week ended Sept. 29, and 3.9 per cent for the week ended Oct. 6. Losses on such a small percentage of total sales cannot justly be used as an excuse for the high margins taken on domestic sizes."

Coke Output in 1922 Lowest of Any Year Except One Since 1911

Total output of coke in 1922, according to final statistical returns by the Geological Survey, was 37,124,012 net tons, comprising 28,550,545 tons of byproduct and 8,573,467 tons of beehive. Preliminary estimates made in February were substantiated by the final returns from producers. Except in 1921, when business was extremely depressed, each year since 1911 has witnessed a larger total output of coke than 1922. The production of beehive coke was the smallest since 1888, except that in 1921. The output of byproduct coke, however, was the largest recorded since the beginning of the industry, except only that in 1920. As compared with 1920, the last normal year, 1922 showed decreases of 29 per cent in the total production of coke, 8 per cent in byproduct coke and 58 per cent in beehive coke.

Byproduct coke continued to exceed beehive coke in quantity, as it has since 1918. Only 23 per cent of the total came from beehive ovens in 1922, against 22 per cent in 1921 and 40 per cent in 1920.

SALIENT FIGURES OF THE COKE INDUSTRY IN 1922

	Beehive	Byproduct	Totals
Ovens in existence Dec. 31, 1922.....	63,957	11,212	75,169

Sold: Quantity (net tons).....	41,533	526,157	567,690
Value.....	\$132,448	\$1,583,399	\$1,715,847

The trend of production during the year, as shown by the monthly output, was in the main upward. The year opened with the rate of production higher than in 1921, but nevertheless abnormally low. Production of beehive coke increased from January to March and then slumped during the coal strike. Beginning in October, a rapid rise brought the rate at the end of the year to nearly two and one-half times that at the beginning. Production of byproduct coke declined slightly in February and then gained gradually through June, despite the coal strike. It slumped again in July and reached a low point in September, but increased to unprecedented quantities in November and December.

The following final figures of the production of coke by months are based on complete returns from coke manufacturers. They are somewhat greater than the preliminary

estimates issued currently during the year, which were based on railroad records of shipments.

MONTHLY PRODUCTION OF BEEHIVE AND BYPRODUCT COKE, 1922
(In Net Tons)

Month	Beehive	Byproduct	Totals
January	529,000	1,886,000	2,415,000
February	586,000	1,800,000	2,386,000
March	781,000	2,137,000	2,918,000
April	564,000	2,206,000	2,770,000
May	465,000	2,544,000	3,009,000
June	491,000	2,594,000	3,085,000
July	476,000	2,501,000	2,977,000
August	567,000	1,822,000	2,389,000
September	649,000	2,249,000	2,898,000
October	935,000	2,812,000	3,747,000
November	1,214,000	2,931,000	4,145,000
December	1,316,000	3,069,000	4,385,000
Totals	8,573,000	28,551,000	37,124,000

The value of all the important byproducts from coke-oven operations recovered and sold during 1922 was \$83,387,763. This amount, however, does not represent the total value of all byproducts, as a large part of them, particularly the gas, was used in the plants where manufactured. The following table summarizes the total production and sales of these byproducts. The quantities given are smaller than appeared probable from the quantity of coke reported to the Survey currently during 1922, and the estimates prepared early this year were therefore higher than these final figures.

BYPRODUCTS OBTAINED FROM COKE-OVEN OPERATIONS IN 1922

Product	Unit	Production	Quantity	Sales	
				Total	Average
Tar	Gallons	327,779,734	162,204,417	\$6,419,743	\$0.0396

^a Includes gas wasted and gas used for heating retorts.

^b Of this amount 98,432,100 gallons was refined on the premises to make the derived products listed.

Statistics compiled by H. L. Bennit, Geological Survey, Washington, D. C., Aug. 31, 1923.

THE NATIONAL RETAIL COAL DEALERS' ASSOCIATION has named S. B. Crowell, president of the association; M. E. Keig, of the Consumers Coal Co., Chicago, and Roderick Stephens, of New York, to represent the association on an advisory committee of fifteen to co-operate with the Department of Commerce in coal matters. The National Coal Association, the American Wholesale Coal Association, the Anthracite Operators' Policy Committee and the American Railway Association also are to appoint three members each to the committee.

Mine Workers in Southeastern Kentucky Take Wage Cuts to Avert Shutdowns

CHICAGO, Ill., Oct. 29.—Cutting wages back 20 per cent, or to the 1917 scale, is spreading through parts of non-union southeastern Kentucky, especially in Bell County. A number of the lesser operations are reported already on the low scale, operators saying that miners have approved of the cut as preferable to mine shutdowns. The cut is not general nor uniform and is discouraged by such operator groups as the Hazard Coal Operators' Exchange, which met Saturday at Lexington, Ky. Observers declare that in spite of official opposition the reduction is going to reach up into northeastern Kentucky before long by the action of "weak sisters" among mine owners. Low prices and no market are responsible. The miners' union is making a special effort to organize the region.

Springfield to St. Joseph Rate Cut

Lower rates on coal from the Springfield district of Illinois to St. Joseph, Mo., have been prescribed by the Interstate Commerce Commission. The rates from mines on the Alton and the Wabash in the Springfield district are held to be prejudicial to the extent that they exceed by more than 40c. per net ton the rate contemporaneously maintained by these roads to Kansas City. Great interest in this case was evinced by the Southwestern Interstate Coal Operators' Association, the Fifth and Ninth Districts Coal Bureau, by the Kansas City Power & Light Co. and by the Central Illinois Coal Traffic Bureau. There is keen competition between Kansas City and St. Joseph for the location of industries and business enterprises. The freight rate on coal has an important bearing on this situation. Operators in the southern Illinois fields opposed reductions from the Springfield district, without securing a corresponding reduction in the rate from other Illinois fields. Operators in the Kansas, Missouri, Oklahoma and Arkansas districts opposed any reduction unless it should apply also to the Southwestern coal field. These operators contend that they already have lost much business in Kansas City to the Springfield district because of the former reduction and they contended that their coal would be displaced at St. Joseph by this reduction.

THE COAL, COKE & IRON ORE COMMITTEE, CENTRAL FREIGHT ASSOCIATION TERRITORY, announces a hearing Nov. 8, at 10 a.m., at room 606, Chamber of Commerce Building, Pittsburgh, Pa., to consider the proposed cancellation of proportional rates on bituminous coal in carload lots from mines in Ohio and the Inner and Outer Crescents of Pennsylvania, Virginia, West Virginia, etc., to upper Mississippi River crossings, for beyond. The committee also will hold a hearing at the same time and place on the proposed cancellation of rates on coke (except petroleum, creosote and tar or pitch coke), coke breeze, coke dust and coke screenings, in carload lots, from ovens on the Chesapeake & Ohio Ry. in the New River, Kanawha, Kentucky and Big Sandy districts, to stations in Ontario and Nova Scotia—i. e., Amherst, N. S.; Owen Sound, Sudbury, Copper Cliff, Victoria Mine, Sault St. Marie and Worthington, Ont.

AT A RECENT MEETING on standardization of anthracite sizes of subcommittee IV of Committee D5 on Coal and Coke, American Society for Testing Materials, held at the office of Hubb Bell, chairman, it was decided tentatively to adopt the following sized screens for anthracite, and to submit the same to producers for their action: Broken, through 4½ in., over 3½ in.; egg, through 3½, over 2½; stove, through 2½, over 1½; chestnut, through 1½, over ¾; pea, through ¾, over ½; buckwheat, through ½, over ¼; rice, through ¼, over ⅛; barley, through ⅛, over ⅜ or ⅞; culm, through ⅜ or ⅞ in.

I. C. C. Likely to Modify Ruling on Private Cars; Railroads Make Poor Case

Lacking New Evidence, Carriers Reiterate Old Arguments—Personal Opinions but No Facts or Figures Presented—Commission Points Out That Case Involves Transportation, Not Merchandising, Problems

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Judging from questions asked and from the attitude of the members during the rehearing of the assigned-car case, there is some likelihood that the Commission will modify its recent opinion so as to grant a concession to the owners of private cars. It also is regarded as probable that the Commission will defer the effective date of its order from Dec. 1 to Jan. 1. It is the consensus of opinion that no change will be made in that portion of the opinion affecting the preferential use of cars for the procurement of railroad fuel.

The railroads have made a particularly poor case. Even the Chesapeake & Ohio, which clamored loudest for a rehearing of the case, failed to bring in a scintilla of new matter. Railroad witnesses generally simply reiterated arguments which had been presented at the former hearing. Boiled down, the substance of their arguments is that assigned cars are necessary to insure the railroads with a continuous supply of the type of coal best adapted for locomotive purposes. Their statements, however, were presented as personal opinions, and no convincing facts and few figures were presented in the effort to substantiate the statements. Many of the railroad witnesses were purchasing agents or those concerned with the use of fuel. Members of the Commission pointed out repeatedly that the case presents transportation and not merchandising problems.

When the railroads announced, after having presented only perfunctory testimony, that they had completed their case, those in attendance were astounded. No explanation is forthcoming as to why they asked that the case be reopened when they had no new evidence to present. Even Commissioner Aitchison admonished the railroads that a new opportunity had been afforded them to present evidence and urged them to present it if they had it.

RAILROADS OVERCONFIDENT AT FIRST HEARING

It is believed the granting of the rehearing was influenced in no small degree by a feeling on the part of members of the Commission that the railroads had been overconfident during the first hearing. It was assumed that the railroads took it for granted that the Commission would not abolish assigned cars and as a consequence did not make a determined effort to present arguments in favor of the continuance of their use. The showing during the rehearing, however, indicates that the railroads are not in a position to substantiate the claims they have been making in this particular.

That the desire on the part of the railroads to continue assigned cars was actuated more by the better prices they could obtain by furnishing full car supply to the mines with which they had contracts, was emphasized in an amusing way during the hearing. One of the witnesses was making certain points contained in a letter written by an official of the Frisco lines. Opposing counsel happened to ask to see the letter. The witness showed disinclination to comply with the request. Finally he tendered the first page of it. He was asked for the remainder of the letter, which he declined to hand over. Commissioner Aitchison was called upon to rule on the matter. He held that it had been the practice of the Commission to allow opposing counsel to consult a full document when extracts only were being presented. When, under that ruling, the whole letter was passed over, it was found that the railroad official had emphasized the need for assigned cars because of the effective

way in which they could be used to obtain lower prices for coal.

The arguments made by the railroads as to the strides they are making in operating efficiency failed to square with those which were presented at this hearing to indicate the inability of the roads to obtain ample fuel without a preferential car supply. Another interesting point brought out was the large acreage of undeveloped coal mines owned by railroads. The New York Central alone, it was testified, owns 100,000 acres of potential coal lands.

Another point which can be deduced from the testimony is the comparatively small amount of coal which moves in private cars during the period when there is any stringency in car supply. The total probably does not reach 10,000,000 tons on an annual basis, an insignificant amount when compared with the total yearly movement.

DISCLAIM DESIRE FOR PREFERENTIAL TREATMENT

Those arguing for private cars disclaim any intention of desiring preferential movement or placement. They ask, however, that they be allowed to use these cars during a period of car shortage, provided the railroads have adequate motive power, terminal facilities and other means of handling them without prejudice to shippers who use system cars. It is this amendment which the Commission is thought likely to embody in an amended opinion. The argument against such a concession is that it would be difficult to determine just when the supply of motive power is adequate and just when terminal or junction facilities are sufficiently open to handle the excess of cars. The policing of such a regulation would be difficult especially when the natural tendency on the part of the carrier would be to take on all tonnage offered. It is argued further that even an impartial judge would have a highly technical and delicate question to decide just when the use of private cars would not constitute a discrimination against the shipper in system cars.

PRIVATE CARS HAVE INDIRECT BENEFIT

The point was emphasized by witnesses on behalf of the owners of private cars that the advantages of their use is an indirect one. Their actual operation results in a loss. For that reason it is contended by those opposing private cars that the advantages are sufficient to justify the continuance of their use even were the decision of the Commission to stand in its present form. There will be no trend, it is contended, to sell these private cars, so that they will not be forced on to a market in which there is only one bidder.

The fact that Commissioner Aitchison assured an intending buyer of private coal cars that he had at that time no reason to believe the policy toward them would be changed carries with it no moral obligation on the part of the Commission, it is contended. One man frequently asks another as to the advisability of purchasing a certain stock. The intending purchaser may act on the opinion and buy. Subsequently the price of the stock may fall, causing a loss to the purchaser. Such incidents are daily occurrences, but there is no thought that the man who proffered his best judgment should share any portion of the loss. It is held that all Commissioner Aitchison did, in an effort to be helpful and friendly, was to give his inquirer the benefit of his judgment.

Production and the Market

Weekly Review

Production of soft coal continues in excess of consumption and the market is indifferent. The demand for storage coal is falling off and buyers with contracts are slowing up receipts. Some large operators have reduced contract prices in an effort to keep their coal on the move and mines going.

The increase in production of soft coal recorded for the second week in October was only temporary, the report of the Geological Survey showing that the output in the week ended Oct. 20 was 10,675,000 net tons, a decline of 278,000 net tons from the week ended Oct. 13 and 24,000 tons less than in the week ended Oct. 6. A further decline is indicated for last week. Complete returns show that the production of soft coal in September was 42,216,000 net tons, a decrease of 2,648,000 tons when compared with August.

Prices for soft coal continue to move downward, *Coal Age* Index registering 184 on Oct. 29, a drop of two points from the previous week. The average price was \$2.23. Increases in southern Illinois, Springfield, western Kentucky, Clearfield, Cambria and Somerset coals were offset by declines in Standard, southeastern Kentucky, Pittsburgh, Kanawha and Pocahontas coals.

PRODUCTION LIMITED BY DEMAND

Lack of demand is the dominant factor in limiting production. In the Middle West the trade was aroused by a change in temperatures which created a slightly better demand for domestic coal. Steam coals continue hard to move. In St. Louis the market is quiet with the cheaper domestic coals in better demand than the better grades. No indication of improvement is seen in New England, where reserve coals are piling up and Pennsylvania coals move slowly.

In Ohio there was a slight upturn in domestic coals but there is no activity in the steam situation, users of these coals having from four to six weeks' supply on hand. Not so much coal moved in the Pittsburgh dis-

trict at the extreme low prices, giving the indication that the market now is in a slightly better condition.

Heavy buying of Welsh anthracite is reported, orders aggregating about 140,000 tons, nearly all of which is for Boston delivery, having been placed last week with Welsh mine operators and exporters.

Lake dumpings of soft coal increased during the week ended Oct. 22 to more than 1,000,000 net tons for both cargo and fuel coal.

	Week Ended Oct. 22	Season to Oct. 22
Cargo	955,551	24,571,917
Fuel	54,571	1,340,969
Totals	1,010,122	25,912,886

Production of anthracite is nearly up to capacity, 2,045,000 net tons having been mined during the week ended Oct. 20, an increase of 36,000 tons when compared with the previous week. Due to observance of Mitchell Day, Oct. 29, by the mine workers output will show a decrease this week. Brisk demand for the domestic sizes continues, with stove and chestnut leading. Egg, pea and buckwheat are accumulating on the Duluth docks, stove and chestnut sizes moving rapidly.

There is little activity in the export market. Some orders were placed but the tonnage was small. At Hampton Roads, dumpings during the week ended

Estimates of Production

(Net Tons)

BITUMINOUS

	1922	1923
Oct. 6	9,736,000	10,699,000
Oct. 13 (a)	10,110,000	10,953,000
Oct. 20 (b)	10,378,000	10,675,000
Daily average	1,730,000	1,779,000
Calendar year	301,239,000	445,801,000

(a) Subject to revision. (b) Revised from last report.

Oct. 25 were 259,158 net tons, as compared with 274,854 tons dumped the previous week, the decrease in shipments to New England and other coastwise points accounting largely for the decline.

Middle West on Slow Upturn

Although Illinois and Indiana mines are working less than half time—many mines a good deal less than that—and, although production has not taken a marked turn for the better, yet domestic demand all around is stabilizing, prices fluctuate less and less from circular levels and there is a slightly better tone to Midwest coal trading. A little cooler weather had an effect on the market. Good southern Illinois lump brings close up to the circular of \$4.35 everywhere but in great centers like Chicago, where quotations must be shaved down to \$3.90 or thereabouts. Central Illinois is moving about all its 6-in. lump output at the circular price of \$3.25, profiting over southern Illinois in many markets by reason of both a favorable freight rate and the wide difference in price.

Indiana is having a little more trouble maintaining its

circulars, but there, too, big lump is showing slight signs of activity. In all fields the middle sizes—egg and nut—are sluggish. Screenings, however, have not been backing up much on the mines even though in most regions less-than-a-dollar prices have practically disappeared. Big buyers of steam coal are inclined to hold out waiting for a drop in screenings when lump demand becomes lively with cold weather.

St. Louis Is Sluggish

Conditions in St. Louis continue quiet. There is little domestic demand and it is for cheaper grades of coal, there being little call for Franklin County and practically none for anthracite, smokeless or coke. Dealers are all loaded up and little is doing in wholesale business. Country trade is somewhat similar, although it is good in spots. Carload steam is unusually slow, but wagonload keeps up fairly good. Country steam is not a factor in St. Louis. A little is moving to the Omaha, Minneapolis and Chicago markets.

Reports from the Carterville field show that there is a further curtailment of production on account of no market and mines continue to suspend operations. All mines have

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

Index	1923				1922
	Oct. 29	Oct. 22	Oct. 15	Oct. 8	Oct. 30
Weighted average price	184	186	185	346	
	\$2.23	\$2.25	\$2.24	\$4.19	

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

no bills on track and some of them seem unable to move any coal at all. Railroad tonnage continues light. The situation in the DuQuoin and Jackson County field is bad.

In the Mt. Olive district things are in a bad way. One mine of the Consolidated Coal Co. at Mt. Olive worked Oct. 5 and not again until the 24th, on account of failure to move the no-bills and scarcity of cars on the Wabash. On the Litchfield & Madison R.R. conditions are extremely bad on account of no cars. In the Standard field, mines are shutting down, there being no market for any size and several working mines are selling coal at a loss. A careful survey of the fields shows that some mines are having a hard time meeting payrolls.

Kentucky Is Stirring

Cold weather throughout the Central West with snow reported in some localities has created a better demand for prepared sizes, and Louisville jobbers and sales offices of mining companies report fair business on prepared coal, some houses showing increased sales over the earlier season, but business is being done on a narrow margin by brokers as well as operators due to the competition for business, good car supply and low prices. Screenings are made in great volume and have to move at give-away prices.

If statements from eastern Kentucky are correct relative to non-union mines cutting back to the 1917 wage-scale

basis, the outlook is poor for union mines in western Kentucky. About the only thing to brighten the outlook is that when the Lake and Northwest trade is supplied a lot of producers of prepared sizes will be forced to curtail, thus reducing overproduction of screenings. Right now there is practically no movement of mine-run, and that at very low prices. Some mine-run in distress has been reported selling at down around screenings prices over the past ten days, but it represented principally off grade stuff.

Practically no new mining ventures are under way in western Kentucky, there being one large stripper project under construction, but otherwise the field is at a standstill as regards development of new mines, although there has been a considerable amount of improvement at old mines to better fit them for supply prepared sizes.

Northwest Shipments Heavier

Shipment of all kinds of coal to the Northwest docks has been steadily on the increase lately, but demand throughout that region has not been stimulated much yet by the approach of winter. Bituminous markets are dull though hard coal and smokeless substitutes are in light demand continually. All-rail screenings in most regions, especially that around Minneapolis and St. Paul, are not so abundant. Stocks there are working off slowly and regular sizes are steadying a little in price.

Shipments to the Head-of-the-Lakes picked up during the week when forty-seven cargoes arrived. Of these eight were anthracite. Report of cargoes on the way from lower Lake ports shows that twenty-seven are coming up with three of hard coal included.

The Duluth market in bituminous is very dull. Everyone is playing a waiting game. Prices in bituminous remain unchanged, but there is every indication that the market will sag by the first of the year unless some spurt of buying commences. Reports of stocks on docks show 5,100,000 tons of soft and 150,000 tons of anthracite. This indicates that coal is piling up.

Increasing receipts by Lake is the only notable feature of the coal trade at Milwaukee. The October record will probably exceed that of any month since July. Receipts of anthracite aggregate 115,485 tons and soft coal 385,619 tons, making the season's receipts thus far 749,124 tons of the former and 2,470,963 tons of the latter. Both wholesale and retail markets are slow.

Cooler Weather Helps West

Cooler weather is having a slight effect on coal trade throughout the West and Southwest but nowhere is there real life to be observed. In Utah some operators assert that a partial shortage of cars is responsible for the short running time of the state, but generally it is admitted that market alone is responsible. Dealers are moving coal steadily, however, though industrial coal drags. In Colorado market improvement is noted, but it is small for this season of the year. Prices continue to bump bottom. Weakness in the demand for screenings is the main deterrent in the Southwest. The Kansas and Oklahoma lump market is fairly good but the mining regions are filling with no-bills of fine sizes.

Slight Upturn in Ohio Markets

Interest in the Cincinnati market is centered around a little upturn in inquiries following a touch of cooler weather. Domestic business was aroused slightly, turned over and then returned to the dragginess that has been noticeable for some time. Meanwhile the price on slack has been dropping and run-of-mine has been growing perceptibly weaker so far as day to day prices are concerned. The smokeless-coal situation continues practically unchanged. Prices of lump are being maintained while the prices for run of mine and slack has been governed in a high degree by the drop in high-volatile coals. For the first time in years sales of smokeless slack were reported around \$1 to wholesale dealers.

Increased demand for domestic coals was noticed in the Columbus market, but steam business continues dull. All heavy consumers appear to be stocked, and fill out by pur-

chasing distress coal. Steam grades are a drug on the market. Utility and railroad requisitions are not as large as they were. Retailers are replenishing their stocks only as needed, and prices are steady.

Retail dealers in the Cleveland market are fairly well stocked, domestic consumers not buying until the coal is actually needed. Steam-coal users have from four to six weeks' supply of coal on hand. Offerings of distress coal are not large, many operators preferring to run their mines from three to four days a week rather than ship their product into the present market. Altogether the trade is not optimistic.

Reports received from 442 mines by the Southern Ohio Coal Exchange show that during the week ended Oct. 13 there was an output of 166,750 tons, while the eastern Ohio field produced 426,000 tons during the week ended Oct. 20.

While the Pittsburgh market is in bad shape it is possible that it is in a slightly better condition than a week or two ago in the matter of price. The full range of quotations is much the same, but in point of tonnage there is not as much going at the extreme low prices as there was. Production, however, is poorer and is decreasing. There is much speculation as to how the market will act when the Lake season ends. It is evident that consumers expect it to be easier, but prices may be too low to stand any further decline. There are some observers who think the market will counter the expectations and grow stronger at the end of the Lake season.

Production in central Pennsylvania is still on the decline. Some operations are working less than half time.

No Improvement Seen in New England

There are no indications of improvement in the New England steam trade. There is constant pressure on consumers to take coal, while reserves generally are nearly as great as in November, 1918. Market cargoes seem to be the rule, and due to heavy receipts by water the range of price on cars at this end is further depressed.

Pocahontas and New River, both No. 1 Navy standard and less choice coals, are selling down to \$4.35 per gross ton f.o.b. Norfolk and Newport News. Prices on cars at Boston are correspondingly low; while some agencies are asking \$6 there is at least one factor who is out for business at \$5.50. Doubtless the latter figure is made to hold trade and does not mean that the same coal at the Virginia terminals is being sold on so low a basis.

In the territory within seventy-five miles of Boston or other tidewater distributing points there is practically nothing doing now on coal all-rail from central Pennsylvania. In that part of New England that is exclusively all-rail very low quotations are heard, but the aggregate tonnage is less than during the summer.

Seaboard Markets Sagging Further

Demand and prices continue on the downgrade in the New York soft-coal market. Bids received by the U. S. Shipping Board for delivering f.a.s. vessels that harbor 1,800 gross tons of either Pool 9 or Pool 71 coal resulted in tenders ranging from \$4.18 to \$5.25 per gross ton, or on a basis of \$1.02 to \$1.97 per net ton f.o.b. mine. Dumpings at the local piers during the first five days of last week averaged around 260 cars daily.

In Philadelphia demand is extremely light and some of the larger users seem content to depend at present on their storage piles. Contract holders are not taking their full requirements and are apparently buying at the present low spot prices. This tendency has grown to such an extent that several large producers have reduced their contract rate of \$3.80 put into effect April 1 to \$3.50, some of them making it retroactive to Oct. 1. This has had a tendency to push prices still further down the scale. The better grades are in best demand. The Baltimore market is more or less spasmodic. Wholesale dealers received many offers from operators, but buying is light.

There was little or no improvement noticed in the commercial coal market at Birmingham but domestic buying picked up slightly last week due to cooler weather. As a result mine orders that were suspended have been reinstated. Lump coal is retailing at from \$7.50@10 per ton.

The soft-coal market at Toronto is bad and there is practically no demand. Pennsylvania smokeless is being quoted at \$7.20 delivered; steam lump, \$7.65, and slack, \$5.75.

Welsh Anthracite May Be Market Factor

Demand for anthracite domestic coals around New York and Philadelphia is centered chiefly around stove and chestnut, but both egg and pea are moving readily and without trouble. Most buyers find it easier to obtain the larger coals if they include in their order some steam size tonnage. While quotations in the New York market range as high as \$12.50 for egg, stove and chestnut, very little coal of that price comes to that market, most of it going to New England and line points, while it is said that Canadian buyers are obtaining tonnages at quotations ranging as much as \$1 less. The large companies and some independent operators are storing the steam coals. Demand for these coals is low and prices far below company schedules.

Dealers in Baltimore complain of the lack of stove coal and are pushing sales of egg, chestnut and pea as hard as possible.

The New England situation is expected to be greatly relieved by receipts of Welsh anthracite, orders aggregating nearly 140,000 tons having been placed last week with a Cardiff house at a price said to be around \$12 c.i.f. Boston harbor. Other quotations for Welsh anthracite range as low as \$11 c.i.f. Boston or New York harbor.

The market for hard coal in Toronto is brisk, and supplies are fair. Retail dealers are selling anthracite domestic sizes at \$16 and are able to fill orders of reasonable size.

For the fourth consecutive week production of beehive coke declined and a new low weekly-record for 1923 was established, says the Geological Survey. The total output for the week ended Oct. 20 amounted to 276,000 net tons, a decrease of 8,000 tons from the previous week, which was confined chiefly to Pennsylvania and Ohio. The Connellsville market is suffering from extreme lightness of demand.

Foreign Market And Export News

British Coal Production at High Level; Welsh Market Still Unsettled

Great Britain's mines continue to produce large weekly tonnages, the output for the week ended Oct. 13 amounting to 5,625,000 tons, says a cable to *Coal Age*. This compares with 5,528,000 tons the previous week, and is the heaviest weekly production since June 16 of this year when it was 5,654,000 tons. It is 370,100 tons larger than the output for the week ended Oct. 14, 1922.

The Welsh coal market maintains its state of unsettlement. Stormy weather has involved serious tonnage delays and mine stoppages have become fairly frequent. Supplies are still pressing heavily on the market, and the excess over demand prevents improvement. France, Italy, Belgium, and South America are buying cautiously, the first three countries being influenced by the Ruhr situation, while coals are making competition in South America very keen.

Welsh operators are disappointed at not being given the contract for 150,000 tons for the Nord and Etat Railways of France. In some quarters the placing of this order in America is regarded as an attempt to "bear" Welsh prices.

Consumers generally are holding their orders to force Welsh prices to a still lower level.

The Newcastle market is in a better position than it has been during the past two months. Inquiry developed so that merchants are directing their attention to November loading, and business is coming forward satisfactorily. Prospects for December are regarded as good.

Hampton Roads Market at Low Point

Business at Hampton Roads last week, was at the dulllest point in the entire year and the price of coal dropped to a point where many shippers were not establishing quotations.

Movement in all directions slackened, particularly in coastwise trade. Bunkers was the only branch of the business that approached any degree of satisfaction. Shippers said that overproduction had flooded the markets with coal, and it might be a long time before it could be moved to a point where

normal conditions could be hoped for.

Fair export movement was noted, though the dumpings at the piers were lower than at any time for many months.

French Coal Market Quiet

The general trend of the French coal market is quiet. Domestic coals are in fair demand, with prices unchanged. The market for British coal is easier and it is obvious that so long as the rate of exchange remains high and unsettled, French consumers will not be inclined to buy on a large scale. Furthermore, the resumption of indemnity deliveries from the Ruhr is shortly expected to become normal.

During the first nine days of October 42,400 tons of coke were shipped from the Ruhr district to the S.C.O.F. This tonnage was taken from the reserve stocks as none of the French production of the occupied area has as yet been delivered.

News Items From Field and Trade

ALABAMA

The Pratt-Warrior Coal Co. is building ten or twelve employee dwellings at its mine near Pumpkin Center, on the Warrior River, and also is erecting a store for the convenience of its employees.

While making an inspection of the Hamilton slope of the Tennessee Coal Iron & Railroad Co., near Pratt City, Oct. 17, J. M. McHugh, general superintendent of mines; G. W. Crane, superintendent Hamilton Slope, and Harvey McCrorie, superintendent of Pratt mines, were painfully burned about the face and upper portions of the body when a pocket of gas was set off by a lamp of one of the party.

The Gulf States Steel Co. has leased from the Pratt-Warrior Co. the mine of the latter at Ivey Bluff, on the Warrior River, in the southern part of Walker County.

ILLINOIS

The Gartside Coal Co.'s mine No. 4 at Murphysboro will be closed down and abandoned, according to information from that place. The entire mine, both top and bottom, including all machinery, equipment, etc., will be dismantled and disposed of. Robert Niggeman is president of the concern.

H. B. Wilson of Herrin, has opened a new strip mine on a farm north of Cambria. The mine is owned and operated exclusively by Wilson.

A voluntary petition in bankruptcy was filed in the United States District Court at St. Louis, Mo., by the Missouri-Illinois Coal Co., listing assets totaling \$151,185, and liabilities amounting to \$250,993. The assets consist chiefly of two mines in St. Clair County, valued at \$100,000, according to the schedule. The company is 35 years old. Officials of the company said that bankruptcy was brought about by the fact that there is no market for coal. The company, they said, lost \$100,000 during the last year sustaining a \$3,000 monthly payroll loss during that time. They said it cost them \$1 to collect each 75c.

INDIANA

A real estate transaction involving the transfer of more than \$1,000,000 worth of property was completed in Chicago recently, when Alfred M. Ogle, president of the Vandalia Coal Co., and K. L. Ogle, both of Terre Haute, Ind., exchanged 3,800 acres of improved farm land near Linton, for a flat building containing seventy-two furnished apartments in Chicago. The apartment building, seven stories high, is located at Forty-fifth Street and Drexel Boulevard, only a short distance from the South Shore Country Club. The Ogle farms, which had been in the family for more than fifty years, consist of some of the finest farm land in the state, according to M. R. Mosher, of Indianapolis, the real estate dealer who represented the Ogle family in the transaction. About 2,000 acres are planted in corn.

Judge John E. Cox in Superior Court of Vigo County has granted a petition to Clem J. Richards, receiver for the Sugar Valley Coal Co., asking authority to the extent of \$20,000 to pay labor claims and meet other expenses of the company. Frank M. Steiner with a \$5,000 claim, was the creditor who petitioned the company into bankruptcy. The mine, which is located a half mile west of West Terre Haute, is said to have in the past furnished more wagon coal to Terre Haute than any other mine in the vicinity. It is not a wagon mine, however, but it located on the Vandalia R.R. and last year had an output of from five to six hundred tons per day.

With the closing down of the Keller mine No. 2 and Crown Hill Mine No. 7 a total of seven mines are now idle in the Clinton field, and 1,800 miners are out of employment. Lack of orders is said to be the cause of the dullness of the mines. Having lost the contract for supplying coal to the steel industry, the mines now are obliged to depend upon the open market. Operators contend that they lost the steel company contracts because the miners put out dirty coal. The miners, on the other

hand, hold that the contract was lost because the coal in this field is in competition with that of non-union fields, and that the Pennsylvania and other fields receive lower freight rates than the Clinton field.

The Hickory Grove Coal Mining Corporation, a New York corporation, has qualified to operate in Indiana with a capital of \$50,000 preferred and 500 shares common stock no par. Charles M. DuPuy of Riley, is their agent.

Farmers in southern Pike County have been granted an injunction against the Enos Coal Mining Co. from damming the dredge ditch of the south fork of the Patoka River constructed at a huge cost. The Enos Coal Company operates three big strip mines, owns thousands of acres of rich coal lands, and operates eight miles of railroad. With less than 3 ft. of water in its fifty-acre lake, the Enos Coal Co. recently petitioned the board of Pike County commissioners for the right to dam the bridge ditch, so as not to endanger its big mines from shutting down for the lack of water. The board of commissioners refused the petition. The coal company started to dam the ditch anyway. Then came the injunction.

IOWA

The Equality Coal Co. has established general offices in Albia. The company's mines are located north of Buxton. The business of the Gold Goose Coal Co. will be handled through the same office in Albia as that of the Equality. The Gold Goose company maintains its mines at Hamilton.

KENTUCKY

The Dixie Gem Consolidated Coal Co., of Middlesboro, capital \$10,000, has filed amended articles increasing capital to \$60,000.

With a capital of \$30,000, the S. W. W. Coal Co., of Pike County, at Sutton, has been chartered by Nora C. and A. C. Walther, of Sutton, and J. M. Smith, of Uniontown, Pa. The same interests formed the Rockledge Development Co., capital \$20,000.

The Clearfield Cannel Coal Co., of Morehead, in Rowan County, capital \$100,000, has been chartered by Guy Snyder and G. H. Gerheat, of Clearfield and Drew Evans, of Morehead.

MAINE

Bangor retail coal dealers have advanced the price of anthracite. The increase ranges from 75c. on stove, egg and nut coal to 25c. on pea coal. The price of bituminous coal remains without change at \$11.25 a ton. The new schedule of prices is as follows: Stove, egg and nut, \$17.00; pea, \$15.50; and steam \$11.25. The prices are all subject to a discount of 2 per cent for cash, which the leaders absorb together with a part of the advance at the mines.

MARYLAND

A bridge is being erected by the Consolidation Coal Co. across Georges Creek near Midland, Md., at the Ocean No. 1 mine in order to run loaded hoppers across the stream to connect with the Cumberland & Pennsylvania R.R.

A plant costing \$350,000 is to be built at Baltimore for briquetting anthracite dredged from the Susquehanna River. The first unit will have a capacity of 60,000 tons per year.

MASSACHUSETTS

The Joint Special Coal Investigating Committee has begun an investigation into the two recent increases in the retail price of anthracite, by publicly calling upon the leading retail dealers of metropolitan Boston to justify their position under oath. Fifteen dealers have been summoned to appear before the committee, with books, papers and other records pertinent to the

inquiry, in response to the committee's request. Emergency Fuel Administrator Eugene C. Hultman and Assistant Attorney General James H. Devlin aided the committee in conducting the hearing, which marked the first occasion in which the committee has used the full powers granted to it last May. Witnesses were warned that they were not being compelled to testify, so that they may not claim immunity in the event that proceedings are later instituted by the Attorney General or the District Attorney. Before swearing the witnesses Senator John W. Haigis, chairman of the committee, read a statement outlining the situation leading up to the price increases. The closing paragraph of the committee's statement caused a stir in the hearing room. It read: "The public does not ask charity. It is willing to pay a fair price. It is unwilling to be gouged. The two recent increases, aggregating \$1 a net ton, appear to be in part, at least, unwarranted. If they are not unwarranted, the public wants to know why. The purpose of this hearing is to get the facts. We want, and the public wants, the truth, the whole truth and nothing but the truth."

As a result of investigations by the office of the Emergency Fuel Administrator relative to the burning of fuel in home furnaces and heaters, E. C. Hultman, the administrator, has issued a brochure containing information on preparation of equipment, kinds of fuel, use of anthracite and bituminous coal, and the use of coke. Much advice is included on how to obtain the best results and least waste.

George Otis Smith, Director of the U. S. Geological Survey and who was a member of the United States Coal Commission, speaking on the coal industry and situation at a meeting of the Boston section, American Institute of Mining and Metallurgical Engineers, at the Engineer's Club, Boston, on Oct. 9, declared the coal industry to be the most wasteful in the world, both of capital and man power. "It is wasteful," he said, "from any possible angle of view, and even taking average figures we find extreme inefficiency and waste. The task of alleviating such conditions I lay not to labor or to capital, but to the engineers. It looks like their job to me. One good thing I have found is that, independent of the commission, and largely, I think, through fear of them, the industry has been investigating itself of late."

MICHIGAN

The Detroit Stoker Co. announces the appointment of E. L. Beckwith as district manager in charge of the company's Chicago office, address Illinois Merchants Bank Building. Mr. Beckwith is an engineer with many years experience in stoker sales work.

The Columbus (Ohio) office of the Pittsburgh Coal Co., announces that it will open a Detroit office about Nov. 1 with Arthur W. Marshall, who has been a salesman with the company for the past 18 years, as manager. For the past few years he had held the position of assistant sales manager. The Detroit office will be in the First National Bank Bldg.

A new coal mine is about to be sunk in Rush township near Owosso by the Copper Coal Mining Co., of Saginaw. Thirty inches of coal under a 300-acre tract is to be opened through a shaft 128 ft. deep.

MISSOURI

T. S. Clark, since 1903 connected with the Western Coal & Mining Co. of St. Louis and the Consolidated Coal Co., and for several years past auditor for the Western Coal & Mining Co., has resigned to accept a similar position with the Consolidated Coal Co. of St. Louis, succeeding F. L. Dubois, who died recently.

The coal mine in Elmira is to open again soon, according to reports from officials of the mine. The plant had been closed for more than a month because of a controversy between the operators and the miners.

MONTANA

George N. Griffin, State Coal Mine Inspector, reports that the mines in Montana produced 3,140,837 tons of coal in the year ended June 30, 1923. This does not include the output of a few small mines that did not report. The coal mined in the state had a value at the mine of \$9,903,625, the greatest of any year since 1901 with the exception of 1920, when \$10,393,908 worth of coal was produced. The coal industry gave employment in 1923 to 4,047 men, of whom 1,364 were miners who were em-

ployed on an average of 181 days for the year. Sixteen lives were lost in coal mining compared to only 7 the year previous. There were 196,302 tons of coal produced for each life lost. One person was killed for each 256 persons employed. The mines of the state used 78,399 kegs of powder and 49,339 lb. of dynamite. Fifty-four per cent of the coal was mined by hand, the remaining 46 per cent being mined by the use of machines, the latter giving employment to 169 miners. The inspector finds that "very few, if any, of the coal mines in the state have done anything in the way of first-aid work during the past year. It is to be regretted that operating companies do not take more interest in this matter, for it is the opinion of the writer that money expended along this line brings good returns." He states that in his opinion "if a part of the money paid out in the form of compensation was used in safety-first and first-aid work, the results would be very gratifying both from a monetary and humanitarian standpoint." Miners themselves do not take the interest in safety work that they should, the inspector states, and he calls attention to the fact that safety first-aid work means more to the employees than to the employers.

The King Coal Mining Co. has bought and begun operation of the Star mine of the old Star (Musselshell County) Mining Co. Abe Douglas is superintendent in charge of operations. The company expects to employ about 100 men at the property within the next 30 days.

NEW JERSEY

An involuntary petition in bankruptcy was filed on Oct. 9 in Federal Court at Newark, against the Irvington-Hilton Coal Co., of which the late Mayor Edward R. Folsom of Irvington was president. Louis Folsom, vice-president of the company and son of the late Mayor, filed a petition previously with Vice-Chancellor Foster asking that a receiver for the company be appointed. Vice-Chancellor Foster issued an order directing parties interested to show cause why a receiver should not be named. Federal Judge Runyon appointed Herbert W. Taylor as receiver of the company under \$5,000 bond upon application of Barney & Larkey, lawyers, for the creditors.

NEW YORK

Walter B. Johnson, heretofore with Whitney & Kemmerer for twenty-four years, is now associated with McCann-Camp Co., Inc., 90 West Street, New York.

The National Exposition of Power & Mechanical Engineering, to be held at the Grand Central Palace, New York, Dec. 3-8, is planned in co-operation with the national societies interested in the economy of fuel and in the production and use of power. The exposition will parallel the annual meeting of the American Society of Mechanical Engineers, which will be held at the Engineering Societies Building, 29 West 39th St., the first four days of the week. To avoid conflict between the two events, the sessions of interest to those who will attend the Power Exposition have been set for the mornings of the meeting and the exposition will not open until one o'clock each day. This parallel arrangement will give engineers the desired opportunity to enjoy both events to the greatest possible degree. Some of the subjects to be discussed at the annual meeting of the A. S. M. E. are: "Factors in the Spontaneous Combustion of Coal," by O. P. Hood; "Economic Phases of Coal Storage," by F. G. Tryon; "Coal Handling and Coal Storage," by H. E. Birch and H. V. Coes.

The Power Exposition offers an opportunity for the operating man to become acquainted with the latest devices in his field. This opportunity will be seized by the National Association of Stationary Engineers, the New York Building Owners and Managers Association, the New York Building Superintendents' Association, the Blue Room Engineering Society and the Ocean Associations of Marine Engineers, who will attend the exposition in groups. The office of the management of the exposition is in the Grand Central Palace.

The committee on coal of the Brooklyn Chamber of Commerce has under consideration a resolution recommending government ownership of coal. Prior to the introduction of the resolution Former United States Senator William M. Calder, who is chairman of the committee, reviewed the coal situation in Brooklyn and offered three suggestions in the search for a remedy. One of these was his old plan providing for a government agency with which coal companies and dealers would be compelled to file their price schedules, including costs and

profits. The second suggestion was to put coal under the supervision and control of the Interstate Commerce Commission and the third, which he said was "almost radical," was government ownership. J. Whitney Richardson who introduced the resolution said he did not approve of government ownership, but that it appeared the one thing which might awaken the coal operators to the situation they were creating for themselves.

Albert S. Fisher has been appointed manager for Pittsburgh Coal Co. at Buffalo, with offices in the Ellicott Square Building, succeeding Seymour Whitley, resigned. P. F. Ballou, formerly connected with the company's Erie (Pa.) office, has been transferred to the Buffalo office. The changes became effective Oct. 15.

More than 20,000 tons of coal stored in pockets of the East River Gas Co. Long Island City, were consumed on Oct. 13 in a fire which started in the coal bunkers. The origin of the fire is not known.

The Emerson-Morgan Coal Mining Corporation, New York City, has been incorporated to deal in coal, etc.; capital, 2,500 shares of no par value. Directors: George W. Hinckley, Produce Exchange Building, New York City; Eleanor Tempny and A. M. Menkel, New York City. Attorney, G. W. Hinckley.

Directors of the Norfolk & Western Ry. have declared an extra dividend of 1 per cent on the company's common stock in addition to the regular quarterly dividend of 1 1/2 per cent due to be declared at this time. Both dividends are payable Dec. 19 to stockholders of record Nov. 30. With the extra dividend the company pays 6 per cent on its common stock.

The Pennsylvania Coal & Coke Co. reports gross earnings of \$662,309 for September, compared with \$1,019,344 for the same month last year. Net income, before Federal taxes, amounted to 14,768, compared with \$321,891 for September, 1922. Gross earnings for the nine months ended September 30, last, were \$6,787,349, compared with \$2,648,264 for the same period last year. Net income, before Federal taxes, was \$741,962, compared with \$96,334 for the same period last year.

Charles P. Tolman, for sixteen years chief engineer and chairman of the Manufacturing Committee of the National Lead Co. and a past president of the National Safety Council, has resigned to open an office as consulting engineer at 111 Broadway, New York City. His specialties will be dust and fume control, handling materials and products and manufacturing methods and processes. He becomes consulting engineer for the National Lead Co.

The Walter Engineering Corporation, composed of Raymond A. Walter and associates, is opening an office at 299 Broadway, New York City, to make examinations and reports. Raymond A. Walter for the past year was one of the two engineers of the U. S. Coal Commission. With his associates Mr. Walter will make examinations and reports on coal mining, including financing, mergers, reorganization, consolidation, income tax, modern mechanical mining and every phase of development, operation, distribution and marketing.

OHIO

The Morrison & Risman Co., manufacturer of railway track equipment, Buffalo, N. Y., has established a district sales office in the Ulmer Building, Cleveland, in charge of R. B. Morrison. Warehouses also are being established in Cleveland, in addition to warehouse connections at Philadelphia, Buffalo and Lebanon. The company's Philadelphia office has been discontinued.

The Cincinnati Chamber of Commerce completed a "good will" trip by some 100 of its members through the southeastern Kentucky coal fields on Oct. 25, having been gone for five days and visited the more important coal mining centers of Hazard, Harlan and the Jenkins districts. Considerable publicity was given to the great areas of coal that were viewed by these commercial enthusiasts.

The Maher Iron Ore & Coal Co., New Lexington, has been chartered with an authorized capital of \$12,000 to deal in coal and mineral lands and to operate coal mines. Incorporators are C. A. Maher, James Maher, William A. Allen, O. H. Trout and George A. Forquer.

The Fennac Coal Co., Cleveland, has been chartered with a capital of \$10,000 to mine coal and to deal in coal and coke, both at wholesale and retail. Incorporators are M. W. Fennelley, W. C. Graves, C. W. McNamara, Clara E. McNamara and Anne Fennelley.

PENNSYLVANIA

Anthracite miners complain that the 10 per cent wage advance recently granted is having an indirect effect on the cost of living in some sections of the region. The men say that since they are getting the higher rate, landlords have been increasing their rents. Barbers of the Lehigh section have increased the price of haircuts and shaves. Haircuts now cost 50c. at most shops and shaves from 20 to 25c. Haircutting was done heretofore at 35c. and the charge for shaves was from 15 to 20c., depending on the class of trade.

Rinaldo Cappellini, president of District No. 1, United Mine Workers, last week announced that on Nov. 1 a compensation bureau, to investigate and contest for all mine workers of District No. 1 will be established. With this announcement, he also made public these appointments for the important work: Garfield Lewis, of Old Forge, compensation investigator, and Miss Helen Bolton, of Scranton, secretary. Mr. Cappellini explained that the secretary of the mine local union has been instructed to supply the district office at Scranton with a true and accurate account of every mine accident on the day it happens. These cases will be listed, and investigations made. Witnesses will be secured. Medical service will be granted, and when these cases are brought before the compensation referee either in Scranton or Wilkes-Barre, they will be properly prepared, and a fight made to win a fair and just award.

A second conference between Governor Pinchot and Samuel D. Warriner, chairman of the Anthracite Operators' Policy Committee, and other members of the committee, scheduled for Oct. 24, has been postponed. Mr. Warriner notified the Governor at Harrisburg that it would be impossible for some of the operators to get to Harrisburg because of board meetings. No date has been set for the meeting.

The Hazle-Brook Coal Co., of Hazleton plans to make Raven Run colliery, in the Schuylkill field, one of the largest operations in the anthracite district. Raven Run has been taken over from another leasing corporation. It is one of the few operations left in the hard-coal section that have virgin seams to be developed. A new steel and cement breaker is going up, houses are to be built for the miners and it is thought that within ten months the plant will be in full operation.

The Fayette-Greene Coal Producers Association will hold a dinner meeting at the Uniontown Country Club Thursday evening, Nov. 1. The meeting will be addressed by Charles O'Neil, secretary-treasurer of the Central Pennsylvania Coal Operators Association.

The Sessler Coal Co. has been organized at Uniontown by James T. Sessler and associates, capital, \$30,000.

The Kimberly Crest Coal Co. is a new corporation at Somerset; capital, \$50,000.

A contract for uncovering coal measures stretching from Oneida colliery to the Green Mountain line of the Lehigh & Wilkes-Barre Coal Co., five miles away, has been awarded by the Lehigh Valley Coal Co. The project will require two years for completion. Steam shovels will be used to take the clay off the anthracite outcrops and a network of temporary railroads will be built to haul away the debris to dumps beyond the coal measures. The coal taken out will be hauled 11 miles overground to the Jeannesville breaker for preparation for market.

The proposed merger of the Philadelphia & Reading Ry. and the Central Railroad of New Jersey with the New York Central R.R., which was given much consideration at the annual meeting of the State Chamber of Commerce at Harrisburg last week, is being studied by a special committee of the state organization appointed by Alba B. Johnson, president of the State Chamber. Opposition to the merger was voiced in a resolution sent to the Committee on Resolutions which in turn reported out a resolution favoring further study of the matter and the appointment of the committee. Speakers announced that the plan, if carried out, would result in much of the anthracite being taken to the Port of New York instead of Philadelphia and that other traffic would be diverted. President Johnson named the following committee, which will meet with him at Harrisburg, Nov. 6: E. J. Poole, chairman, Reading, sponsor of the original resolution condemning the merger; Jesse S. Bell, Williamsport; Harry C. Graham, Pittsburgh; John S. Rilling, Erie; Worthington Scranton, Scranton; Vernon F. Taylor, Indiana; John Uhl, Wilkes-Barre; Charles P. Vaughan, Philadelphia, and F. W. Walker, Beaver Falls.

The Straub-Atkinson Coal & Coke Co., Pittsburgh has changed its name to the Arch H. Straub Coal & Coke Co.

WEST VIRGINIA

The Cagney Coal & Coke Co., of Fairmont, has filed notice of incorporation in the offices of Secretary of State Houston G. Young; capital stock, \$25,000; incorporators, Harry Marshall, of South Brownsville, Pa.; J. W. Davis, of Hopwood, Pa.; D. F. Fries, of New York City; S. J. Titus, of Jefferson, Pa.; John A. Allen, of Smock, Pa.; A. C. Lee, of Masontown, Pa.; George H. Krepps, of East Millsboro, Pa.; Lloyd W. Cagney, of Point Marion, Pa., and E. J. Newcomer, of Uniontown, Pa.

New River coal lands will be developed by the **Cap Smokeless Fuel Co.**, which has just been chartered with a capitalization of \$75,000. The offices of the company for the present are to be at Charleston. Identified with the new company are William W. Burdette and Anis Burdette, of Handley; C. A. Purcell, M. P. Albertson and W. A. O'Neal, all of Charleston.

No. 2 mine of the Low Moor Co., at Fayette, which had been closed down for a short time, **has resumed operations.** Preparations are under way at the No. 1 mine of the same company to screen the output owing to the better demand for prepared sizes.

That coal lands in the Glenwood section of Ohio County are to be developed is indicated by the organization of **Wheeling-Glenwood Coal Co.**, with a capitalization of \$50,000. Offices of the company are at Wheeling. Incorporators of the new concern are E. L. Peters, V. H. Crites, Frank Hembert, Harry Long and V. B. Travis, all of Wheeling.

Men well known in the coal industry have taken out a charter for the **National Coal Inspection Bureau, Inc.**, with a capital stock of \$50,000. There has been a good deal of discussion of such an organization in the trade recently, its purpose being to insure the shipping of coal of better quality and to put a stop to the rejection of coal of quality, all through a system of inspection much like that utilized in the lumber industry. Incorporators of the Bureau are Justus Collins, president of the Smokeless Fuel Co., Charleston; O. J. Cox president of the Kanawha Valley Coal Co., Charleston; L. B. Ramsey, of the Logan Fuel Co., Charleston; H. P. Elliott, general manager of the Stange-Elliott Coal Co., of Charleston, and W. D. Roberts, of the **National Coal Mining News**, Charleston.

Organization of the Jaunda Mining Co., with a capital stock of \$130,000, presages further development of coal lands in the Kanawha County field. The company will have its office at Charleston. Identified with the new enterprise are J. W. Keeney, of Eskdale; C. W. Estep, H. A. Stewart, Milton Crites and L. Jaffe, all of Charleston.

Work has been completed by the **West Virginia Coal & Coke Co.**, on its new store building and also on its new office building at Norton, in the Elkins field. The total cost of the two structures is about \$40,000. The company will also erect a new and modern tippie at its Junior plant when conditions justify it, to replace the one destroyed by fire.

The Pinnacle Coal & Coke Co., of Spring Forks, has been authorized to increase its capital stock from \$500,000 to \$750,000.

Operations in Pocahontas territory will be undertaken by the **Royal Pocahontas Coal Co.**, which has just been organized with a capital stock of \$20,000. This company will operate in the vicinity of Jaeger, which will be the headquarters of the company. Having an active part in organizing the new company were T. B. Lane and Carmie G. Lane, of Jaeger; H. H. Liegett, A. F. Meyer and Marguerite L. Marsh, of Cincinnati, Ohio.

WISCONSIN

Senator Irvine Lenroot, speaking at Marshfield on Oct. 12 announced he will **support governmental regulation of the anthracite industry** and control of coal prices that the public may be protected against profiteering, as recommended by the Commission created by the last Congress. Following closely the findings of the Commission, the Senator said there should be little or no increase in the price of anthracite by reason of the recent advance in wages, "for a reduction of the net profits of the operators to a reasonable basis will absorb nearly all of the increase in wages." Since the anthracite industry has been found to be an excessive profit-making monopoly it is proper that it should be brought within by the government, he pointed out.

WYOMING

The U. S. Land Office at Evanston, has been directed to offer for lease a tract of **480 acres of public land** in Unta County, 14

miles south of Kemmerer and about 1½ miles east of Cumberland, on the Cumberland branch of the Wyoming Western R.R., **containing several thick beds of high-grade bituminous coal.** Lease for this tract will be at a government royalty of 10c. per ton for coal mined, a minimum investment in mining operations of \$75,000 during the first three years and a minimum production of 45,000 tons of coal a year beginning with the fourth year.

WASHINGTON, D. C.

Senator Oddie, of Nevada, has practically completed preparation of a bill creating a **Department of Mines**, whose head shall be a Secretary of Mines with a seat in the President's Cabinet. The Senator plans to submit the proposed bill to mining interests for analysis before its introduction when Congress convenes in order to obtain the advice and suggestions of those interested in the mining industry, as well as of government departments and bureaus to be affected thereby.

Walter D. Rogers has joined the National Retail Coal Merchants' Association as assistant secretary. He was with the U. S. Coal Commission and is one of the authors of the Commission's report covering the retail trade. He had charge of the Commission's investigation in Boston, Mass., last

WALTER D. ROGERS

winter and also made special cost studies for it in New York City and Washington, D. C. His experience as a Congressional secretary in Washington and his experience in New York City as an auditor and credit manager should make him a strong man for the association. Mr. Rogers served two years in the United States Army during the war, and for a year afterward was with the American Red Cross.

That research on mining problems be coordinated and that new work be undertaken on a co-operative basis has been proposed by the British government, and the plan has been approved by the American State Department. The Department of the Interior has been authorized to proceed directly by the British Board of Trade in the perfecting of the arrangement. The action of the British Government is an outgrowth of the recent visit to that country of George S. Rice, chief engineer of the U. S. Bureau of Mines. While in England Mr. Rice had frequent opportunity to point out the character and scope of the research being conducted in this country. British mining engineers were impressed with the fact that the research in that country was along almost identical lines. The arrangement is being entered into with the idea of avoiding duplication and making possible a greatly enlarged program. Mr. Rice was elected an honorary member of the British Institution of Mining Engineers. Lord Curzon, the Foreign Minister, has formally conveyed to the State Department the thanks of the British Government for the constructive suggestions and advice conveyed by Mr. Rice during his visit.

The U. S. Supreme Court on Oct. 22 denied a writ of certiorari sought by the **Sandford Coal Co.** of Illinois to review a decision of the lower courts awarding a judgment of \$41,409, including interest, to the Wisconsin Bridge & Iron Co. for a tippie at a mine in Williamson County, Ill. The judgment therefore stands. The coal company did not deny ordering the tippie, but in the suit set up a counter claim for damages on the ground that it had suffered losses due to delay in installing the tippie.

This claim the lower courts refused to entertain in the suit at issue. The tippie was ordered in November, 1919, to be completed July 1, 1920. In the meantime the development of the mine proceeded with a temporary wooden tippie of limited capacity. The steel tippie was not completed, the coal company alleged, until in December, 1920, although it was put into use in October previous. Because of this delay, the coal company alleged it had lost business as its output was restricted to 150 tons daily whereas with proper tippie equipment it could have raised, and sold, 760 tons daily.

The Federated American Engineering Societies announced that **Arthur P. Davis**, whose recent dismissal as Director of the U. S. Reclamation Service by Secretary of Interior Work caused a nationwide protest by engineers, **has been retained by the State Department as technical adviser** in connection with certain claims against the United States by British citizens which are to be tried before the Pecuniary Claims Arbitration Commission in London beginning Nov. 6. The arbitration of these claims was provided for by a special law of Congress to clear the docket of old pending claims which have not been settled. Mr. Davis sailed for England Oct. 23 to assist in the preparation of these cases prior to their consideration.

CANADA

The coal miners of Nova Scotia have requested the management of the Dominion Coal Co. to set a date at which a new wage contract will be discussed. Union officials have for some years been endeavoring to change the date for the termination of contracts from December to April, at which time all contracts in the American and Western Canadian coal fields terminate, but so far have not been successful.

F. A. Coombe, a Montreal steam and combustion engineer, chairman of the Fuel Committee of the Engineering Institute of Canada, has been engaged to make an **exhaustive report on the feasibility of establishing central heating plants in Canada.** The investigation will be conducted under the supervision of the Dominion Fuel Board, and the report must be completed within six months. Particular attention will be given to the saving that can be effected by the use of low-grade fuel in these plants.

The Dominion Coal Co. will spend \$2,000,000 in opening up a new mine at Lingan, construction of a branch railway to the site having been started. The new colliery will be equipped with the most modern devices. It will tap the Phelan seam and have a capacity of 2,000 tons daily.

J. B. MacLachlan, deposed district secretary of the United Mine Workers of America, was convicted at Halifax, Oct. 17 of **sedition and spreading false tales.** Throughout the trial MacLachlan maintained a confident air and the worst he looked for, apparently, was disagreement by the jury. At the conclusion of the hearing he was taken back to jail to remain until the last day of the month, when sentence was to be pronounced. The general feeling is that the verdict is a just one and that the prisoner could expect nothing else from an unbiased jury. It may be that counsel for MacLachlan will appeal the verdict, but it is questioned if a better decision could be had from the full bench. The trial of Dan Livingston, former district president of the U. M. W., has been postponed until the next sitting of the Supreme Court. He will be given hearing on similar charges to those on which MacLachlan was convicted.

JAPAN

A letter just received by H. Foster Bain, director of the Bureau of Mines, tells of the escape from injury of several prominent Japanese engineers who were in Tokio at the time of the earthquake, among them **Dr. Takuma Dan**, who is well known in this country. He was educated at the Massachusetts Institute of Technology and is one of the partners in Mitsui & Co. He developed the Manda coal mine in southern Japan. In the development of this mine the most modern mechanical equipment has been used. Owing to the large amount of water which had to be handled, Dr. Dan designed special pumps for it. When the designs were received by the pump manufacturers, they held up work on the order until they could cable to make sure that the decimal points were in the right places. As the pumps were the largest ever manufactured at that time, the manufacturers feared that someone had slipped a decimal point. Incidentally these pumps, after many years, still are being operated satisfactorily.

Obituary

John A. Clark, one of the best known coal operators of northern West Virginia, died Oct. 19 at his home at Fairmont, W. Va., after an illness covering a period of several years. Mr. Clark was born at Cumberland, Md., in 1855. After considerable experience he became an independent coal operator on April 1, 1891, when he organized the Clark Coal & Coke Co. with a mine at Pritchard on the Monongahela River Railway. Later he opened a mine at Anderson and a mine at Chiefton. He purchased the mine of the Pitcairn Coal Co. in 1910 and organized the Harry B. Coal & Coke Co., making his three sons his associates, Mr. Clark becoming the president of the company. A few years later he organized the Car-Diff Smokeless Coal Co. and the Dixie Mining Co., these companies being operated as separate concerns until the organization of the Clark Coal & Coke Co., in February, 1922. About 1899 Mr. Clark organized the Columbia Coal & Coke Co., at Columbia, and the Fairmont & Baltimore Coal & Coke Co., at Adamston, those companies later being purchased by the Fairmont Coal Co., now the Consolidation Coal Co. In 1901 the Waldo mine at Wilsonburg was opened as was the Goff mine, the New Chiefton and the New Randolph, which were operated as properties of the Madeira Hill-Clark Coal Co. Funeral services were held at the family residence at Fairmont, Oct. 21, burial being at Woodlawn Cemetery. His wife and three sons survive.

P. W. (Pat) Wickham, general superintendent of the mine properties of the New York Coal Co. in the Hocking field, died at Nelsonville, Ohio, Oct. 17, after a brief illness. He was 48 years old.

General James Lewis Caldwell, one of the pioneer figures in the development of the coal resources of southern West Virginia, died Oct. 18. General Caldwell, who was a veteran of the Civil War, president of the First National Bank of Huntington and head of the Dingress Run Coal Co., with extensive holdings in Logan County, succumbed to an illness covering a period of eight months resulting from an attack of influenza. General Caldwell was born at Elizabeth, in Wirt County, W. Va., on May 20, 1846. In 1862 he joined the Union forces and served until the end of the war. A few years after organizing the First National Bank of Huntington, of which he was president for almost forty years, Mr. Caldwell built the Guvandotte Ry., which is now a part of the C. & O. system, that road leading to the Logan field, where Mr. Caldwell acquired much coal acreage. The Dingress Run Coal Co., of which he was the president at the time of his death, is said to own 30,000 acres of coal land in Logan County on which twenty mines are operating. He also was secretary and treasurer of the Logan Cannel Coal Co. at the time of his death. Funeral services were held at the First Presbyterian Church of Huntington Oct. 20. The widow and six children survive.

Jake Brady, president of the Brady-Tucker Coal Co. died Oct. 22, following an operation for appendicitis at Christ Hospital. Mr. Brady was reared in the coal business, his father having been associated with several retail and wholesale companies of Cincinnati. He started with Kewett, Bigelow & Brooks as a lad of twenty and worked himself upward until his appointment as general manager of sales some fifteen months ago. After a re-arrangement of the selling department of that company Mr. Brady formed the Brady-Tucker Coal Co. with Larry Tucker, who had been with the Central Fuel Co., and his firm prospered despite the hard times that have beset the trade in the last year. He had been ill only a few days when the end came. He was thirty years of age.

Trade Literature

Welding and Cutting Equipment. Torch-welding Equipment Co., Chicago, Ill. Catalog 23. Pp. 40; 8x11 in.; illustrated. Cross-sectional views with detailed explanation of oxyacetylene welding and cutting apparatus, lead welding, soldering, brazing and decarbonizing units, gas-pressure regulators, automatic machines, generators and supplies are included.

Bethlehem Steel Co., Bethlehem, Pa., has issued an interesting little book, Publication No. 26, describing the nature and uses of **Mayari Pig Iron**. Some useful data compiled especially for the book by Dr. Richard Moldenke are included. Price, \$2.00.

Motorbloc — The Motor-Driven Hoist. Motorbloc Corp., Summerdale, Philadelphia, Pa. Bulletin S-101. A 6-page folder describing and illustrating the lightness and portability of the device.

Publications Received

Erection of Barricades During Mine Fires or After Explosions, by J. W. Paul, B. O. Pickard and M. W. von Bernewitz, Bureau of Mines, Washington, D. C. Miners' Circular 25. Pp. 27; 6x9 in.; illustrated. Contains short description of some of the gases found in mines, tells what to do at time of fire or explosion, with practical recommendations, and gives life-sustaining capacity of barricaded chambers. Experiences of erection of barricades at mines during explosions are included.

The Morse Chain Co., Ithaca, N. Y. has issued in book form the address by F. L. Morse at the 26th annual convention of the American Mining Congress on **"Power, Its Application from the 17th Dynasty to the 20th Century."** The book has 46pp., is 6x9 in. and well illustrated.

Analyses of Illinois Coals, by G. W. Hawley, Illinois Mining Investigations, Urbana, Ill.; prepared under a co-operative agreement between the Illinois State Geological Survey Division, the Engineering Experiment Station of the University of Illinois and the U. S. Bureau of Mines. Co-operative Mining Series. Extract A from Bulletin No. 27. Pp. 68; 6x9 in.; tables.

Traffic News

Rates on coal from Winton, Wyo., to destinations in various Western states have been found by the Interstate Commerce Commission to be unreasonable to the extent that they exceed the rates in effect at the time from the Rock Springs-Kemmerer group in which Winton was subsequently included. As a result of that decision, reparation has been awarded covering shipments made by the Megeath Coal Co.

The Interstate Commerce Commission will hold its **hearings into anthracite freight rates from Pennsylvania to Canada, New York and other northeastern states at Albany, N. Y., Nov. 5**, according to an announcement Oct. 17 by the New York Public Service Commission.

The Southern Appalachian Coal Operators' Association was **unsuccessful in its efforts to establish that freight rates charged from mines in its territory to Louisville, Ky., are unreasonable and preferential to competing coal operators in western Kentucky.** The Interstate Commission, in a formal opinion handed down Oct. 26, holds that the rates are not unreasonable or unduly prejudicial. The Commission pointed out that if the rates from western Kentucky to Louisville were increased, it would not benefit the Southern Appalachian operators but simply would give a greater advantage to mines served by the Illinois Central. The Commission points to the statement that Illinois mines are capable of increasing their tonnage intended for Louisville sufficiently to displace all coal now shipped to that city from mines on the Louisville & Nashville. The Commission also made the point that shipments to Louisville from Southern Appalachian territory are increasing, whereas those from western Kentucky mines are decreasing.

Hereafter, according to announcement just made, the **Norfolk & Western Ry. will accept privately owned cars as "assigned" or privately owned equipment.** Heretofore the N. & W. has steadfastly refused to handle privately owned cars as other than the general run of cars and has so allotted and distributed such equipment. In some quarters it is expected that the mining companies controlled by Henry Ford will take advantage of this opportunity to use D. T. & I. equipment. It is certain that more companies would have taken advantage of the new ruling if it had been made a year ago, when the spot market was stronger.

Hearing into the complaint filed by coastwise steamship and towing companies that charges for dumping, trimming and other port services at the three coal terminals at Hampton Roads are unreasonable and unjust were in progress at Norfolk all last week, before Examiner W. A. Disque, of the Interstate Commerce Com-

mission. The complaint was filed in April by the Coastwise Transportation Corporation, of Boston; the Southern Transportation Co., of Philadelphia; the Eastern Transportation Co., of Baltimore; the Staples Transportation Co., of New York; the Neptune Line, Inc., of New York, and the Thames Towing Co., of New London, Conn. Defendants in the hearing are the Norfolk & Western Ry., the Virginian Ry., the Chesapeake & Ohio Ry., the Lines Co., the Lamberts Point Towboat Co., and F. R. Barrett, stevedore. Witnesses for the complainants introduced testimony in efforts to substantiate the charge that the costs to the steamers and tows handling transhipped coal for New England were too high. Comparisons were made with the same services performed at Baltimore and Philadelphia to show that it was relatively higher at Hampton Roads than at those two competitive ports. Examiner Disque will report on the testimony taken and the decision is not expected for several months.

Coal rates to a large number of Indiana towns have been attacked by the Community Traffic Service Bureau, of Anderson, Ind. The Bureau claims that points east of Indianapolis and south of the line of the Big Four from Indianapolis to Union City, inclusively, have been paying a higher rate than is warranted. The destinations involved are located similarly to Indianapolis as far as service on West Virginia and Kentucky coal is concerned, it is claimed. Similar claims are being made as to rates on the Chicago, Indianapolis & Louisville north of Indianapolis as far as Monticello and to certain points on the Pennsylvania and Big Four west of Indianapolis. It is declared that certain points receiving switching service from Indianapolis yards have been compelled to pay the Chicago rate on coal, despite the fact that the latter point is 200 miles further away with a difference in rate over Indianapolis of 63c. a ton. It is stated that the rates from the Illinois fields and other territory into Indiana have been on a very much lower basis than the rates complained of. The whole situation is said to grow out of the zoning system put into effect by the Fuel Administration during the war. There are other special features involved, including alleged violations of the third and fourth sections of the act to regulate commerce.

The railroads on Oct. 17 moved more freight cars, both loaded and empty than ever before on any one day in history, according to a report by the American Railway Association. Fifty-two Class 1 railroads, representing about 90 per cent of the mileage for that class of carriers, on that day moved 1,029,428 cars. Between May 19 and Oct. 13, inclusive, the latest figures available, more than one million cars have been loaded with revenue freight in seventeen different weeks. In thirteen of those weeks the record loading which was made during the week of October 14, 1920, when the total was 1,018,539 and which stood until this year, has been exceeded. The present record loading of 1,097,274 cars was made during the week of Sept. 29 this year.

It is generally understood in coal circles in southern West Virginia that **D. H. Maher, president of the Norfolk & Western, will retire as such on Jan. 1, 1924**, having reached the age limit. Mr. Maher has been connected with Norfolk & Western for many years and ranks high as an executive. There is a good deal of speculation as to who will succeed the retiring president, in the event that he retires.

Reports just filed by railroads show that **only 151,332 freight cars out of a total number owned of about 2,300,000 were in need of repair on Oct. 1** this year, or 6.7 per cent. This compares with 216,011, or 9.4 per cent on Jan. 1. The railroads on Oct. 1 also had only 9,823 locomotives, or 15.3 per cent of the number on line, in need of repair. On Jan. 1 this year, 15,549, or 24.1 per cent, were in need of repair.

Coming Meetings

Harlan County Coal Operators' Association, Nov. 21, Harlan, Ky. Secretary, E. R. Clayton, Harlan, Ky.

Second National Exposition of Power & Mechanical Engineering, Grand Central Palace, New York City, Dec. 3-8. Managers, C. F. Roth and F. W. Payne, Grand Central Palace, New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 24

NEW YORK, NOVEMBER 8, 1923

Number 19

Time to Clean House

THERE is a deal of difference between prices for coal set by the ordinary play of supply and demand and prices set by force. Most of the complaints about the high prices for coal in the past few years have had no other justification than that buyers, wanting coal faster than it could be supplied, bid up the price. Abnormal conditions accentuated the normal result of effect following cause. The operator increased his price with the market and the increase was passed on. But there is today an unnatural factor introduced into the trade in the East that brings no credit to those who resort to its exercise.

Bituminous coal is being sold with a club. And that club is putting an unwarranted premium on anthracite while cutting the heart out of the soft-coal market. Dealers are being forced to take bituminous coal or steam sizes of anthracite, often car for car, with deliveries of domestic sizes of hard coal. Of course the tonnage of anthracite that is thus marketed is small compared with the whole, but the effect on the trade is important and on prices is entirely out of proportion to the volume of business so done.

The dealers have little or no market for or ability to sell this steam coal, whether hard or soft, and they turn it back on the market, to be sold at any price that it will bring, thus depressing the spot price of steam coal. Their losses are made up by putting a premium on the egg, stove and nut anthracite they get. The soft-coal house, whether producer or wholesaler, that is lending itself to this practice is hurting its own business and adding to the discredit of the whole industry. At best but a very small fraction of the bituminous coal seeking a market can be forced on the trade in this fashion, and when as a direct result of the distress in which it finds itself some of that coal is publicly offered at a dollar a ton, the buyers are given an entirely erroneous idea of values.

But however complacent the buyer of steam coal may be as the coal man undermines his own prices, the buyer of hard coal has just cause for complaint. The present high price of independent anthracite is not warranted. Neither the production and deliveries to date this year nor the weather can be used to explain \$11 and \$12 hard coal to the dealer. "Backdoor" trading has always been a feature of the New York market. It is not an indictable offense, nor is it less outside the letter of the law when a seller dribbles out a portion of his product through a willing free-lance jobber to be sold at a price higher than he is willing openly to quote it.

Not only are ordinary good business ethics violated by such pandering to the desire for immediate large profit but the whole scheme is unsound merchandising. The trade knows these things, it knows who are the prime movers and pace setters, and who of good reputation have fallen. It is no cause for self congratulation that

the District Attorney and the Federal Trade Commission can "get nothing on them." The argument that it is fair to charge the "market" and unfair to suggest or to expect one to sell for less falls down when the buyer is blackjacked.

Misrepresentative Statistics

IT DOES not subtract from the distrust in which all coal men hold the Federal Trade Commission when that body resorts to such unfair tactics as are challenged by E. W. Parker in an open letter to Chairman Murdock. The Trade Commission is rendering the public—at the request of the President—current reports on anthracite showing the movement through jobbers and the commissions charged.

Mr. Parker is exposing a statistical trick used by the Trade Commission to conceal the meagerness of its returns, and, whether intentional or not, a trick that misrepresents the facts. The objection is to the use of percentages without showing the quantities or the relationship to the whole output, as when the last report of the Trade Commission said that one-third of the tonnage of anthracite was sold at more than \$12 per ton at the mine—an obviously incorrect statement with respect to the industry as a whole, but doubtless true of the sales on which the report was based, which may have represented but 1 or 2 per cent of the total business.

Taking Up Coal in a "Serious" Way

MRS. LOUIS REED WELZMILLER, Deputy Commissioner of Public Markets of New York City, is the economical, efficient kind of citizen that should be put in charge of all public work. For a small sum to cover a few days' expenses in the anthracite fields, she has given us a report on hard coal that for conciseness, definiteness, positiveness, and assertiveness puts to shame everything previously attempted.

Mrs. Welzmillier has "done" coal before. She investigated Somerset County during the 1922 strike and had her picture in the Hirshfield report to Mayor Hylan. It is surprising how much one with that experience was able to accomplish in investigating anthracite. What a waste the \$600,000 spent by the Coal Commission! And the time saved, too! And against such odds! Why the horrid coal companies refused to let her underground to see how much coal is left, but she overcame that hazard by disguising herself as a miner and with the assistance of a hardy union official stole past the minion at the portal—or should we say the cager?

How simple it all is, if one but has an open mind, a few days and sufficient disguise! Mrs. Welzmillier drew seven numbered conclusions that may easily be stated as follows: There is more anthracite than the public knows about and there are new deposits yet to be

found; the price is too high and freight rates must come down; the miners are not overpaid; and the industry should be regulated by Washington and the department of public markets for which Mrs. Welzmillier works.

Perhaps one should be more charitable toward the Coal Commission for not being so decisive.

Substitutes for Unions

LABOR federationists have again attacked the Mitten employee-representation and co-operative profit-sharing plan of the Philadelphia Rapid Transit Co. Mr. Mahon, president of the union of street railway employees, assailed it at a recent convention of this union as absolutely hostile to trade-union collective bargaining, adding that it seeks to destroy trade unionism itself.

The basis of the attack on what Mr. Mahon has dubbed "Mittenism" is that by providing a workable substitute for unionism, that form of collective bargaining has been superseded and is in effect displaced. What has been provided is a working arrangement that inspires the worker as well as the management to better service because they are all partners in the business. There is no place here for the three words that adorn the banner of the A. F. of L.—"Agitate! Educate! Organize!"

There need be no great fear that the Mitten plan is going to put the unions out of business at once. The employers require almost as much education in industrial relations as do the employees before that can come to pass.

Business Indicators and Coal Stocks

THE energetic coal man has already discounted this winter's business and is talking about the prospects for next season. With only the normal seasonal demand for household coal in sight, with the unusually heavy Lake movement soon to be cut off, and with steam-coal buyers heavily stocked there is no prospect of a market recovery. A heavy volume of steam coal is moving on contracts but it requires pressure to sell spot coal. The least tendency toward an upward turn in quotations would now cause buyers to withdraw and wait, leaning on their stockpiles.

Were it not for the uncertainty of what will happen next spring—the strike threat—there would be a slackening in demand and production of bituminous coal even this early in the winter. The coal buyer is more fearful of a strike next April than is the coal producer. This feeling on his part has prompted in large measure the steady buying of steam coal this autumn. The only thing that will dispel the feeling is a new contract, signed, sealed and delivered. Industry weathered the 1922 coal and railroad strikes and prospered because of heavy stocks. The lesson has not been forgotten.

It is a long shot to look into next year, but there are a few factors now apparent that will affect next summer's coal history. Production of goods into the manufacture of which coal enters in quantity is quite generally on a declining rate. Pig iron, steel, textiles, paper, flour, and packing-house products, all heavy coal users, are below the level of activity of the midyear. The textiles, indeed, are less active than at this period last year.

Notwithstanding this evidence of slowness, November

opened with the business world optimistic, the stock market after months of dullness spurting upward, everywhere confidence in good business this winter. The better business is this winter, the more avid the industrial consumer and railroads will be in holding to and even increasing coal stocks against next April. The size of that stockpile next March will be the biggest argument to be faced when a strike is being considered, and it will likewise, in the event of no strike, be the largest single factor in setting the level of coal prices for the next coal year.

Who Will Read Them?

FROM time to time wonderment has been expressed at the volume of the reports issued by the U. S. Coal Commission and gloomy prediction made that the public would never know their contents. The coal industry has a heavy investment in these reports and wants the people to know more about coal. Interest on the outside is such that former strangers to coal are interpreting the Coal Commission's findings to large sections of the public.

An instance in point is the publication in the Northwest of a series of specially written articles on coal in *The Farmer*, which claims to reach 130,000 farmers in that region. Two articles dealt with anthracite, the third with bituminous coal. The writer of the series gave a fair interpretation in popular language of what the Coal Commission had published up to the time the articles were written.

The farmer will learn from the articles that the full-time worker in hard coal gets from \$2,700 to \$3,200 per year and the great majority of the men between \$1,700 and \$2,000 a year. He is told that the miners had a weak case this year and the "public is not likely to have much patience with it." The hard-coal operators are charged with having a large part also in the high price the farmer of the Northwest pays for his anthracite. The monopoly sections of the Coal Commission's report are quoted.

The writer of these articles for *The Farmer* closes that on anthracite with a little punch of his own as follows:

What is needed most, however, is a little real temper on the part of the long-suffering and too patient public. What is needed is an insistent public demand that legislation to regulate profits and to curb the arrogant dictatorship of union mine labor shall be passed. What is needed is a little more knowledge that anthracite is not the only kind of coal, a little more co-operation in buying during the summer season, and a whole lot of independence in seeking and using substitutes, such as soft coal and oil.

When the public gets busy, and only then, our domestic fuel problem will be solved. And there is a widespread suspicion that the public is going to get so busy this coming winter that Congress will be forced to legislate some of the excess profits and needless shortages out of the anthracite industry, and legislate into it some decent business practices and some respect for the public interest.

The article on bituminous coal is a liberal interpretation of the Coal Commission's ideas and theories. It is summed up with the assertion that the only remedy for the major ills of the coal industry is government regulation, but if not, "then the only alternative is government operation, and the people of this country are not in favor of that."

Thus does John Brown's Body Go Marching On.

Coal Commission Suggests

Ways of Operating Mines That Would Lower Cost

Machine Loading Has Been Proved Efficient—Introduced in Half of Our Coal Mines It Would Save \$200,000,000 a Year—Concentration of Output Would Make Supervision Easier and More Effectual

IN every industry certain organizations have surpassed others in the skill and initiative in which they have handled their management problems. The development of science in industry, moreover, has proved conclusively that certain general principles of management—principles recognized as fundamental only within the last few years—are of universal application in all industries. It is thus evident that it is practical and worth while to examine underground mine conditions both on the basis of the best managed mines and also in the light of the developments that have taken place in industry as a whole during the last fifteen years.

The vital relation of such developments to harmonious labor relations lies in the elimination of causes of friction and the substitution of facts for opinions.

Strictly confining ourselves in this study to underground management, features of vital importance to the future of bituminous coal mining are:

(1) Development of machinery to replace the irksome and solitary operation of hand loading. In this lies the greatest opportunity, not only for lowering costs but for the improvement of mining conditions and the reduction of accidents. The importance of this can be realized when it is appreciated that with the introduction of machine loading and the incidental developments accompanying installation of machines, the total cost of coal at the mine in many cases may be reduced by

THE FOLLOWING is a reproduction of the document with which the National Coal Commission submitted the report on "Underground Management in Bituminous Mines" to the President:

To the President and the Congress of the United States:

As a result of its engineering study on Underground Management in Bituminous Mines, the U. S. Coal Commission believes that reductions can be made in the cost of production through improvement of operating methods, without any reduction in wage rates, by the:

Development and efficient application of mechanical devices to replace hand loading;

Better control and co-ordination of underground operations, particularly cutting, loading, and haulage;

Standardization and co-ordination of the work of the individual mine worker;

Standardization of details of construction and dimensions of mine cars, locomotives, track and all other equipment; and

Multiple shifting of work in the mines and preparation plants, thus obtaining greater production with the same plant investment.

The detailed report on Underground Management in Bituminous Mines follows. It was prepared by Stanford E. Thompson, of the Thompson & Lightner Co., of Boston, in consultation with Howard N. Eavenson, and assisted by George T. Haldeman, under the direction of C. E. Leshner and Raymond A. Walter, engineers of the Commission.

as much as 30 per cent of the present costs. This may be shown by actual operating results. Assuming such reduction possible in only one-half of the bituminous mines the actual net saving in money value would amount to over \$200,000,000 per year.

(2) Control of underground operations. Both in machine- and hand-loading mines progress must be toward functional methods of planning and control of the work of the men and machines, such as have been introduced in industries other than coal mining. Instead of leaving the distribution of miners' cars to the motorman or assistant foreman, instead of a hit-or-miss supervision of cutting machines and of company men, more definite planning and control of transportation and of all other underground operations is needed. This must include not merely a morning schedule, such as is now thought out in some mines, but a positive control continued throughout the day to include not only the directing of the mine cars to the miner and the regulation of locomotive trips but also the correlating of the operation of cutting machines and all the company work with coal loading. Increase in output at the mines will naturally follow such developments and also afford a saving in overhead and a gradual cost reduction with increased contentment of the workers through the elimination of lost time.

(3) Improvement in the work of the individual. Analyses of the operations and a determination of the

best methods and times for accomplishment will result in larger performance by company men, will provide a basis for the more thorough co-ordination of the work, reduction of delays, systematic handling of dead work, development of standards of production for company men as well as loaders, and eventually balanced earnings, not from the standpoint of uniform wages and piece rates as at present, but such as will give each man a square deal and a reward for his individual performance.

(4) Standardization of equipment, such as mine cars, motors, weight and gage of track, electrical equipment, etc., with determination of the best for each individual mine.

The foregoing features in this study omit consideration of the effect of railroad-car supply and excess mines on operating problems as these are treated elsewhere in the report of the Commission, but it may be said here that where more than one shift has been found practicable, an appreciable saving and a reduction in overhead expense has been attained.

MANAGEMENT MAKES—OR BREAKS—MINES

The effect of improved underground management on the miners is strikingly illustrated by a comparison of two mines thirty miles apart, in the same district, extracting the same seam, having similar physical conditions and afforded a similar railroad-car supply, both being union mines. In the one, plenty of miners are available at all times; in the other, such a scarcity prevails that the mine is running only at part production. The difference lies in the methods of managing the underground operations, the distribution of mine cars, the co-ordination of cutting machines, the handling of dead work, the supervision of company men. And yet the handling of the better-managed mine, and in fact even of the larger and better-equipped mines throughout the various fields, is found, at least in underground methods, to be generally behind that in some of the other major lines of industry.

So greatly do conditions vary in different mines with respect to the thickness and character of the seam, the quantity and nature of the slate, the condition of the roof and floor, the drainage, ventilation, etc., that no two mines are alike and many important differences in operating details are necessary. After giving due consideration to the breadth of the territory embraced by the industry and the different physical difficulties encountered, it appears, however, that the general scheme of handling work underground is quite uniform, perhaps even remarkably so, and as uniform, in fact as that in many other large industries, although the opinion of many mining men is to the contrary. Because of this basic uniformity it seems possible through a careful analysis of a comparatively few mines located in representative states and districts, and a broad general survey of the field, supplemented by the studies of other Commission investigators, to present specific conclusions and recommendations.

In the studies at the mines the field parties have received the cordial co-operation of the representatives of the operators and of miners, who exhibited evident appreciation of the constructive possibilities of a better management of mining operations.

The contentment of the miner during his working hours and the regularity of his remuneration while the mine is operating depend upon the underground management. With the advent of electric haulage, electric

lights, ventilation and safety appliances, management methods more and more are being recognized as properly controlling, in a measure formerly considered impossible, the effect of varying physical conditions in the mines.

The profits of the operator, also, to a larger extent than is generally recognized, are dependent upon his management of the mine. Assuming, for example, a 15c. profit per ton; if he can reduce his cost of mining only 5c. per ton, with the same selling price, he automatically increases his profit one-third. The consumer benefits as soon as such cost reductions become general, or even before, as the seller reduces his prices in competition.

This designation of management as a major feature is made with full appreciation of the vital importance to the industry of the railroad car supply, the number of mines, and the storage of coal. In fact, all these inevitably affect the management in the mine, because of the direct effect of each of them on the working time of the miner and the cost to the operator. However, except as these indirectly affect the management of the mine, their consideration is left to other divisions of the Commission's report, and we take up here the means for cost reduction and for improving the miner's physical and financial condition through the treatment of the management problems at the mine.

Strange as it may seem to those acquainted with the industrial developments in factory management during the last decade, though the initial layout and development and equipment and plan of haulage are worked up in great engineering nicety to fit local conditions and physical characteristics, the operation of the underground work is frequently under the absolute control of the mine foreman or mine manager, as he is sometimes called, with his assistant foreman or face bosses.

MINE FOREMAN HAS A LEGION OF DUTIES

As the mine foreman is the chief underground official, the problems in underground management in a bituminous mine may best be understood by a brief consideration of the work of these officials and their assistants.

The supervision of the miners, or loaders, as they are usually called, who work alone one man to a room or to an entry or two men working alternately in two or three rooms involves a visit, usually twice a day, to inspect the quality of the work, see that refuse is properly gobbled, see that only clean coal is loaded and that the miner is gobbing his bone, advise him on location and slant of shotholes and the loading required, examine the track in the room, inspect his timbering, sound the roof, listen to any complaints, dicker with him as to the amount of work, if any, on slate or rock which is to be done by the day or job, reach an agreement on all claims for allowances for dead work and take up grievances with the pit committee.

As the loaders and also the machine cutters are paid by the mine carload, or on a tonnage basis, the foreman is relieved of the necessity of driving the men and his relations with miner are generally cordial. The assignment of the men to their working places is simpler than might be supposed, because a miner, having once been given a room, remains in it day after day, advancing it so slowly that he may remain in his place for several months before it is completed.

The foreman must settle any disputes or complaints with reference to the conditions at the working place

and arrange for the substitution of new men if for any reason the loader quits. The foreman must supervise the cutting machines, co-ordinating in the miles of underground workings which he supervises, the blasting, cutting, loading, and hauling of coal so that delays will be reduced to a minimum. He must lay out, follow up and inspect the work of the company men who excavate rock in entries, lay track, place trolley wire, set timbers, build permanent walls for roof support, build temporary walls for ventilation and place brattices.

Added to these duties, the foreman and his assistants direct traffic. The supply of cars to the miner, one of the most vital operations in underground management, is handled chiefly by the motormen, with supervision, when necessary, from the foreman, or his assistants. To a large extent the motormen in hauling the trips on the main line as well as the motormen in gathering cars use their own judgment as to the number of cars in a trip, the number of trips, and time of making trips, with a view to satisfying the requirements of the miner and the convenience of the operating crew at the tippie or at the bottom of the shaft.

The foreman and his assistants must supervise the removal of the pillars in second-mining or pillaring operations. The development plans, including the size of the rooms and width of pillars, are generally determined by the engineers and officials. Many questions of local nature having to do with the daily operation are of necessity left to the judgment of the foreman.

Generally also the foreman has the responsibility for endless other details such as pumps and drainage, ventilation, the roadbed, the decision as to the quantity and location of timbering, the care of the injured, and the clean-up of rock falls. He must always bear in mind the safety of the employee, the protection of the mine and the obtaining of the largest and most economical production possible.

Some companies insist upon a high standard of qualifications for assistant foremen or face-bosses. Frequently they are required to hold certificates of competency—given only after rigid examinations in accordance with requirements of the mining law. Other companies are not so exacting and the men for these

positions are selected by observation for their experience as miners and ability to direct the work of others. Unfortunately in only too many mines even these requirements are ignored and the assistant's sole qualification is his mining experience. The responsibilities of the position are too great for any but the best men available, and the presence of so many incompetent men indicates a sore need for better underground management, especially seeing that as many as 150 men may be working under one of these assistants.

MORE FOREMEN OR GREATER CONCENTRATION

The solution at first thought, would be in a larger number of foremen. Our examination, however, showed that conditions are by no means satisfactory even where a few are found working under the supervision of a face boss. The solution of the problem of more efficient underground management must be found rather in developing such machinery and advanced methods of planning and control of standardized production as will correspond more nearly to those being worked out to such a high degree in many industrial establishments.

In most industries remarkable progress has been made during the last century in the development of machinery to replace slow and arduous hand labor and to reduce production costs. The bituminous-coal mining industry is reducing manual labor through the introduction of machinery and in that process has at last reached the final stage. The first was the use of undercutting machinery. The importance of the problem, both to the workman in lessening his toil, and to the consumer in reducing the cost of coal, is evident when we consider that some 70 per cent of the cost at the mine is labor and more than one-half of this labor is for cutting and loading coal into the mine cars.

This transition will, of course, decrease the human labor needed at any given point or for any given production. This is inevitable and desirable. However, unlike the introduction of other automatic machines into industry, such as the spinning frame, the transition naturally will be slow because the machinery will have to be adapted to the physical condition of different mines. Furthermore, instead of requiring labor of less skill the miners left will be of a higher type, for to

Mine Parting

Always the despair of superintendents, mine foremen, miners and efficiency engineers. Heretofore is lost by men and locomotives alike. Here the old problem of the railroad yard is duplicated but not solved. It can be corrected only when double track replaces single so that going traffic does not interfere with returning. At the mine here illustrated much effort has been made to avoid the delays and heartaches that the word parting spells.

operate the machines will require greater initiative than is demanded of those who ply the pick and shovel, which is now the principal tool of the coal miners. Furthermore, the surplus labor, if any, will not go a-begging. In other industries men are needed who are trained to perform such work as shoveling coal.

The industry will slowly substitute mechanical for hand loading just as it will also develop coal storage, thus regulating production and lowering its costs. Development of enough low-cost operation to supply the demand will automatically eliminate the high-cost mine, the snowbirds and the wagon mines which under existing conditions in periods of car shortage absorb such a large portion of the transportation service as to lower the working time of the better mines, thus unduly increasing their costs.

As will be brought out later in this report, the change in the method of mining from man to machinery, while yet in its infancy, has been accomplished already. Among the mines observed, two were practically machine-operated as far as the cutting, drilling and loading of coal were concerned. In one of these only four hand loaders remained on special work, and the other mine was doing all its loading by machinery. In a number of other mines machine loading was in varying degrees of operation. In one mine machines had been used for loading during a period of nearly ten years. One company has purchased seven loading machines to use in a new opening.

Semi-Bituminous or "Smokeless" Coal Best As Substitute for Anthracite

SEMI-BITUMINOUS coals, embracing the "smokeless" Pocahontas, New River and Georges Creek coals of Virginia, West Virginia and Maryland and the smokeless Clearfield coal of Pennsylvania, probably are the best adapted of any "soft coal" for use as a substitute for anthracite, states Rudolf Kudlich, assistant to the chief mechanical engineer of the Bureau of Mines, in Serial 2520 of the Bureau, recently issued. If properly fired and drafts properly regulated, these coals can be burned without smoke and will deposit very little soot in the furnace and smoke pipe or chimney.

These smokeless coals are available in practically all the Eastern markets where anthracite is the customary fuel. They are higher in heat value and usually contain less ash than anthracite, and as a general rule can be bought considerably cheaper. Because of the higher heat value, if such coal is sold at two-thirds of the price of anthracite, the purchaser actually gets almost twice the amount of available heat for his money. With proper care in operating his furnace he can realize this saving entire, but even with careless handling much expense will be saved.

All coals of this class are extremely friable and cannot be graded in size like anthracite. A large proportion of the coal as delivered will be in small sizes grading down to dust. Many people not accustomed to this coal are reluctant to accept it, considering the fine sizes as dirt. As a matter of fact, this fine coal contains less ash and will give off more heat than the large pieces. This coal has the property of "coking," that is of fusing together when heated, so that if properly fired it will form large pieces which do not fall through the grate to the ash pan. Because of its large percentage of fines,

this coal is somewhat dust and dirty to handle dry. If well wet down before it is put in the cellar, and if the front of the pile in the bin be kept moistened with an occasional bucket or two of water, this dirt can be largely eliminated.

Device for Prying Open Endgate of Car

BY CECIL ROWE

Mining Engineer, Kinney Coal Mine, Tokay, N. M.

FREQUENTLY when discharging end-dump cars on a horn dump, the gate hook will fail to engage the lugs on the car door and the car will tip over with the door closed. When this happens it is necessary to use a bar or some other instrument to pry the door open. Usually the rock comes against the door with such force that the latter is opened only with difficulty. Much time is lost even if a satisfactory pry is at hand, which is not always the case. To overcome this difficulty I have used the device shown in the illustration, with excellent success.

It consists of two 2 x $\frac{3}{4}$ in. pieces of band iron, one piece forming the handle with two holes drilled in it, one hole for bolting to the upright irons and the other for fastening to the second and hooked piece of band iron. The hook is engaged in one of the door lugs, and by pulling down on the handle enough force is exerted on the door to pull and hold it open until all the rock has left the car. At the movable joints $\frac{1}{2}$ -in. bolts are used.

HOOK FOR OPENING CAR DOOR

Most hooks are planned to open the car door as it drops forward in the dump. This is intended for opening the car when tipped.

It will be noted in the illustration that no gate hook has been provided. In this case the cars were dumped into a long chute and all cars were tripped over with the door closed because dumping with the door open caused the rock to jump over the sides of the chute, endangering nearby workmen. The procedure consisted of pushing the loaded car of rock into the horn dump, allowing it to tip, and then prying the door open with the device shown. Wooden cars were used with a small hole cut in the upper center of the door, this hole serving to engage the hook.

WOULD DISSOLVE COAL AND USE IT AS OIL.—In an address given at Birmingham, England, Oct. 15, K. N. Moss, professor of mining at Birmingham University, stated that a Japanese worker claimed to have discovered a solvent—hydro-naphthalene—that would dissolve 70 per cent of the coal substance. Mr. Moss called attention to the progress being made in researches aiming at the conversion of coal dust into liquid fuel by the use of solvents. In the mining department of Birmingham University the hydrogenation of coal was being investigated.

THE WEIGHT OF 1 CU. FT. OF SIZED COKE is as follows for the various sizes: Egg, 30 lb.; stove, 34 lb.; nut, 36 lb.; pea, 38 lb.; run-of-oven, 31 lb.; foundry, 25 lb.; water gas, 30 lb.

*Pikeview Mine of Pikes Peak Consolidated Fuel Co.**

At Pikeview Mine Pillar Drawing Raises Extraction to 95 per Cent; Formerly Only Two-Thirds as Much

Cutting Back Abandoned Coal 30 Ft. at Time, Allowing Roof to Cave by Sections, Works Well in Lignite Mine of Pikes Peak Consolidated Fuel Co., Giving Property New Lease on Life

NINETY-FIVE per cent extraction! What a production record that is for an underground coal operation! And how few mines attain it! The Pikeview mine of the Pikes Peak Consolidated Fuel Co., in the edge of Colorado Springs, Colo., is one of the few. There, extraction has been raised to approximately 95 per cent by a method of pillar pulling. The owners are getting all the coal any reasonable and well-informed mining man could expect out of the property—a good deal more than had ever been hoped for until Henry Thomas, mine superintendent, took charge. Today vast areas of thick pillars, long abandoned as lost coal, are being pulled in regions close enough to the main shaft to effect a marked reduction in underground haulage costs.

The 130-ft. shaft of the Pikeview mine, five miles north of Colorado Springs and in plain sight of Pikes Peak, the best known mountain in Colorado, taps the 12-ft. Laramie seam of lignite at a point not far from the southeasterly edge of the coal deposit. The mine is an old one, and operations had been carried back under the foothills to the northwest of the shaft nearly two miles in a rather narrow and restricted zone. Haulage was getting long. This was a consideration even though the grades against the loads were not heavy.

Extraction was not a bit better than the average for lignite operations in Colorado—something like 60 per cent at best. This figure may look quite satisfactory

to many a coal operator in fields such as those of Illinois and Indiana, where little more than 50 per cent of the coal is removed and where one well-known string of mines runs down to the extreme of 39 per cent extraction. But it looked bad to the Pikes Peak Consolidated Fuel Co.

LEFT NEARHAND COAL AND SOUGHT MORE REMOTE

The mine was operated on the room-and-pillar system with 21-ft. rooms, 300 ft. long laid out on 45-ft. centers. This left the “worked-out” areas full of 24-ft. pillars. To extract the average 300 tons of coal a day in those years it became necessary to work far back under the hills. Something had to be done.

An effort at one time was made to rob some of these pillars. Machines went in and made long rib cuts from the old faces out toward the room necks. Some easy coal was recovered. Then, disliking to work machines in rooms where pillars were growing thin, the men began a little solid shooting, by which they made breakthroughs at 40-ft. intervals in each pillar and by which the remaining sections of the pillars were nibbled so that they were finally left with long, uneven, bias faces (Fig. 1).

The roof over this coal is a crumbly sandstone covered by a strong cap rock a few feet above. Ordinarily 18 to 24 in. of top coal is left to hold it. Little effort was made in the first pillar-drawing experience to brush this roof coal. The characteristic bottom under the

*Mountain to rear of mine is Pikes Peak, 14,147 ft. high.

FIG. 3

Bottom Landing

Taken from load side. Fourteen hundred tons can be caged in eight hours with the same equipment that used to handle 700 tons at best. The main entry has been concreted back 100 yd. and painted white. Henry Thomas, mine superintendent, is standing on extreme right. He believes a neat appearing mine makes the miners disposed to keep their workings in shipshape order.

FIG. 4

Removing Pillar

Note how the ribs were left arching the roadway. The pillar is being drawn back from room to room. The coal obtained is largely lumps which are well suited for the demands of the domestic market. When this coal and that from roof and floor is loaded the working place is left till the roof falls. The stratum over the coal is a crumbly sandstone, but a strong cap rock occurs a few feet above. Note how two cars are placed at one time, making the placing and gathering of cars an easy task.

FIG. 5

A Gathering Unit

The high car makes possible a narrow and short car of 3,500 lb. capacity. Note the braces on the side of the car to give support to a flat flare, giving increased carrying capacity. The illustration gives a good idea of the character of the roof.

FIG. 6

Fleet of Coal Trucks

The size of the local domestic coal business of the Pikes Peak Consolidated Fuel Co. can be judged by the fleet of trucks. About 70 per cent of the coal goes to keep the home fires burning. The fine coal is used to reduce the gold ore of the Cripple Creek region. The coal eventually may be pulverized and used in that form or possibly a portion of it will be made into coke.

volume of screenings is taken by a local gold-ore reduction mill operated by the interests that control the coal mine. That particular supply, which averages 6,000 tons a month, fills a need for a long-flame coal for use in furnaces roasting Cripple Creek ore.

The lignite from this mine contains 22.04 per cent of moisture, 42.10 of volatile matter; 48.34 of fixed carbon and 9.56 per cent of ash. It has a thermal value of 10,441 B.t.u. It has given satisfaction even as pulverized fuel. During a recent American Society of Mechanical Engineers code test at Pueblo, Colo., with a 456-hp. Stirling water-tube boiler this particular coal was fired for the prescribed length of time. The engineers' report showed a boiler and furnace efficiency of 68.67 per

cent. There is a possibility that some day an electric power plant will be built at the mine to burn pulverized Pikeview coal. The company also is convinced that this lignite will coke successfully and that if the market develops a large volume of it can be put through the ovens with profit.

So there is a vital company interest in what Superintendent Henry Thomas and his two foremen, H. O. Knapp and C. Meerdink, are doing out at Pikeview mine to recover great tonnages of abandoned coal. And it is with great interest that the company has seen the mine develop under Thomas' direction, from a 700-tonner to an operation having twice that daily capacity.

Experience in Creosoting Mine Timber

IN RESPONSE to inquiries, Thomas R. Clark, of the Clark Coal & Coke Co., who wrote the article "Creosoting Experience at Two Small Mining Plants," appearing in the issue of *Coal Age* of Sept. 6, p. 357, informs us that: "We find a number of men are unable to work around creosote on account of its pungent odor, and this is particularly true when that preservative is heated. We have met this difficulty by employing different men at the treating plant and we have found several that the creosote does not in any way affect, and these men have been assigned to the duty of dipping the timber.

"Carbosota, the preparation of creosote that we have used exclusively, penetrates timber easily and does not leave it sticky like many treated railroad ties I have seen. By allowing the timbers to stand out in the weather for thirty or sixty days, the creosote is entirely absorbed by the wood and treated and untreated timbers can be handled without any noticeable difference. Strange to say I have found some men to whom the smell of creosote is attractive.

"Speaking of the effect of fire on creosoted timber the preparation we use is highly inflammable, as we discovered when we attempted to burn out some of the iron barrels in which it was shipped. Undoubtedly the timbers are more easily fired than the untreated

ones, but it seems that in the mine they soon become damp and, therefore, not susceptible to any small flame. At the Hanna City mine water is running down the sides of the shaft at practically all times, so that it would be almost impossible for this material to be set on fire."

Propose Adoption of 20-Ton Cars In Movement of Welsh Coal

An important step has just been taken by one of the British railway groups with the view of effecting economies in the rail transportation of coal. The Great Western Ry., which has practically a monopoly of the Welsh coal traffic, has been employing cars of ten-ton capacity, but having experimented with cars that will carry twenty tons, is satisfied that these higher capacity vehicles should be brought into general use without undue delay. A census taken by the Board of Trade in 1918 disclosed that there were approximately 116,000 privately owned coal coars in south Wales, mostly of ten tons capacity, and it is recognized that before any change can be made many difficulties have to be overcome at the pits and at the docks. As an inducement to the wagon owners, and irrespective of the fact that railway operating economies will not accrue until a considerable number of high-capacity cars are available, the Great Western Ry. announces that it is prepared at once to allow a rebate of 5 per cent on rates in respect of coal class traffic conveyed wholly over its system in fully loaded 20-ton cars.

How Skillful Use of Drill Press Minimizes Consumption Of Time in Repair Work

Shaping the Drill for Efficient Work—Changing the Cutting Edge for Soft Metals—Preparing the Work and Locating Hole Centers—Making a Flat Drill

BY GUSTAV H. RADEBAUGH
Mechanical Department, University of Illinois, Urbana, Ill.

TO GET the most out of the drill press the tradesman's methods of operation should be employed. Construction and repair work on broken castings and damaged frame parts of mine mechanical equipment will generally call for drilling holes. When repairing mine machinery it will be found that several types of metals are used in their construction. Soft and hardened steel, cast steel, cast iron, bronze, brass, malleable iron and aluminum are all very commonly used in the construction of mine equipment. Therefore to get efficient results from a drill press it is essential that the drilling qualities of these metals be understood.

Several types of power and hand drilling machinery are used by tradesmen when doing repair work. It is important for the mine repair man to become acquainted with those tools, as it makes the planning and completion of a job much easier. Styles of these drills are shown in Fig. 1.

The hand drill is one of the most useful tools in the repair shop for drilling holes up to ¼-in. diameter. When drilling holes of small sizes the drill must be driven at a high speed to prevent the drill point from breaking. Many hand drills are supplied with a set of twelve drill points which are held in the wooden handle when not in use. This type of drill is much better for small drilling than the combination post drill, as a greater drill speed can be obtained and the feed pressure more easily controlled.

When it is impossible to get the job to the combination post drill when drilling holes ¼ to ⅜ in. in size, the breast drill is used. If holes larger than ¼ in. are being drilled to any depth in cast iron or soft steel a ½-in. hole should be drilled first with the hand drill. This operation makes drilling with the breast drill much easier. A spirit level is frequently supplied on this type of drill to assist the operator in drilling straight holes. When making holes larger than ⅝ in. considerable pressure must be applied to the drill to make it cut. The Armstrong Packer ratchet drill is designed for the larger sizes of drills. A brace is provided to support the ratchet and drills, the pressure being applied by the threaded nut on the top of the ratchet.

When drilling holes in pipe work, where a chain can be passed around the work, the chain drill attachment is used. It is driven by an ordinary carpenter bit brace. The feed to the drill is obtained by a screw arrangement which tightens against the chain. This tool will be found useful in drilling holes ranging from ⅝ to ⅞ in.

Many styles and sizes of post drills are on the market, but the one provided with a hand and power drive with automatic feed will be found as effective as any. When it is not necessary for the average mine shop to be provided with the best of these post drills a medium priced machine will give good service.

To make it possible to get the best service from the post drill press a few drills and tools must be provided. Fig. 2 shows several such tools. If the shop is provided with this equipment the heaviest or most delicate drilling job should not be too difficult. Post drill presses of different design require drills with special shanks. Care should be exercised when ordering drills to be sure that they fit the press for which they are ordered. Notice the shank design on the Coes drill and the Prentice drill. The other four styles are standard, but they require chucks or holding sleeves, and are not commonly used on this type of drill press.

The taper shank drill is held in the drill press spindle with the steel sleeve. This is the type of drill used in most commercial shops. The straight-shank drill is held in a chuck. They come in sizes from No. 60 up. It is not good practice to use straight-shank drills larger than ½ in. Chucks are provided with a shank that fits into the drill-press spindle. The straight-shank drills should be used in the mine shop. Justification for recommending the use of the straight-shank drill up to ½ in. for the mine repair shop is the large range of drill sizes for taps. The cost of this drill also is lower. If the shop is going to drill and tap holes for machine screws, such as found on power and mining equipment, it is obvious that the correct sized drills must be on hand.

The sizes of screws are somewhat confusing, as there are several standards existing, which many times makes the task of replacing screws on repair work an unpleasant and unprofitable job. To explain how the size of a medium screw is gaged and the drill chosen for the tap we can remove a screw from a job and by noting it in the drill tap gage, as shown in Fig. 2, it

TAP DRILLS

3	4 1/2	3	3	3

FIG. 1—VARIOUS TYPES OF POWER AND HAND DRILLS FOR SHOP MECHANICS

is found it fits in a certain hole. On referring to the machine-screw list we find that this is the body size for a No. 12x24 screw, meaning number 12 size and

24 threads to the inch, requiring a tap drill No. 15. This means that if this job is to be done a straight-shank drill, as shown in the drill-block set, must be supplied, as these sizes are not made with special shanks. These drills are sized in numbers ranging from 1 to 60, and are sized to fit all standard machine screws.

A simple and convenient way of measuring these drills is by using the L. S. Starrett drill and tap gage, which is used to determine the size of screw, tap drill and body drill. Notice the sizes of machine screws and the tap-drill sizes marked on this gage. Drills used to drill a hole for tapping are called tap drills. Another useful tool is the fractional drill gage. This is used to measure drills from $\frac{1}{8}$ to $\frac{1}{2}$ in. by $\frac{1}{32}$ in. These gages are not expensive and will be found useful in the tool box of any mechanic.

Flat-head screws require a countersunk hole; the countersinks shown are provided with a straight shank for a drill chuck and a bit-brace shank for the carpenter brace. For light countersinking the breast drill is oftentimes used to drive the countersink.

FIG. 2—DRILLS AND DRILL-PRESS EQUIPMENT NECESSARY FOR THE SMALL MINE MACHINE SHOP

In Fig. 3 three types of drill chucks are shown. The two chucks on the platen of the drill press cannot be used in the post drill unless the spindle has been bored out so that the taper chuck shank will fit. On this machine this has been done and the little time consumed on this operation has been worth while. The practice of having a setscrew on the spindle of a drill press is obsolete and is very dangerous. A tragic story could be written on the many accidents the setscrews on drill spindles has caused.

The post drill should be clamped to the post or wall with four $\frac{3}{4}$ -in. carriage bolts with washers. It should be located so that the chuck will be level with the operator's chest. This permits free operation.

Few operations on tools in a shop are more important than the grinding or sharpening of drills. To

FIG. 3—THREE DIFFERENT TYPES OF DRILL CHUCKS COMMONLY USED

obtain satisfactory performance the cutting edges must have a proper and uniform angle of 59 deg. with the longitudinal axis of the drill. They must be of exactly equal lengths, and the lips of the drill must be sufficiently backed off or cleared. If this clearance is insufficient or imperfect, the drill will not cut. A simple method of determining the clearance is to set the point of the drill on a flat surface, holding a rule parallel with the drill; by revolving the drill its clearance can be checked, as well as the height of the cutting lip, which should be equal.

DRILL LIST FOR TAPS FOR AUTOMOBILE MANUFACTURER'S PRODUCTS

$\frac{5}{8}$	20	$\frac{7}{8}$	1	14	$\frac{1}{2}$
$\frac{3}{4}$	18	1

FIG. 4—GRINDING THE CUTTING EDGES
Most drills work best when the cutting edges are ground at an angle of 59 deg. with the longitudinal axis.

When grinding a drill, support the drill on the index finger, as shown in Fig. 4. By doing this a grinding balance and position are more accurately maintained. It is a good plan to have a drill in the shop that has never been reground for use as a sample to gage by. When grinding, do not draw the temper on the drill. To prevent this it is always good policy during the grinding operation to place the drill in water to cool it. Endeavor to preserve the original form of the drill. It has been ground by the manufacturer to insure rapid and satisfactory work.

Many times when a drill has been considerably shortened through use, the center becomes thicker, which causes the drill to work hard. Drills are made with the center thicker toward the shank to strengthen the drill. To overcome this, the center should be thinned, care being taken to remove equal amounts of stock on each side, so that the point will be kept central.

Drilling brass and babbitt requires the changing of the drill-lip clearance angle; often an operator finds difficulty in drilling these metals. The angle of keenness causes the drill to dig into the work. This crowds the drill to the point of jerking the work from the platen or throws the belt. To prevent this, eliminate

FIG. 5—CHANGING THE LIP EDGE FOR DRILLING SOFT METALS
Grinding the lip edge in a plane parallel to the axis of the drill changes the angle of keenness so that the drill has the scraping action necessary for cutting the softer metals.

FIG. 6—DRILL PREPARED FOR CUTTING BRASS

The cutting edges of the drill look flat when properly shaped for cutting brass. This allows the drill to have a scraping action and thus operate without chattering.

the angle of keenness on the drill lip by grinding the lip edge parallel with the axis of the drill as shown in Fig. 5. Note that the grinding is being done on the side of the wheel and not on the face. It must be understood that if the drill after being ground for brass is to be used for steel or iron drilling, it must be reground as explained in Fig. 4. When grinding a drill for brass a close inspection should be made after the grinding operation. Note in Fig. 6 how the cutting edge of the drill looks flat. A flat surface gives the scraping action which eliminates all the trouble when drilling soft metals.

Some results of improper grinding are shown in Fig. 7. If a drill has been ground with the point in the center but the angles of the cutting edges are different, the drill will bind on the side of the hole opposite to that side of the point which is cutting, which results in too large a hole and all the cutting will be done by the one cutting edge, as shown in Sketch A. If the drill is ground with equal angles but with the cutting edges of different lengths the hole will be drilled too large, as shown in B.

When making repairs on machines it often is necessary to join broken castings with steel brackets or straps. One of the common difficulties in making this type of repair is to drill the holes accurately. Inaccurate drilling makes it impossible to insert bolts or cap screws without filing out the holes. This indicates that not enough care was exercised in locating the drilling centers. Locating the drill center for a bracket job

FIG. 7—IMPROPERLY SHARPENED DRILLS

A shows how the drill crowds to one side when the angle of the cutting edges are different. B shows the results of a drill ground with the cutting angles equal but the edges of different lengths.

such as is shown in Fig. 8 can be made a short job by following the practice of the trained mechanic. If the holes have not been previously drilled in the bracket, this should be done.

Good judgment must be used in properly locating these holes in relation to the part being patched. The surface on the job where this drilled bracket is to be located should be well chalked with starch or carpenter's chalk. The bracket should be put in place next and with a scribe or scratch awl the outline of the holes made on the chalked surface, as shown in Fig. 8. If these holes are going to line up with the holes in the bracket, it is obvious that the hole must be drilled in the center of this layout. Too many times jobs of this kind are not properly prepared for accurate drilling. Never drill a hole in a job unless the location desired for the hole is established by a center punch mark. The center punch is shown in use in Fig. 9. The finished layout is shown in Fig. 10.

This job is now ready to be drilled, but only to a depth which will permit checking the drilling center with the layout. It is common for drills to "run" or change the drilling center from the original layout. This is the cause of many difficulties when fitting bolts or screws in the drilled holes. The holes do not line up, so it becomes necessary to file until a fit is made. To guarantee a good alignment of holes it is necessary to keep the drill within the layout circle. To do this the drill should be fed into the work to a depth of half the height of the drill point, as shown in Fig. 11. After

FIGS. 8, 9 AND 10—PREPARING THE JOB AND LOCATING CENTERS FOR HOLES

After chalking the metal, holes are scribed from the template and the centers for the holes located and punched.

FIGS. 11 AND 12—STARTING THE WORK AND CORRECTING THE CENTER

The drill is fed into the work about half the depth of the hole. If the hole centers are not in the proper location they may be shifted with a round-nosed chisel.

this is done the drill is lifted from the work and the drilling center is compared with the layout circle. If the drill has "run," it will show up very clearly, as the partly drilled hole will be to one side of the layout circle.

Our problem, then, is to bring the drilling position back to the correct center. This is done as shown in Fig. 12, where a round-nose chisel is used to change the center. This operation is known as drawing a hole. A hole cannot be drawn if the drill has penetrated the metal to the full diameter of the drill. It has been stated that the drill should be fed into the work only half the depth of the drill points. In doing this several attempts can be made in the drawing operation before the hole is drilled to full diameter. After the drilling position has been drawn to the center of the layout circle, the hole is ready to be drilled.

In reviewing the drilling job we have followed the trade practice of the mechanic: (1) Lay out the hole, from template or drilled bracket, using scriber or scratch awl; (2) center the job with the center punch; (3) drill the hole to check for position. If the drill "runs," the correct position is regained by using the round-nose chisel or gage. With the drilling position correct, the job is now ready to drill.

The speed and feed of drills used in mine repair drilling can be determined by actual practice and by exercising sound judgment. In commercial-shop practice when drilling steel a peripheral speed of 30 ft. a minute; for cast iron, 35 ft.; for brass, 60 ft., using a

feed of 0.004 to 0.007 in. per revolution for drills larger than $\frac{1}{2}$ in. diameter is the prevailing practice. Another example of speeds for drilling is the comparison of the $\frac{1}{4}$ -in. drill revolving at the rate of 611 r.p.m. and the $\frac{3}{4}$ -in. drill revolving at a rate of 203 r.p.m. This speed will give the peripheral speed of 40 ft. per minute.

Often the work done on a drill press is large enough so that it will not move under the action of the cutting drill. However, many drilling jobs necessitate clamping the job to the platen of the drill press to insure accurate drilling and to prevent the breaking of drills. One of the most convenient clamps is the malleable iron screw clamp shown in use on the drilling job in Fig. 13. Note that on this job a block of wood is being used under the job, which protects the drill-press platen. Another scheme that is used on short pieces of stock being drilled is shown in Fig. 14. Many times pieces like this are held with the hand, but this is bad practice. If the drill should catch, there might be danger of injury to the hand. In drilling small holes the job may be held by hand, but it is good practice always to clamp a job when drilling holes larger than $\frac{1}{8}$ in. and thus avoid any possibility of accident or damage.

Many drills are broken and hands injured by drilling a bent bracket without holding it with a wrench or clamp. In Fig. 15 a typical job is shown. This type of job is known to the tradesman as one of the most dangerous of the drilling operations. It is better, then, in order to prevent the breaking of drills, that all

FIGS. 13, 14 AND 15—THREE METHODS OF HOLDING THE WORK ON THE PLATEN

A good mechanic can usually be recognized by the ways he handles his materials and prevents accidents and damage to equipment. Many jobs require special means for clamping or holding on the drill press.

TAP DRILLS FOR PIPE TAPS

1 1/8	11 1/2	1 1/8			

bracket jobs be securely clamped to the platen or the job held firmly with the monkey wrench.

Hardened steel may be drilled by using turpentine or kerosene; on soft steel and wrought iron, use lard oil or machine oil; with malleable iron, lard oil or machine oil should be used, and for aluminum and soft alloys, kerosene. Cast iron should be worked dry.

In Fig. 16 a job on hardened steel is shown on the drill press; a 3/8-in. hole is being drilled. The drilling of hard metal is facilitated by using turpentine as a cutting compound and by grinding off the sharp angles of the cutting edge of the drill, as explained for cutting brass and soft metals. This permits a heavy feed without chipping the edge. Practice will prove that somewhat slower speed of the drill will be required for drilling hardened steel than for soft steel.

In drilling holes in glass, use a brass pipe having an outside diameter equal to the size hole required. This pipe should have a peripheral sped of 100 ft. per minute. Use carborundum 80 to 100 grit or a valve grinding compound with oil. This mixture should be placed between the end of the pipe and the glass.

FIG. 16—DRILLING HARD STEEL

For hard metals a heavy feed is necessary at a slower speed than for soft steel.

FIG. 17—SPOT FACING

This is done with the counter-boring drill. The pilot should fit the hole closely so as to prevent shifting.

The glass must be supported by felt or rubber cushions not much larger than the hole to be drilled. When filing glass use turpentine. Holes up to 1/2 in. in diameter can be drilled in glass with a flat drill properly hardened. Use a mixture of turpentine and camphor for the lubricant.

Machined spots around a hole on machine frames are provided to give a true flat surface for the head of the screw. This operation is done with the counterboring tool shown in use in Fig. 17. This tool is provided with a pilot which guides the tool. Sizes of counter bores are gaged by the diameter of the surface it will smooth up and the size of the pilot. This tool has a shank that fits the drill chuck and is driven at about the same speed as a drill of equal size.

It sometimes happens that a hole must be drilled, but that a drill of the required size is not on hand. A shop that is equipped with a forge, however, can make up the size drill required. It is common practice for a commercial shop to make a flat drill to take care of

FIGS. 18, 19 AND 20—MAKING THE FLAT DRILL

It is important that the material for the flat drill be forged at the correct temperature and the lips shaped to the proper angle by filing. The temper color is made more easily visible by first cleaning with emery.

some drilling job that requires drills of special size. Flat drills must be made from high carbon steel. An old round file can be made into a flat drill. The stock can be forged to shape as shown in Fig. 18, but care must be exercised in working the steel at the correct temperature. The diameter of the stock regulates the range of the size drill that can be made.

The newly forged drill is next filed to size, checking the size with the caliper, as shown in Fig. 19. The angles are the same as the twist drill. It will be an advantage to have a twist drill by the job to check the angles and cutting edges during the filing operation. The next operation is the tempering of the newly shaped drill. When tempering for steel drilling, heat the drill point to a cherry red and dip in water; enough

heat should be left in the shank of the drill to draw the temper. The point can be polished with emery cloth to make the temper color more visible. Quench when the temper shows up a light straw. These are the same operations that are followed when tempering a cold chisel, except that the temper color of the chisel is blue. If a flat drill is used for drilling glass, heat to a cherry red and harden in sulphurous acid.

The drill tables will be found useful around the drill press and in the mine shop. This is the type of information the commercial shopman has around him to help solve his drill-press problems. These tables give an opportunity for the mine-shop workman to take advantage of this valuable information and have it always available for any kind of drilling.

French Mines Soon Will Be in Full Operation

REMARKABLE progress has been achieved in the reconstruction of the French mining industry, systematically destroyed in war-time by the invading Germans, according to George S. Rice, chief mining engineer of the Bureau of Mines. Mr. Rice has just returned to this country, after completing a study, occupying several months, of conditions in the mining industries of France, Great Britain, Belgium, Germany, Poland, and Czechoslovakia. As a result of the splendid engineering skill employed in the restoration work, some of the finest coal-mining plants in the world have been constructed in the north of France. Thousands of miners' houses have been built, replacing those destroyed. These houses are quite attractive and most of them have gardens, which have been redeemed from trenched and blasted ground.

Much attention has been paid to welfare projects, with the result that the miners of northern France are undoubtedly better housed than those in any other part of the world. Underground, the mines have been recovered to such an extent that they are producing about 70 per cent of the normal coal output. When all the water has been pumped out of the mines, the coal production of northern France will be much greater than before the war.

World's Coal Output, January-June, 1923, Well in Advance of Last Year

World production of coal during the first half of 1923 amounted to approximately 666,000,000 metric tons, according to a summary of data received by the U. S. Geological Survey up to Oct. 15. This is an increase of about 79,400,000 tons, or 13.3 per cent over the corresponding period of last

year. All the countries listed, with the exception of Austria, Czechoslovakia and Germany, have increased their production. The most notable increases were in the United States, the United Kingdom and Poland. The proportion contributed by the United States was 44 per cent of the total.

The world total of 666,000,000 tons includes an estimate for Germany based on complete data for January and February and incomplete data thereafter. It also includes estimates for those countries, representing about 5 per cent of the whole, for which no figures of production were available. The following table, prepared by W. I. Whiteside of the Section of Foreign Mineral Reserves, is subject to revision as final official figures are received. Lignite and brown coal are included; where possible they are shown separately.

PRODUCTION OF COAL IN PRINCIPAL COUNTRIES OF THE WORLD, JANUARY—JUNE, 1923
(In metric tons of 2,204.622 lb.)

Country	Metric Tons	Per Cent of Total
North America:		
Canada.....	7,912,610	1.19

New Equipment

Reel and Trolley Switch Combined In Locomotive Controller

THE new type LM 67 controller recently developed by the Goodman Manufacturing Co., of Chicago, combines the motor controller and a transfer switch for use with locomotives having both trolley and cable reel. This transfer switch is operated from the same shaft as the reverse lever, the switch reverse lever and controller handle being within 10 in. of each other. When the controller is on any of the running points it is impossible to operate the transfer switch. In this way the danger that always attends the throwing of the switch from the reel to the trolley, or vice versa, when taking power, is eliminated. Larger space is provided in the cab of the locomotive by the use of this controller and the elimination of the large transfer switch usually found on most trolley and cable-reel locomotives.

Adding the safety switch has taken nothing from the operating results of the controller itself. Interlocking the control and reverse transfer handle prevents changing the direction of the locomotive travel or switching the source from which the power must be taken—trolley or reel—without first moving the controller handle to the "off" position.

The three contacts and fingers making up the working parts of the safety switch are interchangeable with other fingers and contacts of the controller. In other words, all fingers and contacts of the main cylinder, reverse drum and safety switch are interchangeable. Easy adjustment of all fingers is made by screws, specially treated to resist rust. These screws keep the fingers always in proper position.

A large blowout coil in the bottom of the controller concentrates great energy where the large

arc is formed. Before the arc of either switch or controller cylinder has strength enough to do severe damage, it is destroyed. This blowout coil is heavily insulated and is very rugged, in order to stand up to the duty required.

Power-Operated Blacksmith Hammer

THE blacksmithing hammer is a comparatively new device which is finding a place among the labor-saving equipment used around the coal mines. This mechanical helper will replace one or two human strikers in any blacksmith shop. The hammer strikes a maximum blow about four times as heavy as that of the average striker and is intended particularly for forging work that is too small to be done under steam hammers. The smith has complete control over every blow by means of a treadle running around the anvil.

As high as 140 blows per minute can be struck and for this reason work can be done more quickly and with only one heating. The anvil is of special patented design, having a planed base and a stand with adjusting screws to move the anvil forward or backward as required. The hammer requires but 1 hp. to drive and on a line shaft with other tools the power absorbed will average less. The individual motor-driven unit is most compact and offers numerous advantages. The motor is mounted on a small stand in the base and geared to a large driving gear on the main shaft.

FIG. 1—CONTROLLER
WITH COVER

Note how conveniently the transfer switch handle is located with respect to the control handle, with which it is interlocked.

FIG. 2—INSIDE VIEW, ARC
DEFLECTOR OFF

To operate the transfer switch, which permits taking power through the trolley pole or reel cable, the control handle must be in the "off" position.

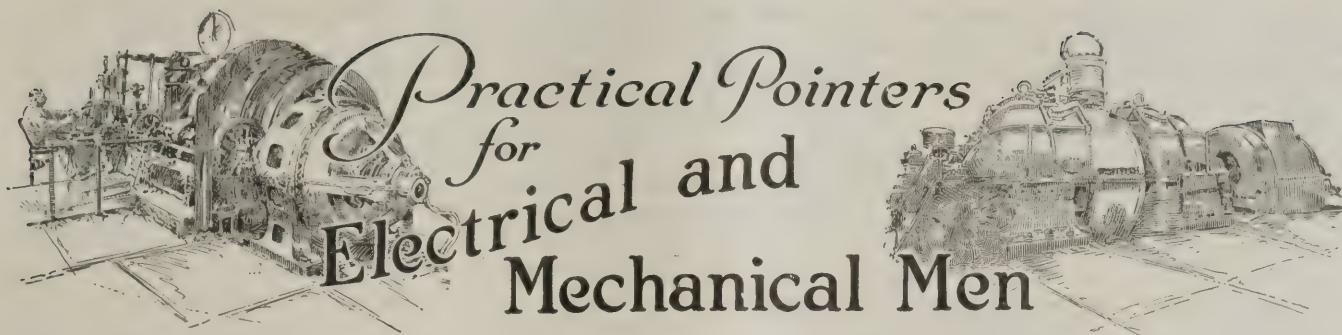

MOTOR-OPERATED BLACKSMITH HAMMER

When labor is short and overhead costs are high, such a device as this hammer works wonderful results and economies.

The striking is very similar to that of a hand swung sledge, the head first rises then strikes its blow and rebounds quickly from the metal. Operations requiring careful work can be performed with greater ease as the blacksmith has control of each blow of the hammer. As a consequence heavy welds, as well as light jobs, can be performed with great rapidity.

The Blacker Engineering Co., Inc., Grand Central Terminal, New York City, is the manufacturer of the complete outfit.

Severe Sparking at Trolley Wheel

WE ARE operating a Baldwin-Westingshouse locomotive rated at 250 volts, and are having trouble with the trolley wheels. Copper appears to burn off the trolley wire and deposit on the trolley wheel; this is accompanied by a constant glow from the wheel and severe sparking. Our track circuit is well bonded and there is no moisture on the wire.

I would appreciate some discussion on this subject from *Coal Age* readers.

New Castle, Ala.

FRANK PARKER,
Mine Foreman.

Sparking at the trolley wheel may be caused by any one or a combination of troubles. The first thing to do would be to investigate the electric circuit. This would consist of a thorough test of the voltage when the locomotive is drawing a heavy current, to determine whether or not the motors are receiving approximately proper voltage, then a test of the return circuit, which although well bonded may be open-circuited at important points.

Series-field troubles exist in many locomotive motors and frequently go unnoticed for years. Short-circuits in the fields can be located by testing as described in the Aug. 9 issue of *Coal Age* and by reading the voltage drop across each coil by means of a voltmeter.

After testing the locomotive equipment, including the motors, controller and resistance, it will then be proper to look at the trolley wheel. The composition of the

metal in the trolley wheel should be such as will resist wear and sparking. Some metals blister and burn whenever an arc is formed upon them. The burned material usually is forced into a flaky mass which packs itself down into the groove of the trolley wheel and thus increases the resistance to the current which is taken from the trolley wire. The increased resistance causes more heating at the wheel and further aggravates the tendency to spark.

Obviously, anything which would prevent the gathering of this burned material would give better contact at the junction of the trolley wheel and wire. This is sometimes accomplished by deepening the groove in the trolley wheel into a narrow V shape, as shown in the cut herewith. This allows the wire to have a wiping action on the side of the groove, thus giving a clean low-resistant contact with the wire.

Court Rules with Reference to Equipment Bought Without Written Warranties

THE question of when and under what circumstances a buyer of machinery will be justified in relying upon the warranties and representations of a salesman as to its condition has been the cause of many lawsuits. And while the question cannot be answered by the statement of a hard and fast rule, because each case of this kind must necessarily be decided in the light of the particular facts involved, yet it may be stated broadly that where such a purchase is reduced to writing the buyer should not rely upon any warranties which have been previously made, unless they also appear in the writing.

This is true because it is an elementary rule of law that prior oral warranties and representations are deemed to have been merged in any subsequent written contract, which precludes the latter from being changed or varied by such prior oral warranties or representations. It follows that where a written order for machinery is given, such order will be deemed to constitute the contract, and as a general rule only the terms as they appear therein may be considered by a court or jury in the event of later dispute.

The application of this rule of law and the danger to the industrial executive in losing sight of it when machinery or equipment is being ordered is illustrated in a most striking and interesting manner in a recent West Virginia court case between a coal company and a Virginia equipment company.

The facts and circumstances out of which the action grew were as follows: The coal company, the plaintiff, purchased from the equipment company, the defendant, a second-hand coal-cutting machine to be used in its mine. This machine was purchased from a traveling

TROLLEY WHEEL WITH DEEP, NARROW GROOVE

These figures show how the high-resistance material packs itself into the groove and how the groove may be shaped to have a wiping action on the trolley-wire contact.

salesman in the employ of the defendant who, it appears, brought the machine to the attention of the plaintiff. The contract of purchase was reduced to writing and provided as follows:

"—— (name of equipment company), —— (name of city), West Virginia. Date July 1, 1921, bill —— (name of coal company), address ——, W. Va., ship to same address, same custom on No. ——, ship freight, when, terms, salesman. —— Type coal-cutting machine, second hand, f.o.b. ——, Alabama, freight allowed, sight draft at \$3,500. Signed —— (name of coal company). ——, Superintendent."

At this point it should be noted that the above contract is in the form of an order, complete within itself in respect to terms and subject matter, though it does not contain any warranty or representations relative to the condition of the machine ordered. The order, as will be noted, simply stipulates for the shipment of one —— type coal-cutting machine; price \$3,500; sight draft attached.

The machine in question was shipped, and received by the plaintiff, who paid the sum of \$3,500 upon its receipt. Upon trial, however, the machine proved unsatisfactory in a number of respects, and a dispute resulted between the plaintiff and the defendant which culminated in the plaintiff instituting a lawsuit in an attempt to recover the purchase price.

In this action the plaintiff, among other things, sought to recover upon the ground that the salesman had warranted the machine as being in a certain condition, and that upon receipt the machine was not as represented. The authority of the salesman to warrant the machine was denied by the defendant, and evidence was introduced to show that the machine was in fact sold subject to inspection and prior sale, and that the defendant had refused to warrant the machine in any way.

In the face of the contention of the plaintiff and the conflicting evidence introduced by the parties the outcome of the case turned upon the question of whether or not the evidence relative to the alleged warranty of the salesman should be received in view of the fact that the negotiations for the machine were subsequently reduced to writing and, as noted above, this writing did not contain any warranties whatever. The case reached the Supreme Court of Appeals of West Virginia on appeal, and in passing upon this point the court decided as follows:

"The authority of the salesman to warrant the condition of the machine is specifically denied. The written order signed by purchaser contains no express warranty of this machine. The only description given is '—— type coal-cutting machine, second-hand.' Can plaintiff ingraft a warranty upon this written order to conform to the statements of the salesman as to the condition of the machine? We think not. . . . If plaintiff had desired, at the time of signing the written order, to have the condition of the machine guaranteed, as represented by the salesman, he should have written the same in the order. . . .

"The contract is complete and unambiguous. . . . This order, stripped of its superfluous verbiage, means that a second-hand coal-cutting machine was to be delivered to the plaintiff f.o.b. Birmingham, Ala., freight to be paid by the equipment company, and a sight draft for \$3,500 was to be attached to the bill of lading, the shipment to be traced and hurried. This, after being accepted by the defendant, constituted the contract, and

contemporaneous oral statements of the salesman cannot be ingrafted upon it. . . ."

In conclusion, after considering other points not material to the subject of this discussion, the higher court affirmed a judgment that had been rendered in the lower court in favor of the defendant, holding, as outlined in the opinion, that the plaintiff was not entitled to recover the money it had paid for the machine, on the strength of oral warranties alleged to have been made by the traveling salesman of the defendant, when such warranties did not appear in the written order as subsequently signed.

The above case was well considered and constitutes a valuable decision on the point decided. It illustrates in a striking manner the importance of having all the terms, warranties and representations relative to the condition of machinery or equipment embodied in the final contract when reduced to writing. Truly, in the light of the facts involved, the above decision becomes one well worth having in mind by every industrial executive when ordering machinery or equipment under circumstances similar to the one in the case reviewed.

LESLIE CHILDS.

Making Whitewashing Easy

AT MANY of our mines there always is a considerable amount of work being done in whitewashing the foot of shafts, barns, pumprooms, and safety holes on planes and slopes. In several places a small hand pump is used to force the liquid from a tank through a nozzle onto the object to be whitewashed. This is a slow and tedious task especially for the man who works the hand pump.

To overcome this difficulty we have built a small truck and mounted on it an unserviceable hot water boiler, or even a large pipe will do. We cut a large hole into the upper side of the boiler, so that the liquid can be poured into it. When the tank is full the cap is screwed back

WHITEWASH TANK WITH AIR PRESSURE CONNECTION

The air pressure forces the whitewash to the hose and nozzle attachment and the work of whitewashing is done both quickly and effectually.

to prevent any whitewash leaking. To one end of the tank is attached a hose connected to an air line; the other end of the boiler has an attachment to the nozzle. When all is ready the air is turned on and regulated by means of a valve attached to the air line. By this arrangement the liquid is forced from the tank through the nozzle by the air pressure. With an air hose and a small auxiliary line on the nozzle a large area can be whitewashed in this way in a very short time.

STUDENT.

IN CONNECTION WITH MINE VENTILATION studies being made at the experimental mine of the Bureau of Mines, Bruceton, Pa., 152 tests recently were made with variations in the velocities and conditions in the airways. Relative velocity heads were determined for timbered entries, entries obstructed with loaded cars, entries obstructed with empty cars, cut-throughs with and without brattices, and for various vanes for conducting air around right-angle turns.

Problems of Operating Men

Working Three Seams of Coal With Rock Partings

Three Letters Suggest Various Methods—
Main Features Maximum Extraction of Coal
and Elimination of Waste Material Handled

REFERRING to the inquiry signed "Presto," which appeared in *Coal Age*, Aug. 9, p. 219, and asked for the best method of working three seams of coal separated by slate and shale partings of considerable thickness, permit me to offer the following:

Summarizing the case presented, we have a hard sandstone roof covering the upper seam, which will average 42 in. of hard splint coal." Below this is a hard sandy shale averaging 60 in. and under that a second seam of coal having an average thickness of 33 in. Then comes another parting of medium hard slate averaging 21 in., beneath which is a soft clean coal 12 in. in thickness.

In all, we have an average of 7 ft. 3 in. of coal, the mining of which will require the handling of 6 ft. 9 in. of rock forming the two partings in these three seams. This is almost a fifty-fifty proposition of coal, and rock and the space left after the coal has been extracted appears to be hardly sufficient for storing the waste material a portion of which would have to be hauled out of the mine.

ESSENTIAL FEATURES SUGGESTS PROPOSED PLAN

In my opinion, to work this as one seam would be a dangerous undertaking for the safety of the workmen, owing to continual falls from the coal face and the sides. While there are doubtless various methods of working these seams, the essential features to be considered are the complete extraction of the coal, as far as that may be practicable, and the elimination of the waste material requiring to be handled.

Briefly explained, my plan would be to develop the bottom and middle seams first. I would adopt the panel system of working, leaving enough pillar to comply with the requirements of the surface conditions, which are not mentioned in the inquiry. These two lower seams will average 45 in. of clean coal, with an average of 21 in. of rock parting, making a total height of 66 in. and affording plenty of room to gob the refuse.

When the work in the two lower seams has been developed sufficiently, I would drive a rock panel up through the 5 ft. of hard sandy shale, on a grade that would afford easy haulage from the top seam. The haulage roads in that seam can be laid out directly over those in the lower seam if that is well timbered; or, as some will prefer, the roads in the top seam can be centered over the pillars in the lower seam.

This plan will eliminate having to blast the hard sandy shale, which in my opinion makes a fine roof

for the working of the two lower seams. Besides eliminating the necessity of handling this 5 ft. of rock, the plan insures that the top coal will be absolutely clean if proper care is taken in its mining.

As quickly as a panel is finished in the top seam, the work of extracting the pillars in that seam can be started and when that is well under way similar work in the lower seam can be undertaken. It is my belief that, by this means, it will be possible to get out most all of the coal and leave the refuse in the mine.

Clinton, Ind.

W. W. H.

MY PLAN of working the three seams under discussion in *Coal Age*, while having in view a maximum percentage of production per man per day and economy of working, would be to follow somewhat the outline given by the inquirer, in the issue, Aug. 9, p. 219, though differing from this method in certain details.

Starting in the combined bottom and middle seam, I would drive an entry and air-course on the double entry system, turning rooms on 90-ft. centers to the right and left of the main heading. These rooms should be opened out to a width of 40 ft., leaving 50-ft. pillars of coal between them. I would lay single tracks on the entry and air-course and double tracks in all rooms.

All entries and rooms should be driven to the boundary, or to the meeting point, taking out all the coal in the two lower seams and stowing the waste material of the parting between the two tracks in each room. When the entries have reached the boundary line and the rooms worked to the limit on each side, my plan would be to start the work of retreating, by dropping the shale parting and taking down the top coal, lifting the track as the work proceeds. The coal can be loaded off the shale just as it falls. In doing this, it will be unnecessary to handle or break up the parting material, which will save much work that would otherwise be required.

Then, when the work has been carried back to the entry, I would split the 60-ft. pillars separating the several rooms, by driving a 30-ft. room in each pillar. As these rooms reach their limit, I would follow the same plan in retreating, taking down the top coal and loading it off the shale where it has fallen.

The two 10-ft. pillars remaining in each case can then be abandoned, as their extraction would be too dangerous and difficult to undertake and the value of the coal lost would not warrant the risk.

A. G. BUCHANAN.

Flattop, Ala.

THE plan of working three seams of coal separated by thick partings, as suggested in the inquiry signed "Presto," *Coal Age*, Aug. 9, p. 219, does not appeal to me as feasible. He suggests keeping the workings in the two lower seams a little ahead and then dropping the hard sandy shale to get the top coal. Not only is there too much stone to handle in this manner,

but there are too many hazards in the undertaking and when the whole weight comes on it would be difficult to control.

It is my belief that the best way to get out this coal is to handle the three seams as two distinct propositions. In my opinion, the top seam should be worked out on the advancing longwall plan. When the main entries have been driven far enough from the shaft or the slope, cross-entries should be turned to the right and left while keeping the main entries going.

When the main roads have reached a point, say 100 ft. beyond where the cross-roads were turned, the former should be widened into a "mothergate." This should be driven forward at a width of 10 or 12 yd. At the same time, cross-headings should be started to the right and the left, driving these 10 yd. in width. Tracks should be laid in the center of each opening.

GENERAL PLAN OF LONGWALL WORK

As in all longwall work, the top should be brushed on the roads and the waste material used for packs to support the roof. On the cross-headings, gateways should be turned every 10 yd. and driven parallel to the mothergate. In this plan, the mothergate will be making a loose end for each breast. This will continue for ten gateways on either side of the mothergate. At this distance, 100 yd., a chute should be driven back across 100 ft. of solid coal to reach the cross-headings previously mentioned. When this has been done, the coal beyond can be taken out through this chute and the old road abandoned. Also, new cross-headings should be started from the mothergate at intervals of 60 yd. and driven right and left, each cross-heading cutting off the gateway below as it advances.

As development proceeds, the chute just mentioned should be extended to meet the next pair of cross-roads driven from the mothergate. If this plan is followed, it will permit all of the coal to be taken out in the top seam. In the meantime, the middle seam can be worked out, taking the bottom seam along with it on the "bord-and-wall" or room-and-pillar system. In my opinion, that method is better than the block longwall or long-wall panel system. The partings of medium soft slate varying from 18 to 24 in. will form good material for stowing in the bords as waste. I believe the hard sandy shale varying from 48 to 72 in. in thickness will make a good roof in working the lower seam and the plan will be far less dangerous than to attempt to work the three seams as a single proposition.

Neffs, Ohio.

PICKS.

Novel Plan of Wetting Bug Dust

Application of water to cutterbar on machine—Plan approved by Mine Inspectors Institute—Scheme requires machine sent to shop for cutting groove.

WHEN reading the report of the last annual convention of the Mine Inspectors Institute of America, held at Pittsburg, Kans., *Coal Age*, July 19, p. 113, and continued on page 149 of the following issue, I was pleased to note the remarks of Frank Hillman, safety engineer, Woodward Coal & Coke Co., regarding the application of water to the cutterheads of the mining machines, in the mines of the T. C. I. & R.R. Co.

The scheme, as briefly described by Mr. Hillman, would seem to be more simple of application than is actually the fact. He states that the plan is to loosen

the plate on the cutterbar of a mining machine and lay, in the groove therein, a half-inch pipe by which water is conveyed to the cutting teeth. When the machine is running the water mixes with the fine dust, converting it into mud and rendering it harmless.

ROTARY DUMPS INSTALLED UNDERGROUND

As a safety measure, the plan is certainly a great success. It was originally intended to eliminate the dust trouble that grew out of the installation of rotary dumps, by that company, on their shaft and slope bottoms. The coal is dumped from the mine cars into hoppers and loaded into skips for hoisting.

These dumps being situated on the main intake air-ways, large quantities of dust were previously carried into the mine on the air current when the cars were being dumped. Some of the dumps are operated by electric motors, which increase the danger from the possible arcing of the current in the presence of the dust-laden atmosphere. By the adoption of the scheme of applying water to the cutterbars of the machines the dust problem is practically solved.

It is well known that the use of mining machines creates a dangerous percentage of dust, which is thrown into suspension in the air at the working faces. The result is that a dust explosion is liable to be caused, at any moment, by the blowing of a fuse or the sparking of the motor. Attempting to eliminate the danger by spraying has not proved satisfactory.

MINE INSPECTORS APPROVE THE PLAN

It is gratifying to note that the convention of mine inspectors mentioned went on record by a resolution approving the plan of applying water to the cutterheads of mining machines when in operation. It is only fair, however, to explain that the adoption of the plan is not as easy as may be supposed. It will be found that the removal of the top plate is quite a serious matter, as it involves taking out sixty-five half-inch rivets and three $\frac{3}{4}$ -in. rivets, in the shop on the surface.

Moreover, when the plate has been removed, there is no groove in which to lay the half-inch pipe, and it is necessary to cut a slot from 5 to 7 ft. in length, in a slotting machine. Comparatively few mines have machine shops suitably equipped for doing this class of work and only those companies who are safety enthusiasts will undertake the job of remodeling their machines in the manner described.

In my opinion, what the T. C. I. & R.R. Co., has accomplished in this respect has solved the problem for all machine mines. I believe the scheme they have evolved will prove a valuable help in bringing such mines close to being 100 per cent dust proof, particularly if the further precaution is taken of spraying the coal after shooting. My observation is that much fine dust covers the coal shot down and, unless spraying is done after shooting, this dust is distributed on the roads.

A brief outline of the work of remodeling a machine for the purpose of applying water at the cutterhead in the manner mentioned will no doubt be of interest. As stated, the top plate is removed by taking out the sixty-eight rivets and the bar sent to the slotting machine. A groove is cut in the bar, starting 3 in. in front of the gear housing and making a turn of 45 deg. inward when reaching a point about 9 in. from the sprocket wheel, between the left and right sidebars.

In this slot, a copper pipe is laid allowing the end of the pipe to extend 6 in. beyond the end of the groove.

This 6-in. extension is made to run parallel to the right-hand sidebar and made to point toward the kerf, so that the water flowing from the pipe under pressure will play on the teeth of the sprocket wheel and be carried by it and its own pressure to the cutting bits in contact with the coal.

At the other end, a hole is drilled in the top plate and a short nipple inserted, which is attached to the copper pipe beneath. To this nipple is connected a half-inch pipe, having a 1-in. strainer and a stop valve. This half-inch pipe is carried along the side of the gear housing to which it is attached by metal straps. The connection between the pipe and the nipple on the cutterbar is made by rubber tubing, which with the piping is protected from injury by an auxiliary housing of sheet steel bolted to the gear housing with spacers between.

The water is supplied from the regular spraying system, which is kept close up to the face of all working

places. The system consists of 4-in. pipe on the main entries, 1½-in. pipe on the cross-entries and ½-in. pipe in the rooms. The water is that discharged from a pump under a pressure head of 250 ft. Each machine runner is supplied with 50 ft. of hose to connect his machine with the spraying line. This length of hose enables the machine to cut rooms 35 ft. in width.

The closest supervision is maintained by the company over all its workmen. The firebosses make two visits a day to each working place. They and other officials are instructed to observe the condition of the machine cuttings and report if any are found dry. Each machine runner is instructed to consider his machine out of commission if, for any reason, the water fails to pass through the pipe with sufficient pressure and in quantity to keep the bug dust thoroughly wet when cutting. Instant dismissal is the penalty for failure to comply with instructions.

Inquiries Of General Interest

Ignition of Gas by Sparks from Falling Rock Possible

Hard Siliceous Roof Rock Falling Emits
Sparks of Great Intensity—Cause of Bellevue Mine Explosion and Other Disasters

WE ARE anxious to obtain reliable information in regard to the possible ignition of gas by sparks that may be struck by pieces of rock falling from a hard sandstone roof in a mine. Assume a drift mine opened in a 5-ft. coal seam and developed to an extent such that there is a large robbed-out area covering approximately 660,000 sq.ft. Again, suppose a general fall of roof occurs in this area some distance back from the edge of the pillars, which are being drawn.

We will say there is a small amount of inflammable gas hanging in the roof of this section from which the coal has been mined. Is it reasonable to suppose that this gas can be ignited by sparks struck by rock falling from the roof? Or, is it possible for the fall of the rock to stir up a cloud of dust that could be ignited by the same spark? Any information that will make clear the possibility of such an occurrence will be much appreciated.

G. R. LUKE, General Foreman,
Benham, Ky. Wisconsin Coal Co.

As early as 1896, when an explosion occurred in the Maindy Pit, Glamorgan County, South Wales, the disaster was attributed to sparks struck by rock falling from the roof in an abandoned area of the mine. It was well known that gas was present, it being difficult to keep the place free from such accumulations. At that time and since when a mysterious explosion has taken place and the suggestion made that the ignition was caused by sparks struck by flinty rock falling from the roof, it has always been met with expressions of doubt and even ridicule.

In the explosion at the Maindy Pit, Nov. 8, 1896, a

practical test was made to prove that the assumed cause of the disaster was not only possible but probable, no other source of ignition being known to be present in the mine at the time. By way of experiment, a box measuring about 3 ft. on the cube was equipped with a rotating spindle to which pieces of the rock in question were attached. Similar pieces of the same rock were fastened to the sides of the box in a manner to be struck by the rock attached to the spindle. The box was then filled with an explosive mixture of gas and air and a violent explosion followed when the spindle was rotated. The same experiment was repeated with the box filled with an atmosphere of dust-laden air, no gas being present. The fact that no explosion followed in this case suggested that the sparks struck by the rock were not of sufficient intensity or volume to ignite the dust-laden air in the absence of gas.

Another instance in which the cause of the explosion has been attributed to the ignition of gas by sparks struck by rock falling from the roof is that of the Bellevue mine explosion, which occurred Dec. 9, 1910, when 37 out of 47 men, who were in the mine at the time, lost their lives. The Bellevue mine is one of a group of three mines worked by the West Canadian Collieries Co., Alberta, Canada. A series of explosions had occurred in this mine from seemingly mysterious causes, within three months of each other. In the first explosion, Oct. 31, 1910, and in the third explosion, Jan. 28, 1911, there was no one in the mine at the time. An

account of this explosion is found in *Coal Age*, Vol. 2, p. 457. The seam consists of 13 ft. 2 in. of coal containing three 1-in. bands of bone coal and dirt. The coal is underlaid with a hard floor, while the roof is a hard siliceous sandstone, the accompanying illustration at the left being a microscopic section of the rock.

MICROSCOPIC SECTION
OF ROCK

When a specimen of this roof rock is struck a glancing blow with a hammer, the portion struck will glow red hot, for an instant, in the dark. An analysis shows that the rock contains some bituminous matter, the apparent combustion of which would account for the observed glow when the rock was struck, sufficient heat being generated by the blow to cause the ignition of the bituminous matter.

or the gas generated from it, when the hammer fell. Two pieces of the rock when struck together caused sparks to fly from the contact. A piece of the rock held against a steel flint mill produced a shower of sparks.

According to the statement of miners engaged in drawing pillars in the Bellevue mine, when a cave occurred the glow of the sparks from the falling rock would light up the place and make the timbers visible, the miners' lights having been extinguished by the rush of air from the fall. These facts and the experiences of the men who worked in the mine leave not

the shadow of a doubt regarding the source of the ignition of the gas.

Safety when working under such conditions must depend on the thorough ventilation of the working places to keep them free from accumulations of gas, and the adoption of a method of working that will reduce to a minimum the liability of heavy falls of roof. The report on this explosion, as made by Mine Inspector, John T. Sterling and Professor John Cadman, of the University of Birmingham, England, is found in the Transactions of the Institute of Mining Engineers, Vol. 44, p. 740.

Examination Questions Answered

Miscellaneous Questions

(Answered by Request)

QUESTION—In a mine where 50,000 cu.ft. of air per min. is furnished, in which 3 per cent of gas was detected, what was the total flow of gas per minute?

ANSWER—Assuming that the given volume (50,000 cu.ft. per min.) is measured on the return airway and includes both air and gas, as the question seems to imply, the gas forming 3 per cent of this volume, the quantity of gas generated is $0.03 \times 50,000 = 1,500$ cu.ft. per min.

QUESTION—A counter-gangway is 1,680 ft. long, on a pitch of 10 deg.; what will be the horizontal distance measured on the mine map?

ANSWER—The corresponding horizontal length of the gangway is $1,680 \times \cos 10 \text{ deg.} = 1,680 \times 0.9848 = 1,654.46$ ft. Since the law requires (Art. 3, Sec. 1) that the mine map be drawn to a scale of 100 ft. to the inch, the measurement on the map would be 16.54 in.

QUESTION—What is a regulator as applied to mine ventilation?

ANSWER—In mine ventilation, a regulator is any means employed to divide the air current proportion-

TWO FORMS OF MINE REGULATORS

ately between two or more splits. The most common form of regulator is a brattice or partition erected in the airway and having an opening the size of which can be adjusted by a movable shutter to meet the desired requirements. This form is known as the box regulator and is located on the back entry near the end of the split where it will not obstruct haulage operations. Another form is a door regulator in which a door is erected at the entrance of a split and swung to one side or the other of the passageway so as to control the quantity of air entering the split in any desired proportion. These two forms of regulators are shown in the accompanying figure.

QUESTION—If the horsepower of a fan is 40 and the water gage 1.75 in.; what quantity of air would you expect to obtain, supposing the useful effect of the fan to be 50 per cent?

ANSWER—If the fan develops 40 hp. having an efficiency of 50 per cent, the power on the air is $0.50(40 \times 33,000) = 660,000$ ft.-lb. per min. Then, since a water gage of 1.75 in. corresponds to a pressure of $1.75 \times 5.2 = 9.1$ lb. per sq.ft., the quantity of air produced by this fan is $660,000 \div 9.1 = 72,527$ cu.ft. per min.

QUESTION—What horsepower will give a current of 60,000 cu.ft. per min., in a mine having four splits, each split being 6 x 8 ft., in section, and 5,000 ft. long?

ANSWER—The quantity of air passing in each split is $60,000 \div 4 = 15,000$ cu.ft. per min. The rubbing surface in each split is $2(6 + 8)5,000 = 140,000$ sq.ft., and the sectional area $6 \times 8 = 48$ sq.ft. The pressure required to pass 15,000 cu.ft. per min. in each split is,

$$p = \frac{0.00000002 \times 140,000 \times 15,000^2}{48^3} = 5.7 \text{ lb. per sq.ft.}$$

The horsepower then required to circulate a total of 60,000 cu.ft. of air per min., in four splits against this pressure is,

$$H = (60,000 \times 5.7) \div 33,000 = 10.36 \text{ hp.}$$

QUESTION—What quantity of air would be required for the following organization: Coal loaders, 310; motormen, 22; trackmen, 8; general foreman, 1; assistant foremen, 6; pumpers, 4; electricians, 3; company men, 75? Show the solution.

ANSWER—The Alabama Mining Law (Sec. 40) requires the circulation of 100 cu.ft. of air per minute. for each person employed in the mines, and 500 cu.ft. per min., for each mule. In this case, there is a total of 429 persons, and it may be assumed that the coal is all gathered and hauled by motors and no mules are employed underground. In the absence of any special conditions regarding gas and dust that would require a larger quantity of air, the volume necessary to comply with the mine law is $100 \times 429 = 42,900$ cu.ft. per min. A fair estimate would place the circulation required in this mine at, say 45,000 cu.ft. per min.

QUESTION—What kind of a system of shotfiring would you recommend, in a gaseous mine where electric cap lamps are used?

ANSWER—Shotfiring, in such a mine, should be performed by competent shotfirers appointed for that purpose, the work to be done after all the men have left the mine except the shotfirers. The safest plan is to have all holes drilled by the miners examined, charged and fired by the shotfirers, using permissible powders, and examining every place for gas before firing a shot therein. No miner should be permitted to fire a shot or have in his possession materials for that purpose.

Testimony Completed in Assigned-Car Rehearing; Oral Argument Set for Dec. 17-19

Virginian Official Stresses Need of New Coal Branch—
Demurrage Ruling Issued—Carriers Reject Plea to Cut
Wheat Rates—Anthracite Rate Hearings On in East

After ten days devoted to the taking of testimony, the Interstate Commerce Commission on Nov. 1 closed its rehearing of the assigned car case. The dates for oral argument have been set for Dec. 17, 18 and 19. Briefs are to be filed by Dec. 1.

A rumor is in circulation that the effective date of the order is to be deferred until April 1. So far as can be learned, there is no basis for such a report. It is evident, however, that there will be some delay, since Commissioner Aitchison announces that he must undergo a surgical operation which he expects will keep him away from his desk for three weeks.

It had been taken for granted until recently that the private-car interests would carry the case to the U. S. Supreme Court, were the ultimate finding in the case not to their liking. Grave doubt now is expressed as to whether or not this question is justiciable. As the question involved appears to be one of regulation, only, some are of the opinion that it is not a matter which the federal courts will entertain.

MUCH OPPOSITION TO ASSIGNED CARS

Almost the whole of the last day of the hearing was taken up by witnesses opposed to assigned cars of all classes. Among those who testified in opposition to assigned cars, filing exhibits intended to show that discrimination was shown as between mines loading assigned cars and those loading unassigned cars, were Charles O'Neill, secretary of the Central Pennsylvania Coal Producers Association; C. D. Boyd, traffic manager of the Hazard and Harlan Coal Associations; W. L. Hammond, vice-president, White Star Mining Co.; John Marland, general superintendent of the King Harlan Coal Co.; H. B. Tyree, fuel agent, Detroit Edison Co.; W. D. Ord, president, Empire Coal & Coke Co.; T. F. Farrell, vice-president, Pocahontas Fuel Co.; A. R. Yarborough, traffic manager, Kanawha Coal Operators Association, and S. C. Higgins, secretary, New River Coal Operators Association. Mr. Hammond's company is a subsidiary of the Detroit Gas Co. and Mr. Marland's company a subsidiary of the Detroit Edison Co. W. D. McKinney, secretary of the Southern Ohio Coal Exchange, had offered exhibits and testimony along the same lines Oct. 30.

John D. Battle, traffic manager of the National Coal Association, testified briefly on behalf of the association in connection with the railroad-fuel assigned car, confining his remarks to the present railway situation as reflected in the progress reports released by the American Railway Association, and a number of tables were filed with the Commission indicating that for several years past non-coal producing roads either do not own a sufficient number of cars to protect the tonnage that actually moves on their rails, or coal cars moving to the rails of non-producing roads are not returned promptly. Figures were filed showing the large number of cars on line compared with ownership.

Charles M. Schwab, chairman of the board, Bethlehem Steel Corporation, stated that his companies resorted to the purchase of privately owned coal cars only after all of the methods had failed to get a regular and suitable supply of coal. James A. Campbell, president of the Youngstown Sheet & Tube Co., followed Mr. Schwab with practically the same kind of testimony. Both agreed that private cars, as an investment, is not a good one but that they are necessary in order to operate their plants successfully. Robert Hobson, president of the Steel Co. of Canada, and Harry Colby, a member of the firm of Pickands-Mather Co., testified along the same lines as did Messrs. Schwab and Campbell. L. H. Bihler, on behalf of the United States Steel

Corporation and its subsidiary companies, testified to the effect that without the use of private cars they had experienced great difficulty in getting their fuel.

A witness for the Pittsburgh Plate Glass Co. said that he did not desire any preferential movement or service from the carriers during a shortage of transportation facilities other than cars. Edward J. Berwind, testifying on behalf of the Berwind-White Coal Co., made the same declaration and put considerable evidence in the record as to the displacement of coal by fuel oil in the East, stating that his company alone, this year, estimates its loss at 1,200,000 tons of coal to fuel-oil competition. Many witnesses testified that they had not been able, in the past, to get a suitable supply of coal regularly until they acquired their own cars.

One of the strong witnesses of the concluding sessions of the rehearing was Van A. Bittner, who appeared as the personal representative of John L. Lewis, president of the United Mine Workers. Mr. Bittner told the Commission that the United Mine Workers is squarely opposed to assigned cars. "While assigned cars secure an ideal condition for a small minority of coal miners at particular mines," said Mr. Bittner in the course of his testimony, "it creates an altogether different condition at the majority of mines where the majority of the men work." Evidence had been submitted previously to show that the labor turnover was much greater at comparable mines when one was served with assigned cars.

Mr. Bittner laid at the door of the assigned car no small measure of the responsibility for the overexpansion of coal mining. If the practice is abolished, he predicted that only a short time will be required to drive out of business the uneconomical mine. If only the more efficient mines live, it will do much toward stabilizing the industry, he said.

A new point was made by one witness who contended that coal for household consumption should have first call on cars if the practice is to be continued. A spokesman for the Associated Industries of Massachusetts urged that nothing be done which would interfere with the right of the railroads to use their own cars as they see fit and that nothing be done to add to the price which the railroads will have to pay for their fuel. Abner Kunsford, operating the mines of the Fordson Coal Co., in eastern Kentucky, admitted that it doubled the cost of production when assigned cars are not available.

Hix Says Virginian Ry. Will Dry Up Unless It Can Build New Coal Branch

Testifying before Director Mehaffie, of the Bureau of Finance of the Interstate Commerce Commission, at Washington, Oct. 31, C. H. Hix, vice-president of the Virginian Ry., said that unless the road was permitted to develop fully its resources in the bituminous coal fields it would dry up for lack of business.

The hearing was on the Virginian's and Pocahontas Fuel Co.'s petitions for reconsideration by the commission of the order denying the Virginian authority to extend its lines a little more than one mile in Wyoming County, W. Va., to coal fields owned by the Pocahontas Fuel Co. The commission held the Virginian had not been able to furnish the number of cars ordered by the coal mines already opened and dependent on it in whole or in part for car supply.

This conclusion reached by the commission was emphatically denied by Vice-President Hix, who asserted that, with

the exception of the period from July, 1922, to June, 1923, inclusive, when abnormal conditions existed on account of the strikes of bituminous-coal miners and railway shopmen, the Virginian had adequately met the demands on it for service and at various times and for considerable periods had had a surplus of empty coal cars.

Declaring the company in 1922 had over 8,000 coal cars, Mr. Hix said, in April this year 1,500 additional cars were ordered, 1,000 of which will be of 120 tons capacity and 500 of 70 tons capacity. He said the company had 123 freight locomotives in 1922, and had acquired this year fifteen heavyallet locomotives.

The Virginian has increased its coal handling facilities at Sewalls Point at a cost of \$3,250,000 and has contracted for the electrification of 134 miles of its line at a cost of \$13,000,000, Mr. Hix said. These improvements will greatly increase the company's facilities for handling increased coal shipments, the witness said.

Railroads Refuse to Reduce Wheat Rates: No Decision on Coal Tariffs

The Committee of Railroad Executives appointed at the conference in New York on Oct. 30, consisting of Samuel Rea, president of the Pennsylvania; Howard Elliott, chairman of the Northern Pacific; J. E. Gorman, president of the Rock Island; W. H. Finley, president of the Chicago & Northwestern, and H. E. Byram, president of the Chicago, Milwaukee & St. Paul, notified the Interstate Commerce Commission Nov. 1 that they declined to accede to the request of President Coolidge that the carriers voluntarily reduce rates on wheat for export.

Nothing was given out about coal rates, but it was unofficially said the roads are adverse to changing the differential between export and domestic coal rates.

The American Farm Bureau Federation takes exception to the decision of the railroad men, and insists that the Commerce Commission cut wheat rates. The American Mining Congress has filed with the Commission a request that if wheat rates are to be examined, rates on all basic commodities be included in the study.

Retail Coal Prices Unaffected by Freight Rates, Vermont Dealers Testify

The people of Massachusetts want no charity, but they want absolute assurance that the factors entering into the final cost of coal are equitably assessed, including the railroad rate, said Representative Henry L. Shattuck, of the Massachusetts Coal Commission, testifying Nov. 2 at Boston before Chief Examiner Butler, of the Interstate Commerce Commission, who is investigating rates on anthracite on Eastern railroads.

Eugene Hultman, Fuel Administrator, suggested that the rate from the mine to tidewater might be lowered and that a large proportion of the coal coming to eastern Massachusetts might be brought by water, 32 per cent being so transported at the present time. He called attention to the disparity in rates, saying the rate to Montreal, a distance of 405 miles, is \$4.96 per gross ton on the Delaware & Hudson, the largest coal carrier to New England, while the rate to Lawrence, Mass., 378 miles, is \$5.04.

H. A. Taylor, counsel for the Eastern group of roads, urged that the roads should not be asked to stand any reduction on coal rates, saying that since key rates were established by the commission in 1916 the net increase in coal rates to Boston has been only 5.7 per cent, while on other commodities the increase has been 81 per cent. Meanwhile, he said, freight operating expenses of the Eastern rate group have increased 117 per cent per 1,000 net ton miles from 1916 to 1922.

Taxes have increased since 1916 more than 89 per cent and wages have gone up per man 118 per cent since 1915, exclusive of increases due to punitive overtime rates of pay, said Mr. Taylor. Many materials have increased in the same period over 100 per cent.

Representatives of the New Haven and the Boston & Maine supported Mr. Taylor's contention.

The 10-per cent freight-rate reduction on anthracite of July, 1922, had no effect on the retail price, according to the testimony of every retail dealer but one called as witnesses at the inquiry held at Montpelier, Vt., Oct. 31, by the Interstate Commerce Commission. H. M. Odell, of Montpelier, Vt., said that his company had given the public the benefit of the reduction. F. L. Platka, of Burlington, stated that his company, the E. S. Adsit Coal Co., received only \$4.31 per ton for its anthracite after deducting from the retail price of \$16.50 the cost of the coal at the mine and the freight charges.

Former State Fuel Administrator H. J. M. Jones declared that the root of the evil in the coal situation lay in the prices charged by independent operators, which ranged from \$18 to \$20 per ton as against \$15 charged by the "old line" producers.

Hearings were to be held in Albany, N. Y., Nov. 5 and 6; Rochester, Nov. 7, and in New York City, Nov. 9.

I. C. C. Examiner Rules on Demurrage

Reporting in the case of the Tidewater Coal Exchange vs. the Baltimore & Ohio R.R., Interstate Commerce Commission Examiner Butler rules that:

Demurrage assessed against complainants during eighteen months under the average plan and monthly settlements made without objection or request for any other plan for assessing demurrage where many thousands of cars were handled on a basis of five days per car free time, are not entitled to have demurrage charges reassessed under straight demurrage, because no average demurrage agreement was signed by them. Demurrage charges on cars at tidewater detained loaded with bituminous coal is unreasonable to the extent that the cars were not unloaded in the order of their arrival or substitution of time of detention allowed on accruals during the monthly periods for settlement. Reparation awarded.

Where a demurrage tariff provides that cars shall be released from demurrage at the time the vessel registers for the cargo, of which the coal dumped into the vessel is a part, the shipper is not entitled to have cars released from demurrage at the time the vessel registers unless he is in a position to accept delivery of the coal.

Under the tidewater coal demurrage tariffs, which provide for an average of five days per car free time, shippers are entitled to have excess credits for free time accumulated during a calendar month applied to the cancellation of debits for demurrage accruing during the same month on cars that remained unreleased at the end of such month.

Southern Illinois Men Talk of Shipping Coal by Water

A few of the coal operators in southern Illinois are working hard for water transportation of coal out of Franklin County to the Mississippi by way of the Big Muddy River. They made their appearance again during the late October hearings held in the Middle West by the Senate committee that is gathering information on the Great Lakes-to-the-Gulf project covered in the McCormick 9-ft. channel bill now before Congress. Joseph Leiter, lessor of the Zeigler coal properties operated by Bell & Zoller, is a leader in the Big Muddy movement.

He and State Senator Sneed, of Herrin, and various citizens of Franklin County said it would cost \$4,280,000 to dredge the Big Muddy and build docks to handle several million tons of southern Illinois coal output to the Mississippi. The Big Muddy project is not now included in the McCormick bill for the Great Lakes-to-the-Gulf development. They argued that the expenditure is justified as a freight-rate reducing measure and because the country's future need for coal demands a better outlet from southern Illinois than merely railroads.

C. F. Richardson, of Sturgis, Ky., head of the West Kentucky Coal Co., said that coal from his region can be shipped to Chicago by water cheaper than by rail, and he spoke after long experience in barging coal on the Ohio and Mississippi.

Strikes Menace Hard-Coal Output

Succession of Walkouts Emanate from Trivial Grievances—Hudson Trouble Scarcely Settled When 10,000 Pennsylvania Coal Co. Miners Quit.

The strike menace in the anthracite field is looming as the hard-coal operator's greatest problem in the effort to bring production to higher levels. This has been especially true since the signing of the new wage agreement and is causing no little consternation among anthracite producers. In a recent statement the Anthracite Operators General Committee declared that twenty strikes, involving 30,000 men, had occurred in the anthracite mines since the 10-per cent wage increase settlement through Governor Pinchot, and a loss of 125,000 tons in production had been the result. This statement covered a period of but one month. Since that time about a dozen more strikes have taken place.

In most cases the strikes originate from trifling grievances concerning one or two of the workers. A colliery is laid idle due to hasty action of the grievance committee and the committee's apparent belief that a strike is the remedy for all ills. The coal companies are solid in their policy to discuss no grievances while the men are idle, and after a few days of idleness the workers usually return to their posts. In the meantime thousands of tons of anthracite are lost to the market and thousands of dollars in wages are lost to the men.

GRIEVANCE COMMITTEES DISREGARD UNION OFFICIALS

An instance of the manner in which the general grievance committees dominate the workers and utterly disregard the wishes or apparent wishes of the officials of the United Mine Workers was made plain in the recent general strike of Hudson Coal Co. mine workers in Lackawanna and Luzerne counties. At a meeting of the general grievance committee several local union representatives of the Hudson collieries reported grievances. At the meeting officials of the district union requested the committee to have the grievances taken up through the regular channels and if necessary have the board of conciliation pass upon their merits. This was agreed to after some argument. A week later, however, with no district union officials present, the grievance committee met again and declared a general strike effective at once. Eighteen of the Hudson company's twenty-two collieries were thrown idle. The strike continued for three days.

After it had become plain that the company officials would not negotiate while the operations were idle, the committee called a meeting and declared the strike at an end. The strike was a costly one to the anthracite market and to the miners. Over 60,000 tons of coal was left unmined and the pay envelopes of the workers were short by thousands of dollars.

At the end of the short period of two weeks following the conclusion of the Hudson general strike, the general grievance committee of the Pennsylvania Coal Co. unions in the Pittston field met and declared a similar unsanctioned general strike. In answer to the strike call about 10,000 miners left work Thursday, Nov. 1, and nine operations were made idle.

At a meeting lasting six hours the grievance committee of the Pennsylvania Coal Co. voted Nov. 2 to call off the strike and send the men back to work Monday, Nov. 5. President Cappellini addressed the meeting, urging the men to return to the mines and scoring men who worked only a few hours a day.

In the latest general walkout evidence of a new angle was presented in the conflict within the ranks of the mine workers, and to those familiar with the situation the impression is that the strike was called more in defiance of the present union officials of District 1 than for a settlement of grievances. The coal company and the consuming public were the "goats." It is true, however, that many grievances have been reported by the general grievance committee and action in their settlement has been slow.

The apparent split within the ranks of the miners' union

was occasioned by the action of Rina'do Cappellini, president of District 1, in overlooking the Pennsylvania Coal Co. union leaders when recommending the appointment of four new organizers for the district. It was the Pennsylvania company men who placed Cappellini in the field for president this year. He was supported heartily throughout the Pittston region and received his majority from that section of the district.

When the meeting of the general grievance committee of the Pennsylvania unions was called to consider grievances and threats of a strike were heard, Cappellini appointed his vice-president, George Isaacs, to attend the meeting and express the views of the district officials on the general strike question. Isaacs attended the session and voiced the opposition of the district officials to general and unsanctioned strikes. He was not received very warmly and his advice was ignored.

The labor situation in the anthracite field has assumed a volcanic aspect. Strike eruptions have been frequent. Hardly a week goes by without three or four petty strikes breaking out, existing for a few days and subsiding. In every case the walkouts are not sanctioned by the district union officials, but nevertheless they have their effect on the coal market, the comfort of the consumers and the miners' pocketbooks.

Wadleigh Resigns as Coal Division Chief

Francis R. Wadleigh, Chief of the Coal Division of the Bureau of Foreign and Domestic Commerce and former Federal Fuel Distributor, tendered his resignation to Secretary Hoover Nov. 2 on account of "the necessity of returning to private commercial life." He will associate himself with the C. E. Tuttle interests.

Mr. Wadleigh's retirement from the commercial intelligence service of the government is another instance of the unfortunate effects of salary limitations and other restrictions in a field of government activity which is feeling most directly the competition of the business world in its demand for the services of high-grade commercial experts, according to Director Klein of the Bureau of Foreign and Domestic Commerce.

Mr. Wadleigh was appointed head of the Coal Section of the Bureau of Foreign and Domestic Commerce in October, 1921. During the coal miners' strike in 1922 he acted as assistant to Secretary Hoover on all matters pertaining to coal and was a member unofficially of the President's Coal Committee. In September, 1922, Mr. Wadleigh was appointed assistant to the newly created Federal Fuel Distributor, C. E. Spens, and on the latter's resignation, Jan. 1, 1923, was appointed Federal Fuel Distributor. Upon expiration of this office by limitation of law, September, 1923, Mr. Wadleigh resumed duties as chief of the Coal Division of the Bureau of Foreign and Domestic Commerce.

Dr. Klein and other officials of the Bureau of Foreign and Domestic Commerce expressed the highest appreciation of Mr. Wadleigh's work as chief of the Coal Division and stated that "the resignation was accepted with keen regret."

Dr. Edward T. Devine has written to *Coal Age* calling attention to an error in an editorial published in the issue of Oct. 4, page 504, on "What Do Miners Earn?" The statement was made that "to a subcommittee, Commissioners Neill and Devine, were assigned the studies of labor, including that of earnings." Dr. Devine calls attention to the fact that it was Judge Alschuler who was appointed to this subcommittee with Dr. Neill. It was so reported in *Coal Age* of Nov. 30, 1922, page 887, and the reference in the issue of Oct. 4, is an error. Dr. Devine adds "You misstate the facts again when you say that the only credit that attaches to the Commission is for selecting highly competent people to do the work, a purely technical and highly complicated job. I share your high estimate of the credit which should be given to the statistical experts who made the study of earnings; but Miss Bezanson and her associates would tell you that Commissioner Neill deserves personal credit for a very active part in planning and carrying through this technical and complicated job."

Need of Dictator in Coal Industry Again Emphasized

Pittsburgh Coal Producers Association Resigns from National—Move May Prove Significant When Congress Takes Up Coal Legislation

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

That the coal industry needs a dictator has been emphasized again by the action of the Pittsburgh Coal Producers' Association in tendering its resignation from the National Coal Association. Incidentally the resignation has not been acted upon. The difficulty may be ironed out. At any rate the National's revenues will not be affected, since practically all of the companies making up the Pittsburgh Association are taking out individual memberships in the National. Nevertheless, the incident is regarded here as one of much significance. The legislation which will be enacted at this session of Congress will depend to a great extent on the conduct of the coal industry during the period between the issuance of the reports of the Harding Coal Commission and the time when coal legislation will be brought on to the floor of the Senate or the House of Representatives.

If those who favor federal regulation of the industry can point to the fact that the industry is even incapable of maintaining a representative national association, they would have evidence to substantiate their contention that there is not enough unity among the producers to make probable any constructive accomplishments within the industry to make it function better.

COAL INDUSTRY'S CHANCE TO SHAPE ITS FUTURE

On the other hand, were the producers in a position to go before a committee of Congress and point to the fact that they had selected a highly qualified man from among their number to act as the industry's premier, and that he had been given broad powers and was possessed of those requisites of personality and prestige to insure united action along constructive lines, the unquestioned reaction on the part of a majority of the legislators would be to give the industry a chance to work out the program which it had launched.

Such a leader might have been able to persuade the operators in Somerset County and the Connellsville district that it was not the constructive thing to cut wages to the extent they did, at just that time at least. He might have been able to obtain a pledge from the non-union operators that they would make only a proportionate cut were the union operators successful in getting a small reduction. It is entirely possible that a man of personality and of force could have saved that strike situation, thereby preventing its costly aftermath and a nationwide demand for regulation.

Even had the industry's premier failed in his efforts to prevent the strike, he could have taken a desk in Secretary Hoover's office and rendered great assistance in voluntary price control. When the operators in western Kentucky refused to agree, he could have jumped on the train and pointed out to them, face to face, that they were insisting on a course which would do much to fasten permanent

THE UNREMUNERATIVE CHARACTER of many coal operations is shown by the statistics just compiled by the Bureau of Internal Revenue covering income tax returns during 1921. Out of 3,656 corporations engaged in the mining of coal, 2,577 had no net income whatever and suffered deficits aggregating \$72,521,815. Of the total, 1,079 corporations had a net income of \$82,654,787 and paid a total tax of \$15,219,444. Of that amount, \$6,922,882 was income tax and \$8,296,562 was war profits or excess profits tax.

regulation on the coal industry. On the other hand, he could have convinced Mr. Hoover, no doubt, that the Kanawha operators should have been allowed to have a higher price, in view of their special difficulties in keeping their mines in operation.

Parker Protests That Trade Commission's Anthracite Reports Are Misleading

The Federal Trade Commission's reports on the anthracite industry are misleading the public, according to E. W. Parker, director of the Anthracite Bureau of Information, Philadelphia, who wrote the following letter of protest to Victor Murdock, chairman of the Commission, Oct. 31:

"On behalf of the anthracite industry as a whole I must earnestly protest against the manner in which the series of reports on anthracite now being issued by the Federal Trade Commission are prepared. Instead of indicating the exact quantities of anthracite, expressed either in cars or tons, which have passed through the hands of one or more wholesale dealers, the information is expressed in percentages, without any reference whatsoever to the relationships such percentages bear to the total production of anthracite.

"It is well known in the industry that the total quantity of anthracite which is sold through wholesalers or jobbers is relatively small. The manner in which the facts are given to the public through the Commission's report is entirely misleading. I am inclosing herewith an editorial taken from the *Evening Bulletin* of Philadelphia, which shows that according to its interpretation of the commission's report, no less than 93.8 per cent of the total production of anthracite passed through the hands of these wholesalers. Expressed in percentages the reports may be based on insignificantly small quantities. They certainly do not apply to the 70,000,000 tons of anthracite production.

"The same objection applies to the portion of your report under the subhead 'High Prices Charged by Mine Operators.' The statement shows that one-third of the tonnage was sold at more than \$12 a ton, but does not indicate what quantity these sales represented nor their relationship to the total anthracite output.

"It is not then, I trust, presuming too much to request of the Federal Trade Commission that in the future reports of this series the quantities of anthracite passing through the hands of wholesalers shall be definitely stated."

Navy Receives 11 Bids for Storage Coal

At the Bureau of Supplies and Accounts, Navy Department, bids were opened Nov. 1 for furnishing 25,000 tons of steaming coal for delivery into storage at the Naval Fuel Depot, Sewalls Point, Va. The proposals received were as follows, all being f.o.b. Sewalls Point, except where otherwise specified:

C. G. Blake & Co., Cincinnati, \$5.02 per ton; W. H. Brown Coal Co., Inc., Norfolk, \$4.42 per ton; Castner, Curran & Bullitt, Inc., New York, \$5.32 per ton; Eastern Coal & Export Corporation, Richmond, \$4.75 and \$5 per ton; Fayette Smokeless Fuel Co., Mt. Hope, W. Va., \$4.87 per ton; Lake & Export Coal Corporation, Huntington, W. Va., \$2.17 per ton, f.o.b. mine; Leckie Coal Co., Inc., Columbus, Ohio, \$5.75 per ton; Low Volatile Consolidated Coal Co., Beckley, W. Va., \$5.32 per ton; Raleigh Smokeless Fuel Co., Beckley, W. Va., \$5.34 per ton; Smokeless Fuel Co., Charleston, W. Va., \$5.52 per ton. An informal bid was received from the Steamship Fuel Corporation, New York.

HEARINGS BY THE FEDERAL TRADE COMMISSION into pyramiding of anthracite prices, which will begin in Washington, D. C., Nov. 19, will be conducted by the full commission. The hearing is expected to last about a week. Conduct of the inquiry by the whole commission is unusual, as heretofore cases heard by the Commission have as a rule been handled by one or two commissioners and an examiner.

Cessation in Hearings of Appeals On Anthracite Tax Valuations

301 Actions Involving Many Millions Enlist
Legal Lights—Commissioners' "Expert" Kites
Values—Numerous Assessments Reduced

After four weeks of taking testimony, the Schuylkill County courts have temporarily discontinued hearings in the appeals of anthracite land owners from the triennial assessment of 1922, the regular civil and criminal terms being due now. These tax cases, comprising 301 separate actions on the court calendar and involving originally the services of more than 30 lawyers from New York, Philadelphia, Scranton, Wilkes-Barre, Reading and Pottsville, are the most important in the history of the anthracite industry.

The issue is this: In 1921 Schuylkill coal lands were assessed for tax purposes at approximately \$63,000,000. In the 1922 triennial assessment the County Commissioners increased this to approximately \$422,000,000. This figure, they said, was only 60 per cent of the market value of the lands, so that the actual market value, according to the County Commissioners, was \$703,000,000. The minority Commissioner, Peter J. Cuff, took the stand and swore that he thought the true market value was \$1,000,000,000 and that he had endeavored to have that figure adopted.

Coal-land owners have maintained that these values were inflated and unjust. They proved, by thousands of instances taken from the public records, that other private properties sold in 1921 had been valued in 1922 at as little as 2.2 per cent of sale price and that the average 1922 valuation of all properties other than coal sold in 1921 was less than one-third. The County Commissioners agreed that they would make their valuation only 45 per cent of market value instead of 60 per cent. This meant that even if the supposed market value of \$703,000,000 were retained, the taxable valuation would be a little over \$316,000,000 instead of \$422,000,000. The cases thereupon went to court upon the issue of determining the actual market value of each tract in the county, to which value, when established by the courts, the ratio of 45 per cent would apply.

SIMPLE PROCEDURE OF AN "EXPERT"

The methods used by the County Commissioners, as testified to in Court, were: County Engineer S. G. Crawford was assisted by one W. C. Monroe, from Scranton, as an "expert." Mr. Monroe has made a business of posing as "expert engineer" for County Commissioners wishing to kite coal-land values, and he has been known to take jobs on a sliding scale basis—a percentage on the final increase in valuation. He had such a contract in Northumberland County last year, and the court there threw it out with considerable tart comment.

Monroe and Crawford took the Geological Survey maps and sections, and from these calculated coal areas and bed thicknesses. It was simple multiplication to get cubic contents on tonnage theoretically in place. In most instances they used 15c. a ton as the value of recoverable coal. Dividing the amount so obtained by the number of acres in the areas under discussion, they arrived at an average value per acre.

As matters now stand, the appeals which are being heard are those of the Philadelphia & Reading Coal & Iron Co. and affiliated interests, comprising 45 separate cases, and 18 of the Lehigh Coal & Navigation Co. and its affiliated concerns.

The procedure in each instance is much the same. The county formally proves assessment and then introduces its "experts," Monroe and Crawford, to sketch the procedure of valuation. The appellants then bring on their witnesses to prove actual market values. In the Reading appeals from the Blythe Township valuations, for example, the actual market value per acre was said by the county to be \$6,132. The Reading offered as witnesses Chief Engineer John F. Bevan, Assistant Engineer W. A. Richards, Division Superintendent Fred C. Caldwell, of Shamokin; W. S. Pugh, former city engineer of Pottsville; George Stevenson,

of Stevenson & Knight, Scranton; Arthur W. Sheaffer, consulting engineer, of Pottsville, and several of the Reading's own division engineers.

These men, after careful analysis of each tract in Blythe Township, placed valuations not to exceed \$1,500 on the best lands and almost nominal sums on lands in the Sharp Mountain basin or under surface set aside for watershed purposes. In every instance these men knew of sales, public and private, of comparable lands, which sales they took into consideration, as the Pennsylvania law directs.

Every man told of the impossibility of calculating the amount of coal in place in a virgin tract. Mr. Bevan showed that it was impossible to determine the amount in a developed tract. He said that any might pinch out unexpectedly, and frequently did, so that within a short space there might be 10 ft. of coal in a gangway and then a thickness of only a few inches. He analyzed the veins in the Blythe Township lands as shown by engineers' maps of the Eagle Hill and Silver Creek collieries. Every vein is there from the Little Diamond down to the Lykens Valley—eleven in all, counting the three splits of the Mammoth as separate.

He testified that the Buck Mountain and Lykens Valley beds there are unworkable. Of the remaining nine, two—the Diamond and the Skidmore—pinch out at places, while the Orchard at one place pinches down to 6 in. of coal.

SAYS ESTIMATES OF TONNAGE IN PLACE IS GUESSWORK

The total thicknesses of the nine workable beds, so far as developed, vary from 30 ft. 6 in. to 93 ft., but the actual coal content in these beds varies from a total of 17 ft. to 59 ft. Mr. Bevan said that in the Schuylkill field nobody could tell what was a hundred yards, or even a hundred feet, ahead, and that any estimate of tonnage was nothing but guesswork.

In the same way he testified that it was impossible to fix any percentage of coal in place as recoverable, since nobody could tell what the character of the top rock would be, whether the coal would be crushed, or whether the coal would be friable. The only certain thing, he said, was that the deeper the workings went the less coal was recovered, owing to the overhanging weight which crushed pillars and even unmined coal.

Monroe admitted that he had placed an average valuation of \$6,132 on every acre of land in Blythe Township held by the Reading, and also admitted that they lay in three basins—northern, middle and Sharp Mountain. He admitted that the middle basin was much more valuable than either of the others, but that he had placed a flat valuation on each. He said he had never seen the veins on the property and had never been in the mines there. He also said that he considered that 50 per cent of the original coal content was recoverable, but could give nothing but his "experience" as basis for that estimate.

He said the Reading lands in Blythe were worth, in the market, \$32,507,165. He then said that the total recoverable coal in the lands was 171,813,692 tons, worth 15c. a ton in place. He was told to multiply that out, and seemed nonplussed to find that the total was only \$25,112,053, or more than \$6,000,000 less than his total valuation. He knew nothing of any tract and could not tell what veins specified tracts contained, yet he valued them at \$6,132 per acre just the same.

That the County Commissioners themselves take little stock in their handiwork seems apparent from the peculiar developments since these cases began on Oct. 8. To begin with they lopped off more than \$100,000,000 by the agreement on a 45-per cent ratio. Then the compromisers began to get busy, assisted by one of the judges. The Hudson Coal Co., which was assessed at \$1,739,000 in 1921 and at \$15,970,836 in 1922, settled on a new assessment of approximately \$3,750,000.

The Girard Estate then fell into line. Assessed at \$4,712,279 in 1921 and at \$24,297,110 in 1922, it agreed to a new assessment of approximately \$12,000,000. The Lehigh Valley Coal Co., assessed at approximately \$5,000,000 in 1921 and approximately \$31,000,000 in 1922, settled on a new assessment of about \$12,500,000. Others tumbled into line on settlements involving anywhere from 100 to 150 or 160 per cent over the 1921 valuation.

Production and the Market

Weekly Review

Production of bituminous coal is not suffering any decrease as the season advances. The curve of production is a straight line. During the week ended Oct. 27 10,908,000 tons of soft coal was produced, an increase of 214,000 over the previous week. Preliminary estimates for the week ending Nov. 3 indicate no change in the rate of output. The total production at the end of October is practically equal to that of 1917 and 1920 for the same period, but about 30,000,000 tons below the record year, 1918.

Coal Age Index of spot prices of bituminous coal declined one point last week to 183 on Nov. 5, which corresponds with an average price at the mines of \$2.21.

The tidewater market is flooded with coal.

GOVERNMENT BIDS AS TRADE INDICATORS

Bids opened Nov. 1 for 25,000 tons of Navy standard coal, f.o.b. Sewalls Point, resulted in tenders ranging from \$1.90 to \$3 per gross ton f.o.b. mines.

Bids submitted Oct. 31 to the Government Fuel Yards on 14,700 gross tons of smokeless coal for B. & O. delivery, District of Columbia, from Nov. 15, 1923, to March 31, 1924, ranged from \$2.03 gross ton at the mine by the Valley Camp Coal Co., Salco Mine, upward to \$3.64 as the highest bid by J. B. Haught. The majority of the bids were between \$2.20 and \$2.60.

Some inquiries for export coal are being received but there is little actual business placed.

Colder weather slightly improved the domestic-coal market in the Middle West but with no effect on the steam-coal market. There is the usual speculation as to what will happen when the million tons a week now going to the Lakes is thrown on the local markets when navigation closes. The Ohio markets are inactive, prices low and irregular. The Pittsburgh district is saturated with unsold coal and there is no market in New England for spot coal. Dumpings at Hampton Roads during the week ended Nov. 1 amounted to

344,120 net tons, as compared with 259,158 net tons the previous week.

Lake shipments continue close to 1,000,000 net tons weekly, although the season is drawing to a close. Cargo coal shipped during the week ended Oct. 29 amounted to 918,764 net tons.

Although the miners observed Mitchell Day, Oct. 29, by remaining away from the mines and there have

	Week Ended Oct. 29	Season to Oct. 29
Cargo	918,764	25,490,681
Fuel	48,785	1,389,754
Totals	967,549	26,880,435

been idle days for other operations because of local labor troubles, production of hard coal last week is believed to have been between 1,700,000 and 1,800,000 net tons, or between 269,000 and 369,000 net tons below the output for the week ended Oct. 27, which was 24,000 tons ahead of the output for the previous week. Demand for the larger sizes continue active, but pea coal is easier. Difficulty is found to keep down the accumulations of the steam coals and most dealers find it necessary to make concessions in order to move their tonnages. During the week ended Oct. 29 69,771 net tons of hard coal was shipped up the lakes from Buffalo.

and Erie, according to the Geological Survey, bringing total shipments for the season to 2,830,590 net tons.

Midwest Coal Moves Better

Slow general improvement of conditions throughout the trade are noted in Chicago and the other Midwest markets. Cooler weather for several days up to the end of last week raised the immediate demand for domestic stuff of various sorts, but of course was not effective enough to start anything resembling a market flurry. No important price advances were possible. Instead, circulars grew a little more firm at the levels operators have been trying in vain to maintain lately. Southern Illinois, for instance, instead of trying to push up the \$4.35 lump quotation, settled down to the business of solidifying the bottom at \$4.

The steam market has not changed noticeably. Buying is sufficient to absorb the running production and no more. Buyers still are of the opinion that they can do better a month from now, when domestic demand is stronger. Franklin County association producers manage to get \$1.40 @ \$1.50 for practically all their screenings with only occasional drops, though there are lots of cheap screenings to

be picked up all around them. Central Illinois sells mainly from \$1 to \$1.25 with the more anxious operators cutting down to 75c. now and then. Not much Standard district fine coal gets into the Chicago region nowadays, but some has been traded there at 50c.@60c.

Trade continues steady in hard coal, now retailing in Chicago for \$17 in the domestic sizes, but there is plenty available for all needs. Pocahontas trade has been light enough to nudge the mine price down from \$3 to \$2.50 on mine-run without any material effect on demand. Demand is fair and that is all.

St. Louis Trade Remains Dormant

Not enough of last week's cold snap got into St. Louis to have any material effect on the coal market. The whole region around that trading center remained in a carefree state of mind regarding fuel. A little movement of the cheaper grades was noted among retailers but the tonnage was too light to be important. Country domestic trade was idle too. Anthracite, smokeless and coke all are in light demand. In the steam trade wagonload is a little active but carload is slow. A movement of egg and nut

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

Index	1923		1922	
	Nov. 5	Oct. 29	Oct. 22	Nov. 6
Index	183	184	186	344
Weighted average price	\$2.21	\$2.23	\$2.25	\$4.16

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

to Omaha and Chicago removed some of the coal normally traded in St. Louis. Prices are practically unchanged.

In the southern Illinois field working time continues bad with a good many no bills of various sizes on track. This applies even to independents, who cut prices to get business. Railroad tonnage has fallen off. There is no stint of cars in that region. In the DuQuoin and Jackson County field conditions are similar to those in the territory just mentioned. There the mines with lowest prices appear to be getting the business.

In the Mt. Olive district there has been a little activity, but car supply as well as failure to move egg, nut and screenings is interfering with working time. The demand for domestic is just fair.

In the Standard district the only call for any size seems to be for 6-in. lump. All other sizes are hard to move, and some mines have been idle for many days on account of no bills. Car supply is good. All steam sizes are having a hard time.

Kentucky Feels Better

As a result of decision of the Interstate Commerce Commission granting the western Kentucky operators a rate to Minnesota and the Northwest at 25c. a ton over southern Illinois mines, there is better feeling in the western section of Kentucky this week, in spite of the fact that prices

are still draggy and steam business unsatisfactory. Screenings have bucked up a little. Car supply is reported off in a few sections, although the condition probably will not last more than a day or two.

With the first below freezing temperature coming on the night of Oct. 30, it looks as if the fall season is beginning to run to form, and Louisville trade is feeling much better concerning the general outlook. Retailers are meeting with a much better demand and jobbers report orders more numerous for prepared. Industrial business continues a bit slow, as many industries are well stocked.

However, some industrial buyers realize that when lake movement ceases screenings will be in small production, and a price advance of around 50c. a ton is predicted, or perhaps more. Screenings will stay enough under mine-run to force movement. As the lake shipping season is about over an increased demand for screenings at better prices is beginning already to be felt. Other than advanced prices for screenings in all state fields, and a little firmer holding of mine-run, prices show no material change.

Northwest Market Improves Slightly

A wave of real snappy weather put a little life into the Northwestern coal market during the past week. The effect was largely upon anthracite demand, however, and that was none too marked, for a good deal of hard domestic fuel has already been dumped into cellars. The slacking off of anthracite shipments to the docks is attracting some attention. Of twenty-three cargoes on their way to the Head-of-the-Lakes, only two are of anthracite. Milwaukee stocks of anthracite are not increasing as was expected either, and only a few more cargoes are booked for that port.

Soft coal fills the whole region, however, and is moving in without stint. Milwaukee has received 2,571,753 tons already this season and last week saw six boats at the docks, the largest line-up of the season. Receipts at Duluth-Superior are heavy, too. Prices continue soft and it is the opinion of wise observers that the top heavy market will sag eventually, in spite of the inevitable arrival of winter. Out through the selling field of the Northwest price cutting continues common, for competition is keener than usual at this time of year.

West Feels Cold Snap, Too

A week of cold weather in the Southwestern district brought little relief to the screenings market. The market for lump and nut remains steady, with a few companies advancing the price of these two grades in Kansas coal 25c. to 50c. the first of the month. The increase was not general. Mines are operating from 60 to 70 per cent time.

Utah producers are very long on slack. Dealers have had a good month but business is slowing up a bit. Car shortage continues though it is not bothering the local dealers. Real winter weather for several days would probably embarrass them, however, as the supplies in the local yards are below normal. Prices have not changed.

In Colorado the coal situation has changed slightly during the past week, inasmuch as the mines are working on an average of three to three and a half days a week now, although the majority of the operators still report few orders.

Ohio Markets Are Featureless

There is no outstanding feature in the Ohio trade. At Columbus prices are low and irregular and there is no special strength to the demand. Everybody seems to be playing a waiting game. Producers and distributors are selling only a fair amount of coal and hoping for a better demand when cold weather arrives. Steam-coal business is dull and buying practically only when distress coal can be had cheaply. With the railroads not taking as much tonnage as formerly, the utilities are the best customers. Screenings are extremely dull.

The Cincinnati market is dull. Buying is slow and prices easy. While smokeless lump and egg are quoted around \$6 on the November circular the spot market runs as much as 50c. lower and even under that figure to brokers. Mine run is quoted at \$2.50 but sales of the best Pocahontas No. 3

have been made as low as \$2 and there has been quite a movement of prime New River coal of the best preparation as low as \$1.75. The closing of the lake season is expected to throw considerably more coal into the inland market which it will be asked to absorb.

Reports received at Cleveland indicate that as a result of work in other sections of Ohio there has been a steady influx of miners into eastern Ohio, where continued operations of the mines is attributable in the main to production for railroads and shipments to the Lakes. Retail stocks are moving slowly, while steam demand continues negligible and inquiries are few.

Production in the Pittsburgh district continued downward. Now and then another mine closes, but others vary their output according to circumstances. Prices are not trending downward definitely but can hardly be said to show any stiffening tendency. General quotations do not indicate much because buyers are so discriminating, having things their own way, that there is quite a range according to quality in the open quotable market. Demand for domestic coal is regarded as somewhat poor for this time of the year. Byproduct coal is in poor demand.

Conditions in central Pennsylvania are very unsatisfactory to the operator and miner. There is evidence that some large operators will close down some of their mines and operate others on full time, intending in this way to reduce the cost of production. Many of the mines now working are on short time. Loadings during October were approximately 62,000 cars, a decrease of 6,000 from September loadings. The number of no-bill cars on side track at the end of the month was estimated at 1,800.

There is no activity in the Buffalo market. Buying is practically at a standstill, and some shippers believe it is getting worse. Considerable coal is being offered dealers and low prices prevail.

Bright Spots Lacking in New England

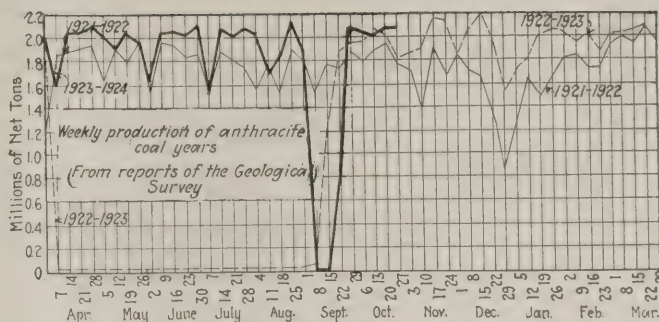

In New England the market drags along without any bright spots whatever. There are accumulations not only at the Virginia terminals but at discharging plants at this end, and in every direction quotations are soft. There is practically no buying except under pressure of special offers and at this writing it is difficulty to see how there can be any improvement during November.

No. 1 Navy standard Pocahontas and New River are to be had at \$4.30@4.50 per gross ton f.o.b. vessel, and on cars Boston and Providence the quotations of last week have been shaded. As low as \$5.35 per gross ton has been rumored f.o.b. Boston, while a few factors are trying hard to raise the price level to \$5.75. Reserves are heavy among all the industries in this territory and there is not enough coal being consumed to warrant any prediction of firmer prices in the near future.

The market for steam coals from central Pennsylvania continues extremely dull. Neither f.o.b. mines nor at the Philadelphia and New York piers is there anything more than scattering demand and prices are correspondingly depressed.

Receipts High, Prices Low, at New York

Heavy receipts at tidewater and low prices rule the New York market. On Nov. 2 there were 2,445 cars of soft coal reported on tracks at four of the largest piers while

the dumpings for that day amounted to but 346 cars, the average dumpings for the first five days of last week were 450 cars. There is little of the cheap coals to be had, most of the demand being for the better grades at low prices. Contract coals continue to move in fair volume, but many original prices have been shaded in order to keep it in transit.

Producers in the Philadelphia market are complaining, and are not able to operate their mines at anything like full time. The cutting of contract prices by some companies has been followed by other concerns, the spot market responding to the reduction.

Conditions at Baltimore are flat. Large consumers continue to buy in the open market and at times are able to pick up bargain lots. The situation appears to be growing worse so far as the prices of West Virginia coals are concerned.

A fairly good domestic market has been maintained in the Birmingham district because of weather conditions, little effort being required to move all of this grade of coal produced. The steam market shows no marked change and inquiry is slow. Production during the week ended Oct. 20 was the lowest for the present year, amounting to 333,000 tons. Labor is plentiful in the coal fields, a decided increase being shown in the number of applications for work.

Anthracite Market Gradually Easing

The hard-coal market is slowly becoming easier. While some retail dealers lack sufficient receipts to take care of their trade most consumers have some coal in their bins or are able to get it within a short while. Some shippers in order to keep down their supply of soft coal or the anthracite steam sizes induce their customers to take a portion of either of these coals with their order for the domestic coals and in many instances the buyer, having no immediate need for the soft coal or the steam sizes returns them to the market for sale. In some instances where a combination order is arranged concessions are made on the quotations for the domestic coals. The market was slightly affected by the lower temperatures that prevailed last week but there was no considerable urgency. Pea coal, next to the buckwheats, is the longest of the anthracite sizes, and shippers are having no difficulty to keep it on the move. The steam-coal situation is becoming serious. The larger operators are storing these coals, particularly buckwheat No. 1, while they are accumulating with the more prominent independent producers. The smaller independents are disposing of their coals at prices much under the company schedule.

Beehive coke production during the week ended Oct. 27 amounted to 276,000 net tons, says the Geological Survey, a decrease of 10,000 tons when compared with the previous week, establishing a new low record for this year.

Foreign Market And Export News

Slight Increase in British Coal Production; Newcastle Market Improving

An increase of 55,000 tons was made in the coal output of Great Britain's mines during the week ended Oct. 20, when compared with the previous week, the production amounting to 5,680,000 tons, says a cable to *Coal Age*.

The Welsh coal trade is still unsettled though somewhat steadier, owing to a recovery in the demand from Europe. Output of coal is high and mine suspensions, though not so frequent, are serious. The accumulation of stocks is enormous and operators are offering concessions to buyers who will take immediate delivery. Operators decline to see forward on current prices as many mines are not covering their operating expenses.

There is practically no contracting for next year, the large consumers abroad only inquiring with a view to testing the position and holding back the business in the hope of securing further reductions in price by waiting.

The Newcastle market is improving rapidly, both for forward and prompt positions. German inquiries are slow, though those from Italy and Scandinavia are strong. Most of the mines have sold their outputs to the middle of November.

Hampton Roads Market Weak

Conditions at Hampton Roads continued unusually dull last week, with the market weakening and inquiries negligible. The bunker trade alone appeared to be holding its own, although New England trade showed prospects of increasing.

Over production was given by shippers as the cause of the slump which has featured the local market for several weeks. They did not anticipate prices reaching a lower level, because they had already gone well below the low point for several years.

Domestic trade was pronounced dull, also, stocks having been laid in heavily several months ago in anticipation of strike difficulties. The tone of the market was exceedingly weak.

French Miners Want More Pay

Demand for industrial coals are being easily met by the French mines, but users of domestic coals are facing a shortage as soon as the demand increases. While prices are being maintained, a change is expected as a result of the demands of the miners for an increase in pay.

Imports of British coal slightly improved during the last week in October, but were still below the receipts for September. Concessions were made for prompt deliveries and terms for forward contracts remained firm.

Consumers are showing more interest in coals from the United States and inquiries are increasing.

Panama Canal Coal Shipments

Shipments of coal and coke through the Panama Canal from the Atlantic to the Pacific Ocean during the fiscal year ended June 30, 1923, amounted to 280,343 gross tons, as compared with 404,389 tons in 1922, says the *Panama Canal Record*. Of this tonnage there were 182,829 tons of coal and 97,514 tons of coke, of which 99,254 tons of coal and 80,364 tons of coke came from the British Isles, and 82,480 tons of coal and 14,762 tons of coke originated in the United States. The west coast of South America received 91,755 tons of coal, the United States 66,174 tons, and 7,676 tons went to Hawaii. Of the coke shipments 54,998 tons was destined for South America, 40,856 tons to the United States and 1,228 tons to Australia.

News Items From Field and Trade

COLORADO

The U. S. Land Office at Glenwood Springs has been directed by the Secretary of the Interior to offer for lease a tract of public coal land in Colorado containing approximately 560 acres. The land is in Garfield County in the Grand Hogback coal field. Lease for this tract will be at a government royalty of 10c. per ton for coal mined, a minimum investment in mining operations of \$125,000 during the first three years of the lease, and a minimum production of 120,000 tons of coal a year beginning with the fourth year of the lease.

ILLINOIS

The B-B Coal Co. mine, on the Southern Ry., near Belleville, has suspended operations. More than 100 men have been employed. The B-B is the twentieth mine in the Belleville subdistrict to shut down since April 1.

Two Peabody Coal Co. men of the company's headquarters in Chicago were killed Oct. 27 when the wire of a radio aerial they were erecting made contact with a high-potential line of the Commonwealth Edison Co. They were Albert F. Goepfinger, auditor for the company, and William J. Quinn, an accountant. A third man who tried to drag the writhing pair away from the "hot" wire also died.

J. C. Howell, of the Howell Coal Co., Champaign, has opened an office in the Fisher Building, Chicago. R. L. Dincombe will be in charge of the new office. Mr. Howell will continue to reside in Champaign and will maintain his office there.

Jewel No. 1 of the Jewel Coal & Mining Co. has closed down at Du Quoin. Jewel Nos. 1 and 2 are both comparatively new mines and are under the control of the Sterling-Midland Company, Chicago.

The Rex Coal Co., Davenport, Ia., which operates a mine at Warner, Ill., at its annual meeting of stockholders in the Chamber of Commerce rooms in Davenport elected these directors: Hugh V. Pirt, C. A. Curry, W. A. Carlson, H. E. Bishop, Frank McGugin, C. W. Krueger, A. G. Vogel, James Van Arsdale and G. G. Gatrell.

The Illinois Mining Institute holds its annual meeting in St. Louis, Mo., November 24 at the American hotel, at 10 A.M.

The American Coal Sales Co., 360 North Michigan Ave., Chicago, has been incorporated with capital of \$25,000, as a jobber in coal. The incorporators are Robert W. Kruse, H. E. Larkin and E. L. Verplanck.

After failing to meet two payrolls within three months' time the Jackson Coal Co. resumed operations again the week of Oct. 22 at Hallidayboro. The company, which has main offices in Connellsville, Pa., went into the hands of a receiver Oct. 15, following the second failure to meet the bi-monthly mine payroll and the mine shut-down.

Eureka mine No. 1 at Marissa, which had been closed down since early last April, has resumed operations again. Borders No. 1, in the same district, recently closed indefinitely.

Perry O'Neal, for some time past chief electrician at Mine No. 16 of the Old Ben Coal Corporation at Sesser, has been transferred to Mine No. 14, at Buckner.

The Black Servant Coal Co. recently shipped its first carload of coal from its new strip mine at Elkville. The mine, just completed, is the last word in strip mining and uses the latest machinery on the market, including large electric stripping shovels. The output of the mine is screened and rescreened into various sizes putting the coal on a grade with any other in the district.

The Victory Coal & Mining Co.'s mine at DuQuoin, controlled by the Boehmer Coal Co. of St. Louis, has closed. The Boehmer Coal Co. besides operating several mines in the Belleville district, enjoys a good retail trade in St. Louis. Three years ago the company took over an old property at

DuQuoin, which it remodeled and up to this time has operated steadily.

There has been a shortage of water at several mines in the Southern Illinois field and some mines on the Mobile & Ohio R.R. have had to have water hauled by the railroad to keep their plants going. Recent rains helped the situation some.

The Shed Coal Co. is opening a stripping property near New Denison and soon may be dumping coal into cars on the Illinois Central from a narrow-gage line built from the mine to New Denison. It is expected that the new narrow-gage line will some day serve a number of properties along the right of way.

INDIANA

The Orton & Steinbrenner Co., Chicago, Ill., manufacturers of locomotive cranes, buckets and coal crushers, have just completed a large addition to their works at Huntington, Ind., which will approximately double the output of the Company. All equipment, including a large number of the most modern machine tools, has been purchased and most of it is already in use.

Two carloads of Indiana screenings from the Templeton Coal Co., of Terre Haute, have created considerable interest by starting for Denver, Colo. This is the first shipment known to have gone from Indiana so far west. It is a special coal for foundry use by the Griffin Wheel Co. Although the price of such coal in Indiana is low, the cost delivered in Denver is about \$15, most of which, of course, is freight.

KENTUCKY

The Fordson Coal Co. of Stone has contracted with Roberts & Schaefer of Chicago for screens and loading booms to be installed at these mines: Pansion Junction, Nos. 2 and 1-11 at Hardy, and Nos. 6 and 7 at McVeigh.

The Bertha-Consumers Co., of Pittsburgh, Pa., announces that the post office address of Elsie Mines No. 1, 2 and 3, formerly known as Dalna, has been changed to Elsie coal. The post office address of Elsie No. 4 at Blackey, remains unchanged. Through the courtesy of the Louisville & Nashville R.R., the railroad billing stations have been changed as follows: Dalna, changed to Elsie coal; Smoot, changed to Elsie No. 1; Wevaton, changed to Elsie No. 2, and Woodrock, changed to Elsie No. 4.

The Kentucky Jewell Coal Co., of Lexington, capital \$25,000, has been incorporated by H. E. Bullock, M. O. Bullock, and J. W. Owens, all of Lexington.

Whitesburg reports that the recently formed Sutton Coal Co., in Pike County, will sink a mine and build a new town soon and that it plans to start shipments early next year.

It is reported that the Whitesburg Coal Co. operations at Whiteo have closed down indefinitely on account of low prices and lack of business.

W. F. Bradshaw, coal operator, banker and insurance man of Paducah, was on Oct. 19 appointed a member of the Child Welfare Commission by Governor E. P. Morrow.

A rescreening plant is now being built by Roberts & Schaefer for the W. G. Duncan Coal Co. at its mine in Greenville.

MINNESOTA

George H. Cushing is to talk before an open forum of the St. Paul Association on the coal situation of the Northwest on Nov. 14.

Much interest was shown in the report of the Federal Coal Commission relating to the situation in the Northwest, especially as it indicated that the retail trade has not been getting undue profits. County attorney Olson, of Minneapolis, who has been conducting an investigation into the coal costs, says that the independent coal companies are prospering, despite the handicaps indicated, as they are buying all-rail coal, and their number is increasing.

NEW JERSEY

The Irvington-Hilton Coal Co., of which the late Mayor Edward R. Folsom was president, has been sold by auction to Louis Folsom & Co., recently organized by Louis Folsom, son of the Mayor and vice-president of the bankrupt concern. A telegraphed bid of \$4,000 was received from George H. Woolley of St. Petersburg, Fla., formerly of Irvington. Louis Folsom's bid was \$4,200. The aggregate of bids for separate parcels of the equipment amounted to about \$2,200.

NEW YORK

During the first eight months of 1923 there were 473,657 cars of soft coal loaded at mines located on the New York Central lines, which was an increase of 23½ per cent over the number loaded in the corresponding period of 1919; 1.5 per cent over 1920; 46.7 per cent over 1921, and 153.5 per cent over 1922. Up to the end of August the New York Central lines dumped at Ashtabula and Toledo for lake shipment 64,233 cars of bituminous coal, which was 17.2 per cent of the total dumped by all other railroads at all Lake Erie ports.

H. H. Merrett, managing director of D. R. Llewellyn, Merrett & Price, Ltd., producers and exporters of coal, Cardiff, Wales, who has been in the United States for the past few weeks, sailed on the Aquitania, Oct. 22.

The Virginia Iron, Coal & Coke Co., for the quarter ended Sept. 30, 1923, reports gross income of \$279,842 against \$402,714 in the corresponding period last year. After allowing for interest, taxes and other charges there was reported net income of \$170,414, which, after allowing for preferred dividends, was equal to \$1.07 a share on the \$10,000,000 capital common stock outstanding. In the same quarter last year the net available for the common stock, after preferred dividends, was equal to \$2.11 a share. For the first nine months of the current year the company reports gross income of \$844,425, against \$679,117 in the same period last year. Net income after interest, taxes and other charges was \$528,957. This amount after preferred dividends was equal to \$3.41 a share earned on the common stock, against \$1.01 a share earned on the common stock in the first nine months of 1922.

The Empire Coal Mining Co., of Philadelphia, has opened a branch office in the Marine Trust Building, Buffalo, with K. P. Lewis, formerly sales manager of the Somerset & Cambria Smokeless Coal Mining Co., as resident manager.

Seymour Whitley, several years Buffalo agent of the Pittsburgh Coal Co., announces that he is going into the business on his own account. The Pittsburgh Coal Co. has appointed A. S. Fisher, of the Pittsburgh office, sales manager and P. B. Ballou, from the company's office in Erie, Pa., sales agent to succeed Mr. Whitley.

John Hays Hammond, chairman of the U. S. Coal Commission, was made head of a department of current economic and political movements, organized as a new branch of the National Civic Federation, at a luncheon given in his honor Nov. 1 at the Lawyers Club, New York City, by Judge Alton B. Parker, president of the federation. The department Mr. Hammond is to head will have for its aim the gathering and dissemination to the general public of information on domestic and world affairs. He will be aided in his work by a committee consisting of Louis Wiley, Henry S. Pritchett and Colonel R. M. Thompson. National experts in all fields will be asked to assist in the development of this group program, it was announced.

To his series of lectures on "A One Hundred Per Cent American Program" and "Fundamentals of Social Work," Edward T. Devine, member of the U. S. Coal Commission, has added a new topic "The Coal Industry of America—A Program for Its Stabilization."

The Buffalo Water Works received 21 bids, opened on Nov. 1, on its advertisement asking for 200 cars of slack coal, delivered during several weeks. The lowest was \$1. f.o.b. mine by the American-Canadian Co., Buffalo, and the Miller-Corson Co., Philadelphia. The highest was \$1.65.

OHIO

The new Philo plant of the Ohio Power Co., now being constructed in Muskingum County, will have coal-storage capacity of 400,000 tons. This is the largest amount that can be stored at any electrical plant in the

Ohio valley. A state canal paralleling the Muskingum River is being dredged for a distance of a mile and a quarter and when the work is complete the trough 30 ft. deep will be concreted. The canal will be filled with water and the coal poured into it from the railroad cars. The plant will use 3,800 tons of coal daily.

The Reeves Manufacturing Co., of Dover, is completing an aerial-tramway system that will transport its coal from two mines to galvanized sheet plant, a distance of five miles. An overhead cable slung from towers will carry steel buckets, each containing a ton of coal, and dump them near the furnace.

The Triumph Electric Co. and The Triumph Ice Machine Co., both of Cincinnati, announce that E. C. Morse has joined their organization as vice-president in charge of sales and as a member of the Board of Directors.

OKLAHOMA

A woman has actively entered the operating field in the Southwestern district, and has introduced the first steam-shovel outfit into her home county of Craig, in Oklahoma. She is Miss Pearl Holderman, who owns 1,000 acres of land just across the Kansas line. Miss Holderman's grandmother was a Cherokee Indian. When, back in 1916, Miss Holderman, a graduate of Kansas State Agricultural College, tired of teaching, for which she had prepared, she turned to the 40 acres of land she had received as a head right by reason of her Indian blood. In the seven years since, by her own efforts, she has increased her holdings to the 1,000 acres on which she has put her shovel to work.

PENNSYLVANIA

A new method of giving coal miners instruction to fit them for examinations for jobs as firebosses, mine foremen, assistant mine foremen and mine inspectors has been started in the anthracite districts of the state and Pennsylvania State College is ready to start in the bituminous districts. For several years, Penn State has had Prof. W. G. Duncan located in the bituminous fields supervising night classes for miners. Through a recent co-operative agreement with the college mining school, the State Department of Public Instruction and the State Bureau of Mines, this work has been greatly expanded. The college trains teachers for night classes and supplies the lesson material; the State Department of Mines conducts the examinations and the State Department of Public Instruction, when twenty or more miners of a community ask for the establishment of a class, assists the local school board in the maintenance of the work. Sixty-six lessons constitute the first year's work in anthracite mining; twenty lessons in mining electricity and twenty in mining mechanics. The bituminous-coal mining course consists of sixty short lessons.

F. E. Pratt, paymaster of the Dexcar Coal Co., operating mines at Ashville, Cambria County, was held up and robbed of the company payroll, amounting to \$6,200, on Oct. 26, on a lonely road near the scene of mines where he was going to pay the miners. R. J. Haverty, a private detective, on Oct. 31, arrested Dennis (alias Pawnee Bill) Delozier and Clarence Delaney, at Coupon, Cambria County, and both were held for trial in the Cambria County courts. The Dexcar company offered a reward of \$500 for the arrest and conviction of the bandits.

Auditor General Samuel B. Lewis on Oct. 24 called off the hearing he had set for that day when Rush N. Hosler, superintendent of the coal-mine section of the Pennsylvania Compensation Rating and Inspection Bureau, was to have been brought before him upon subpoena. Mr. Hosler had refused to permit certified accountants employed by the Auditor General to audit the books of the coal-mine section, although the accountants had found that the Insurance Fund had turned over to the section \$250,000 of state money. Superintendent Hosler was directed by the executive committee of the coal mine section to appear and furnish all necessary papers and books in so far as they relate to the State Workmen's Insurance Fund. Accompanied by counsel, Hosler appeared before the Auditor General prior to the time fixed for the hearing and expressed a willingness to co-operate with the accountants. The audit of the Insurance Fund books was made as the result of the passage of a law of 1923 which gave the Auditor General the right to audit the books. The fund in the past had maintained it was not subject to audit by the state.

State Secretary of Mines Walsh completed a series of conferences in Allentown last week with the inspectors of the anthracite region, the purpose of the meeting being to discuss mining methods and practices with a view to providing, if possible, greater safeguards for the work men, the head of the Mines department said. The record of each of the anthracite inspectors, covering a period of several years, has been analyzed in an effort to see why accidents should be greater in number in some districts than in others, the Department of Mines announced. A similar analysis has been made of the casualty record of the various operators and it is the hope of Secretary Walsh, he said, that the number of accidents can be lowered as the result of having presented these facts to the inspectors.

The Carnegie Steel Co. plans to enlarge its coal unloading equipment at the Clairton plant. The plant now has two cranes which unload 13,000 tons of coal per day, each crane having a capacity of six tons per lift. It is planned to install two cranes of similar capacity soon.

The Blacker Engineering Co., Inc., Grand Central Terminal, New York City, manufacturer of Blacker Blacksmithing Hammers, have opened an office in Pittsburgh at 421 Wood Street with George Hesse as district manager.

Edward Manning, colliery superintendent of the Greenwood colliery, of the Hudson Coal Co., Minooka, at a meeting attended by about 350 employees of the mines held recently offered a cash prize of \$250 to the employee who submits before Dec. 1 the best analysis and paper on mining practice at the face. The meeting was a second of a series of educational meetings and was addressed by B. T. Jones, senior assistant inside foreman, Mine Foreman John D. Price and Mr. Manning. The speaking was allowed by an entertainment.

W. L. Buchanan, general manager of the Hudson Coal Co. was the principal speaker at the initial meeting of the Powderly-Coalbrook Safety Institute, at Carbondale, on Oct. 24. Other speakers were W. L. Weickel, colliery superintendent at Powderly; William Davidson, colliery superintendent at Coalbrook; Fred Gilbert, chief clerk at Powderly, and Karl Hughes, colliery engineer. Following the addresses a general discussion among the men was carried on, when several good suggestions on the problem of safety were made. It was decided to offer a number of cash prizes for the writer of the best compositions on the subject, "Work at the Face," the decisions to be given out at a later meeting.

All of the property and assets of the Archbald Coal Co. have been acquired by the Suffolk anthracite collieries. The acquisition will increase the Suffolk's reserves by approximately 3,000,000 tons and increase daily output about 100 per cent.

The Adah mine of the H. C. Frick Coke Co. at Adah, in the sixth pool, Monongahela River, recently established a record in loading 13 standard steel barges with 10,800 tons of coal.

Robert Y. Stuart, Secretary of the Department of Forests and Waters, has sent to each mining company in Pennsylvania a letter offering the department's co-operation in the planting of trees. In this he said that the mining companies in the State during 1923 have planted 1,139,000 trees and that since 1916 they have planted 3,185,000 trees.

The main office of the Keister-MacQuown Fuel Co., of Pittsburgh, will be moved Nov. 1 from the ninth floor to the thirteenth floor, west tower, of the Union Trust Building.

The Candlemas Coal Co., composed of Wilkes-Barre capitalists, is making rapid progress in the development of the old Silver Brook anthracite workings, idle for the last twenty-five years, following expiration of the lease of the Wentz Coal Co.

The Lehigh Coal & Navigation Co. announces that new stripping operations at the "burning mines," at Summit Hill, are to be opened next spring. A location for an incline plane has been established in the effort to extinguish the fire which has consumed millions of tons of high-grade coal. The company plans to open the stripping operation in front of the fire and remove the coal, so that the fire eventually will have to burn itself out when the coal in that particular locality is consumed.

Fire broke out in the Oakdale mine of the Carnegie Coal Co., near Pittsburgh, on Oct. 26, resulting from the ignition by open lights of oil which flowed from a pipe line following a cave-in of shallow cover. A 4-in. pipe line of the Pure Oil Co. passes over that part of the property of the coal company which is pierced by No. 1 butt entry.

The section affected by the fire consists of about 15 acres, which is a tentacle of the main body of coal and is overlaid by a shallow cover. Where the surface break occurred the thickness of the cover is about 15 ft.; rooms were driven but no pillars were taken out. Fortunately, at the time of the cave-in, the oil company was not pumping oil. It is estimated that about 300 gallons of oil standing in the pipe line drained into the mine. Ordinarily the flow is 300 bbl. per hour. Smoke from the fire overcame several miners, but all of them were rescued. Temporary brattices were erected by apparatus men as close as possible to the seat of the fire in order to clear the atmosphere of smoke on the outbye side of the temporary stoppings. Preparations were then made to erect concrete dams. The fire zone will be completely flooded in ten days' time by discharging water into the surface break from a pump with a capacity of 1,000 gallons per minute. It is expected that the fire will be quenched by this method. The main body of the mine is not endangered by the fire.

Governor Pinchot has sent telegrams to the Anthracite Operators Policy Committee suggesting that they come to Harrisburg to confer with him further relative to anthracite prices.

Planning to make a survey of business conditions in the countries of the Far East, Dean K. Chadbourne, manager of the department of the Far East of the Westinghouse Electric International Co., will sail from San Francisco the latter part of the month to visit Japan, China, the Philippine Islands, Java, Australia and New Zealand. Mr. Chadbourne's visit will result in closer relationships between the company and its representatives and agents in the Far East. He will also assist other Westinghouse officials in co-operating with Japanese officials and business men in the reconstruction of the area devastated by the recent earthquake and fire.

TEXAS

The Madison Oil & Coal Co., of which Hall Etter, Houston, is president and manager, will erect a tippie and power plant near Calvert, and will move machinery and some equipment from another location, but will want mine cars, mine rails, mine props and ties.

The Producers' Mining Co. has been organized at Bastrop, with capital stock of \$10,000. Incorporators are: E. S. Orgain, John Belto and Martin Belto. The company will mine lignite from the extensive beds near Bastrop.

UTAH

The Mutual Coal Co. of Salt Lake City has received permission to sell 2,500 shares of its stock at \$12.50 per share. The company has 49,703 shares outstanding.

The Blazon Coal Co. has filed amendment to its articles increasing its board of directors from three to five members.

The F. C. Richmond Machinery Co., representatives for The Conveyors Corporation of America, Chicago, have moved their offices and sales-rooms to 320 West Second South Street, Salt Lake City.

The Pahvant Coal Co. is offering to the public an issue of 500,000 first mortgage, 7 per cent serial gold bonds, due July 1, 1928 to 1938, and priced at 98 and accrued interest to yield about 7½ per cent. The company owns and has under option 840 acres of coal land in Spring Canon, Carbon County, a portion of which for immediate development is estimated to contain 6,000,000 tons.

WASHINGTON

The coal operators of the state are conducting a publicity campaign in defence of the Washington coal industry's right to live. It is repeatedly pointed out that the industry now employs about 30,000 people, directly and indirectly that it is the third largest industry of the state and contributes heavily to the state's welfare and prosperity. However, it is harassed by oil shipped in from southern California at a freight rate less than the average rate on Washington coal to Seattle, and by coal from British Columbia which takes about the same rate as Washington coal but which is mined in large measure by Orientals working for \$2 a day less than Washington union miners. An effort is being made to prevent an increase in coal land taxation in Kittitas County by a new assessment cruise. An offer has been made to voluntarily increase the valuation without a cruise.

WEST VIRGINIA

Logan coal operators are to open their own employment office at Charleston and W. A. Butler, of Lundale, will be placed in Charge. The office will handle only the employment situation for the Logan operators, as there is a constant demand for miners in the Logan field.

The Wheeling-Glenwood Coal Co. has been incorporated at Wheeling with \$500,000 capital by E. L. Peters and associates.

Title to 5,518 acres of coal land in the Boone County field, heretofore owned by the Laurel Coal Land Co., and located on Spruce Fork and Little Coal River has been taken by Pemberton Hurchinson and George McCull, president and vice-president, respectively of the Westmoreland Coal Co., of Philadelphia, which operates coal properties in the Irwin Basin of Westmoreland County, Pa. The large acreage in Boone County was purchased from the Chiltons, of Kanawha County, for a sum said to be in excess of \$600,000.

J. B. Clifton, one of the best-known coal men in southern West Virginia, having acquired the holdings of George Wolfe, president of the Atlantic Smokeless Coal Co., operating at Asco in the McDowell County field, has succeeded Mr. Wolfe as president of the company; Dr. J. Howard Anderson of Marytown, is vice-president; W. M. Black of Lynchburg, Va., is secretary and treasurer, and R. E. Brockman of Asco is general manager. The new president of the company is at the head of several large companies operating in the smokeless fields of southern West Virginia.

Coal loading records for a given week period were again shattered on the Chesapeake & Ohio during the week ending Oct. 13, when the output reached a total of 17,605 cars, equal to 880,250 tons. Of the total loadings it appears that between 60 and 65 per cent are originating in the Logan district. The remaining tonnage comes from the Kentucky, New River, Kanawha, Winding Gulf and Coal River districts, served by the Chesapeake & Ohio.

The Cap Smokeless Fuel Co. has purchased 850 acres of coal and timber land, including all equipment, houses and other buildings, owned by the E. G. Blume heirs of Fayette. The Fayette mine, which will be operated, is one of the oldest in the New River district, but during the past few years has been operated only at intervals. It was last operated by the E. G. Blume Co.

The Jamison Coal & Coke Co., operating in Pennsylvania and northern West Virginia, has liquidated \$150,652.08 of its first mortgage, 5 per cent sinking fund gold bonds.

Many mines in the New River field having no screening facilities are unable to operate. Owing to the fact that about the only grade now marketable is prepared coal several concerns in the New River district are preparing to equip their mines with screening facilities. Slack is going to the market below the cost of production.

The Fordson Coal Co., of Stone, Ky., have contracted with the Roberts & Schaefer Co. for the installation of a completely equipped steel tippie to be installed at its mine at Nuttallburg.

There has been an adjustment of the differences between consumers of power furnished by the Appalachian Power Co. and the company as to rates to be charged for power. About a year and a half ago coal companies using this power sought an adjustment of rates at the hands of the Public Service Commission of West Virginia. The commission, however, refused such a petition after a hearing lasting several weeks. The consumers took their case to the West Virginia Supreme Court. It is understood now, however, that there has been an agreement under the terms of which the case will be dismissed from the courts without prejudice, the power company settling all costs and expenses.

WASHINGTON, D. C.

The Department of Labor reports the adjustment late in October of four strikes of coal miners, with the return of the men to work pending conferences. Two of these strikes were at the Barnum Colliery, Pittston, Pa., and No. 6 Mine of the Pennsylvania Coal Co. of Pittston, both over working conditions and involved respectively 200 and 1,675 men. Another was that at the Central Colliery, Avoca, Pa., the cause being a union dispute and involved 600 men. The fourth strike was that at the Dana Colliery, Dana, Ind., the cause being given as railroad transportation. This dispute was referred to the Public Service Commission. Another such strike is still pending at the

mines of the Canaanville Coal Co. of Ohio, the cause and number of men involved not being given.

The U. S. Civil Service Commission announces open competitive examinations to fill existing vacancies in the positions of mine valuation engineer and assistant valuation engineer in the income tax unit of the Bureau of Internal Revenue, Treasury Department, Washington, D. C. The position of valuation engineer carries a salary of from \$3,600 to \$4,800 a year, and that of associate engineer from \$3,000 to \$3,600 a year. Applications for these examinations will be received by the commission up to and inclusive of Dec. 28.

Explosives sold in the United States during August, totaled 577,098 kegs of black powder, 4,463,830 lb. of permissibles and 19,779,355 lb. of other high explosives. Sales during the eight months ended with August were made up of 4,736,976 kegs of black powder, 37,768,814 lb. of permissibles and 151,694,228 lb. of other high explosives. The coal industry purchased 86.2 per cent of the black powder sold; 94.1 per cent of permissibles and 15.9 per cent of other high explosives.

Commissioner of Internal Revenue Blair has approved the ruling of the Solicitor of the Bureau in the case of a coal company holding that coal used in the manufacture of war materials is an article which contributed to the prosecution of the war and, therefore, buildings erected for the use of miners of such coal were "buildings constructed for the production" of that article. The effect of the decision is to allow the coal company in question its claim for amortization on miners houses built in 1918 to increase coal production as a war measure. The principle involved in this case is said to apply also to other facilities which may have been constructed between April 6, 1917, and Nov. 11, 1918, for the purpose of increasing coal production. Estimates have been made that several hundred coal-mining companies have failed to take a deduction for amortization in the years in which it is properly allowable, because of the fact that they were not aware they were entitled to such a deduction under the law. The National Coal Association calls attention of coal operators to the fact that failure to take a deduction for amortization in the years wherein it is properly allowable does not preclude the filing of a claim for refund or credit, based on a claim for amortization. Claim for refund or credit on any return, however, must be led within five years from the date on which the return was made. That period of limitation will expire on March 2, 1924. It is suggested, therefore, that coal operators who are entitled to amortization and have not made claim therefor must file a claim either for refund or credit on or before that date; otherwise, they will be barred by the Statute of Limitations. The decision of Commissioner Blair has been officially designated as A. R. R. 3920:11-29-1146 and will appear under that designation in the next issue of the Government's Service Bulletin.

CANADA

In the annual mine-rescue and first-aid meet under the joint auspices of the Rocky Mountain Branch of the Canadian Institute of Mining and Metallurgy and the Workmen's Compensation Board of the Province of Alberta, held at Blairmore, Alta., Drumheller took two first prizes, one for mine rescue and one for first aid, though the Crow's Nest Pass Coal Co.'s team from Michel Colliery tied with the Hygrade Coal Co., of Drumheller, in mine-rescue work. In the first-aid events Drumheller made 83.83; Lethbridge Collieries No. 1, 83.50; Bellevue, West Canadian Collieries, 82.83; Lethbridge Collieries, No. 2, 80.83; the International Coal & Coke Co., Coleman mine, 78; and the two Crow's Nest Pass Coal Co.'s teams from Michel and Coal Creek Collieries, 76.50 and 67.83 respectively. Four teams of Boy Scouts had a separate contest, and one ladies' team, obtaining a score of 82.83, was awarded a prize. In the mine-rescue contest the Crow's Nest Pass Coal Co., Michel Colliery, and the Hygrade Coal Co., Drumheller, each obtained 91 per cent; Crow's Nest Pass Coal Co., Fernie No. 2 team, received 90.53; Brazeau Collieries and West Canadian Collieries, Bellevue No. 3 team, each 90. There were in all twelve teams entered in the mine-rescue contest. Medals were given to both the teams making the top score.

The bituminous-coal mining interests of New Brunswick are manifesting keen interest in the Employers' Association, which is being formed to represent the employer in business with the Provincial Workmen's Compensation Board. The chief difficulty

to the organization is the reluctance of the board to countenance the birth of the association, which under the law, must be approved by the board. The efforts to form the association are the fruits of the present and past policy of the personnel of the board which has sought to penalize industry in maintaining the board. C. J. Cell, manager of the Minte Coal Co., represents the coal mining interests on the provisional executive of the Employers' Association.

Michael Dwyer has resigned as mechanical superintendent of all of the Scotia Co. Sydney Mines, N. S., and will devote his time to the Indian Cove Coal Co., of which he is managing director. Mr. Dwyer has been connected with the Scotia Co. for a number of years in various official capacities.

The Seagram-Fawcett Coal Co., Ltd., of Waterloo, Ont. has been incorporated with an authorized capital of \$100,000. The provisional directors are Edward F. Seagram, William J. Fawcett and John Ferguson.

The Dominion Coal Co., of Glace Bay, is installing two Marcus screens in its new steel tippie.

The Milnes Coal Co., Ltd., of Toronto, has increased its capital from \$250,000 to \$500,000.

James B. McLachlan, former secretary of the United Mine Workers district 26, convicted in the Supreme Court on a charge of seditious libel, was sentenced on Oct. 31 at Halifax, N. S., to two years imprisonment. The charge arose out of a letter circulated among the locals of the union accusing the provincial police of atrocities in dealing with the striking coal miners. The charge of conspiracy brought against his colleague, Daniel Livingstone, president of the organization, has not yet been tried and he is out on bail. At Sydney the grand jury has returned a true bill against John Macdonald of Toronto, also charged with seditious utterances.

The commission appointed to inquire into the Cape Breton steel workers' strike has been holding preliminary meetings to consider the scope of the investigations, and began the taking of evidence at Sydney, N. S., on Oct. 31. It has been decided that if it should appear that there is a relationship between the steel workers' strike and that of the Cape Breton coal miners the latter will be included in the inquiry.

A mining company in the union field of Alberta won the right to hire whom it would without union interference under a decision recently handed down by a conciliation board appointed by the federal Minister of Labor. The decision is considered of great importance and is unprecedented in Canada. In July, when the Hygrade mine at Drumheller reopened after a shutdown, the mine manager declined to re-employ James Conroy, a union miner. The managing director of the company also declined. Conroy claimed they should be compelled to give him employment under the "preference of employment" clause of the working agreement which reads: "In case an employee is thrown out of employment, unless discharged, he shall be given preference over new men in other mines in the same camp operated by the same company." The company held that, since it had but one mine, it could decline re-employment to former employees even though they had not been discharged previously. The conciliators supported this position.

British Columbia's coal production for the month of September totalled 181,634 tons, a drop as compared with the previous month of 40,662 tons. Of the total output the Vancouver Island mines were responsible for 121,880 tons, approximately 67.1 per cent, which is 14,067 tons under the production of August. The Nicola-Princeton mines produced 18,978 tons, a decrease of 2,613 tons in comparison with the output for August and about 10.4 per cent of the total production. The mines of the Crow's Nest Pass district produced 40,776 tons, which is 23,982 tons under the August figure and some 22.5 per cent of the total for the province. All the Vancouver Island mines show a decline with the exception of the Canadian Collieries (D) Ltd., Comox mine, which has an increase in comparison with August results of 689 tons and Messrs. King & Foster, Old Wellington mine, which shows an increase of 7 tons.

Output of coal from Canadian mines during July amounted to 986,400 net tons, a decrease of 25 per cent from the tonnage for the previous month and 14 per cent from the average for the month of the three preceding years. The output for the month showed decreases of 435,000 tons in Nova Scotia, and 4,000 tons in New Brunswick. In Alberta there was an increase of 106,000 tons, in British Columbia 6,000 and in Saskatchewan 2,000 tons. The cumulative output from all mines for the seven months

of 1923 amounted to 9,717,000 tons, an increase of 20 per cent over the preceding three-year average for the same period. Comparison of the July and June figures covering the importation of coal from the United States and Great Britain showed a decrease of 5 per cent. July imports amounted to 2,445,000 tons, while in June 2,562,000 tons was brought in. The July importations this year were 58 per cent greater than the preceding three-year average for the month. Importations from Great Britain during the month totaled 60,900 tons. Total importation of all coal for the seven months of 1923 was 12,648,000 tons, an increase of 53 per cent over the three-year average for the period. The imports of anthracite for July totalled 495,800 tons. This was 2 per cent less than in June but 37 per cent higher than the three-year average for the month. Anthracite imported from the United States amounted to 474,200 tons while 21,600 tons came from Great Britain during the month. The total amount imported during the seven months of 1923 was 3,187,600 tons, an increase of 44 per cent over the three-year average for this period. The exports of Canadian coal for the month of July were 28 per cent less than in June. The quantities were: July 73,000 tons, June 101,400 tons. Comparison of the July exports with the preceding three-year average showed a decrease of 67 per cent.

Obituary

Nathaniel Shanklin, 81, one of the men who developed the Grundy County Coal Co., died at his home in Trenton, Mo., Oct. 26, after a lingering illness. He also had been identified with other business enterprises of Trenton, including general merchandising, grocery and feed and fuel, but his greatest success was with the coal company.

James Russell Fitzer, head of the J. R. Fitzer Coal Co., a jobbing concern in the Citizens Savings & Trust Building, Columbus, Ohio, died suddenly Oct. 31 from heart trouble. He came to Columbus six years ago to become salesmanager of the Sunday Creek Coal Co., which position he held up to two years ago. He leaves a widow, two sons and a daughter. One son, John Fitzer, was associated with him in business.

Edwin Ball, age 65, general manager of coal and ore mines for the Tennessee Coal, Iron & Railroad Co., died suddenly at his residence in Birmingham, Ala., Oct. 27. Mr. Ball came to the Birmingham district a number of years ago from the northern ore fields and had been manager of mines for the Tennessee company during his entire residence in the South. He was an able official and had many friends among the employees of the company. He was also prominent in civic affairs and club circles. Mr. Ball was born in England and came to this country at the age of sixteen.

Association Activities

The question of ore equitable freight rates on smokeless coals produced in the Pocahontas, Tug River, New River and Winding gulf fields, as discussed in a recent meeting of the **Smokeless Coal Operators Association of West Virginia** at New York is being brought to the attention of consumers in New England and other states along the Atlantic. It is being pointed out to the consumers that an adjustment of rates is important if consumers are to obtain soft coal when it is needed and particularly during periods of hard-coal shortage. If all-rail rates to the Atlantic markets were more equitable, it is pointed out, it would be possible to establish a large and steady market and thus supply the demand. As stated at the recent meeting at New York coal can be shipped from the smokeless fields to Chicago for \$3.27 a ton and yet the same amount of coal shipped to New York, which is twenty miles nearer takes a rate \$2.75 per ton higher. Not only is that true but the freight rate to Baltimore and Philadelphia is higher than the rate to Chicago, although the distance is much shorter.

The Van Dorn Electric Tool Co., Cleveland, Ohio has issued a page folder illustrating and describing its **Electric Glue Pot**.

The Reliance Electric & Engineering Co., Cleveland, Ohio, has available for free distribution a 51-page paper by its chief engineer, A. M. MacCutcheon, entitled "**Anti-Friction Bearings in the Steel Mill**." This was presented at the fifteenth annual convention of the Association of Iron and Steel Electrical Engineers and is written from such a standpoint that it is of general interest to users and designers of machinery and power equipment in other industries.

Publications Received

Timbering of Metal Mines, by E. A. Holbrook, Richard V. Ageton and Harry E. Tufft, Bureau of Mines, Washington, D. C. Bulletin 215. Pp. 72; 6x9 in.; illustrated. This manual is intended chiefly for the practical miner or small operator.

Traffic News

A complaint has been filed by the Hannibal Shippers' Association against the A. T. & S. F. Ry. attacking rates charged on coal from Illinois mines to Hannibal, Mo. The complaint stated that preferential rates had been allowed by the defendant carrier to St. Louis and other points which are in direct competition to the members of its association, pointing out that these preferential rates are in violation of Section 3 of the Interstate Commerce Act.

Railroads of the United States on Oct. 15 had 10,509 locomotives in need of repair, 16.4 per cent of the total number on line, according to a report by the Car Service Division of the American Railway Association. This was an increase of 686 over the number in need of repair on Oct. 1, at which time there were 9,823, or 15.3 per cent. The railroads on Oct. 15 had 2,487 serviceable locomotives in storage where they are being held until traffic conditions necessitate putting them in service. During the first 15 days in October 19,323 locomotives were repaired and turned out of the shops.

Freight cars in need of repair on Oct. 15 totaled 155,637, or 6.9 per cent of the total number on line, according to reports filed by the Car Service Division of the American Railway Association. This was an increase of 4,305 over the number in need of repair on Oct. 1, at which time there were 151,332, or 6.7 per cent.

The Interstate Commerce Commission has refused to suspend the new tariff increasing freight rates on Utah coal. The petition for rehearing is still before the commission. The commission order was effective Oct. 15, and it was explained the request for suspension had been filed too late, as at least ten days' notice and preferably twenty, before the tariff becomes effective was required. The order increases rates on Utah coal to points west of Mountain Home.

Volume 24

NEW YORK, NOVEMBER 15, 1923

Number 20

The Anthracite Rate Hearings

WHAT implicit faith the public has in its public agencies! Here is the Interstate Commerce Commission, acting on the demand of the Coal Commission, making diligent inquiry into freight rates on anthracite. The Commerce Commission has gone to the ends of and nary a consumer at hand to protest these rates. the hard-coal consuming earth, Pittsburgh on the west and Vermont on the north, holding hearings and finding it necessary veritably to drag the witnesses in who would say a word on the supposedly liveliest topic in the East.

But if the affair has dragged so far, the broadening of the scope of the investigation to include rates on bituminous coal, substitutes for domestic sizes of anthracite, as was done last week by the Commerce Commission, will liven things up. If the hard-coal consumers are passive as to the possibilities of the situation, the soft-coal producers are not, and it is certain that an effort will be made to get all-rail rates into New England and New York on such recognized substitutes as smokeless coal that will boom that business.

Central Pennsylvania, also a producer of high-grade low-volatile coal, has, as a whole, neglected in the past the domestic trade on the theory that to seek to compete with anthracite were hopeless. These producers are now given incentive to enter the lists thus opened by the commission. There will also be opportunity for the commission to apply its general theory of favoring short hauls and frowning on the long haul as wasteful of transportation. Smokeless coal, heretofore confined to water haul to New England, is knocking at the door for an all-rail rate that will permit it to enter this rich market for household coal with a product that has not been degraded by many handlings over docks.

No Wage Cuts

IT IS time for some gloomy pessimist to step right out in front and put a great big broad chalk mark on the wall for the non-union coal operators. One after another the strong associations are lining up definitely and firmly on a policy of holding wages to the present level. Hazard took that stand some time ago. The entire Smokeless field has put itself on record against wage reductions. Logan put it to a vote of the men, as it were, and came to the same conclusion. Some of the others are as yet a trifle uncertain. Now is the time to make it unanimous.

The unanswerable argument dictating this policy is that no reduction of wages that could reasonably be made will put the cost down to a point that will sell more coal in the markets of today. Spot-coal prices have descended well below the contract-price levels and even below average cost. Any individual advantage arising from a sharp drop in price is certain to be tem-

porary. The exception is proving the rule, for some local wage reductions are proving embarrassing to the operator, who is now looking for an excuse to put them back up.

From a broad standpoint of policy in industrial relations as well as of selling, this action of the non-union operators is well advised. It serves to point out to union men—operators as well as mine workers—that the non-union men are not black, as so often painted. There is a proper time to raise or to lower wages, when you are free to do so. The non-union fields have well judged that this is not such a moment. Conditions are far different now than in the fall of 1921, even though a union wage contract expires the following April.

Furthermore a policy of no wage reductions answers the gloomy critics who have imagined that the sole interest animating the non-union operator is to drive a wedge in between the operators and men in the organized fields, to foment strikes and to profiteer while the union fields are prostrate, whether by reason of strike or because of high and ungovernable costs.

Recapturing the Usufruct

THERE is nothing novel or new in the proposal of the Coal Commission to impose a graded tax on the anthracite producing industry as the one corrective measure to give the hard-coal consuming public "a share in the good fortune of the low-cost, high-profit operator." The excess profits tax of war days was that kind of a measure with the essential difference that it applied to all business alike, and was not assessed against a single industry or class. This plan was suggested by the commission in its summary report of September and repeated in that on investments and profits in the anthracite industry, issued last week.

As a plan it must, first of all, be viewed as a compromise measure. The painstaking and thorough investigation of the commission into this aspect of the hard-coal business disclosed wide variations among producers in the margin between cost of production and the selling price of anthracite. Whereas, in 1921, thirty-nine producers having about seven per cent of the total output lost money, thirty-three per cent of the tonnage was sold with margins ranging from 1c. to 50c. per ton; 52 per cent from 50c. to \$1 per ton; and nearly eight per cent between \$1.50 and \$1.75 per ton. The differences were even more pronounced in the first quarter of 1923, when three-quarters of the total anthracite was sold at margins from 80c. per ton upward to \$3 and over. No one would think, however, of that as a feature characteristic of anthracite, for it is inherent in all business.

It is plain enough the commission considered that some of the companies garnered too much profit. See-

ing that 278,000 tons out of more than 18,000,000, or 1.5 per cent, brought the producer and seller \$3 or more per ton in the first three months of this year the layman, the general public, will quickly come to the same conclusion. It might have the same opinion of the average margin for all in that three-months' period, namely \$1.19 per ton, as compared with 54c. per ton in the year 1921.

It is pointed out in this report that margin is not profit, for against it are to be charged federal taxes and interest on borrowed money before the amount available for the owners of the property is known. Nevertheless the margin is an index of profits, and since the commission was not able to name the profits in terms of percentage on investment, the public must look to the figures of margins as a basis for judgment, tempered of course by individual opinion as to whether the industry is entitled to a return on investment measured by present value of the properties and the unmined coal, as measured by original cost, or by some method that gives a figure between these extremes.

But by whatever process of reasoning, before one comes to the conclusion that some of the anthracite producers are taking too great a profit, as the Coal Commission has judged, and following that with the conclusion that the "low-cost, high-profit" producer must be forced to forgo a portion of his gains, one is forced to accept the philosophy that the production of anthracite is a public utility, charged with public interest in a legal as well as economic sense, before that industry can be singled out for a graded income tax on differential profits.

There are other questions as to the legality of such a scheme. The production of anthracite is an intrastate business, hence how can there be a federal tax on income? There is some doubt also whether the present laws of Pennsylvania would permit a state income tax of the nature proposed. But why compromise? If the production of anthracite is a public utility, with some operators making too much profit, why not go the full distance and give the consumer directly the benefit by price regulation or even nationalization of the mines? The public, as did the Coal Commission, balks at this extreme. Price regulation and federal operation, both promise to increase rather than lower costs and prices.

The Coal Commission notes that a graded tax on income would not lower price, but it did not comment on the possibility that it would raise the average cost to the consumer. There are two price levels for hard coal, the conservative one of the "railroad" companies, representing 70 per cent of the whole, that keeps the average down, and the free market price of the independents that reaches higher levels at times of peak demand. What incentive to the large producers to restrain their prices in such a market as that of this fall, if the public is satisfied to pay the price and take a rebate in general taxes?

There is much more to the commission's report on Investments and Profits in Anthracite Mining than its recommendation for a graded tax, though that is its remedy. The report recommends current publicity of all data on costs, prices and profits, and urges the consumer to turn to substitutes if he would lower the price of anthracite. In its assembly of facts, presentation and summarization this report is well above the average of what the Coal Commission has produced. A very difficult subject has been well handled.

Pinchot's Sixty Cents

GETTING a 10-per cent increase in wages through for the anthracite miners was child's play for Governor Pinchot compared with the task of making good on his boast to force the distribution machinery of the industry to absorb that increase in cost. The Governor's latest drive in this direction has the elements of simplicity in every meaning of the word. In short he called the operators to Harrisburg and asked them to agree among themselves and with him to refuse to sell or ship anthracite to any dealer, or to any wholesaler who would ship to any dealer, who charged the public *more per ton than for the same coal a year ago*.

Aside from the fact that the dealer might righteously resent being made the goat for the whole cost of the Pinchot excursion into labor politics, there is the very practical fact of liability for conspiring on the part of any operators who engaged in such an undertaking. Governor Pinchot promised that his Attorney General would give the operators an opinion that would demonstrate that no law could or would be violated by such an agreement, but his Attorney General has not had time during the past month to write it out. Meanwhile the operators are proceeding on the advice of their own legal counsel.

It is hard to believe that Governor Pinchot is really serious in making such a proposal. He may be a practical politician, but he cannot be a practical business man to ask the coal producers to engage in such a doubtful enterprise—to further his political future. The publicity given out passes the buck to the operators, so the Governor may be satisfied.

The Railroads Deliver

THERE may be those who regret the absence this autumn of the usual and normal coal-car shortage and seasonal coal-price flurries. If so they are an insignificant minority. The country is rejoicing in the achievements of the railroads in the year 1923. When early in the year the railroad executives announced that every indication pointed to an unprecedented demand for transportation in the period to follow and that they were going to meet that demand, the popular thought was: Interesting if true.

It was and is true and as pictured to the railroad presidents assembled in New York last week, it was little short of dramatic. The achievements in rehabilitation and in handling traffic the past year have set new records. Emerging from the strike of 1922 and facing a huge demand with an undue proportion of equipment in poor repair and with weakened credit, the railroads have come forth victorious in all save one respect—their earnings are yet below the minimum named by the Interstate Commerce Commission as representing an adequate return.

The railroads are now asking that they be given yet another year in which to demonstrate what private ownership can do. They want the Transportation Act to have a longer life before it is tinkered with. They are asking, in other words, that Congress leave them alone this winter. The railroads have concluded that this Transportation Act that looked so heinous to them three years ago is after all pretty good. Every encouragement should be given the railroads to work out their own destiny under this law, in view of the splendid performance of this year. None can but agree that 1923 promises well for 1924.

Destruction of Anthracite Breakers Proves Need of Fire-Prevention and Fire-Fighting Equipment

Recent Conflagrations Entail Heavy Losses—Use of Steel and Concrete in Construction Materially Reduces Fire Hazard—Prohibit Smoking and Use of Naked Lamps—Description of Spray System in Coal Breaker

BY HAYDN HAMMOND

Mechanical Department, Lehigh Valley Coal Co., Wilkes-Barre, Pa.

DUE to a number of large financial losses experienced by several coal companies in the anthracite field within the past year or two, fire protection in anthracite breakers of timber construction is absorbing more thought and study than in the past. The Susquehanna Coal Co. probably suffered greatest, three breakers having burned to the ground within a few months, namely: the William Penn, at Shenandoah, Pa., and Nanticoke Nos. 5 and 7, at Nanticoke, Pa. The Hudson Coal Co. lost the Laffin breaker, at Laffin, Pa., and the George F. Lee Co. lost the Chauncey breaker, at Avondale, Pa. The latter was completely destroyed within three or four hours after the fire was discovered.

These recent heavy losses give conclusive evidence of urgent need for more consideration of the fire hazard and the adoption of efficient fire prevention and fighting methods and apparatus. Coal breakers are an easy prey to flames because of the very nature of their construction as well as because of the fine particles of coal dust that are continually floating in the air, the oil- and grease-soaked timbers and floors.

A prime essential is protection against the possibilities of fire. This involves due consideration of the location, layout, construction, and operation of the

breaker as well as the enforcement of certain fire-prevention rules and regulations.

First of all the breaker should be erected far from other buildings that are inherently susceptible to fire or that may even cause fire to be carried in their normal operation. Conversely, it may be said that all other structures should be located sufficiently far from the breaker so as not to set it on fire. Obviously the powder house should be located in some remote place on the property, as is usually the case. However, too little consideration sometimes is given to the location of the boiler house, blacksmith shop, oil house and warehouse.

ELECTRIC PLANTS SHOULD NOT BE NEAR BREAKER

Where electric power is used it is foolhardy to mount the outside lightning arresters and switches on or near the breaker structure, as is frequently done. Transformer substations, switching towers and direct-current converting equipment should be located at some distance from the coal breaker. More attention would no doubt be given to the location of this equipment if the designing engineers were to be called upon to operate the apparatus and not only be impressed with the difficulties experienced in keeping the equipment free from dust but also with the fireworks that are set into action on heavy overloads or during lightning storms. Then again, fire practice and fire fighting is always more dangerous and difficult when

NOTE—Headpiece shows one of the most recent collieries. Many of the older plants, which it does not pay to rebuild, being made of timber and not concrete, glass and steel, need protection such as this article describes.

hampered by treacherous power lines and switching equipment being nearby.

The layout of the breaker structure should be such as to prevent the spread of fire. Steam-locomotive tracks should be laid out only through those sections of the breaker which are concreted or similarly protected from fire from the sparks thrown by the locomotives.

Construction materials such as steel and concrete greatly reduce the fire hazard. Sheet-steel or asbestos-covered rooms should enclose all apparatus which is susceptible to fire but which must be located in the breaker structure. Oil switches and in fact all power switches should preferably be located in fireproof buildings remote from the breaker and controlled by automatic start and stop pushbuttons located at the motors and other convenient locations. All wiring should be enclosed in conduit, motors should be provided with conduit connection boxes and all electrical equipment should be thoroughly painted with a waterproof insulating varnish to prevent, as far as possible, deterioration of the insulation, which may cause flashes from grounds and short-circuits. Steam lines, wherever used, should be covered with pipe covering for the double purpose of preventing heat losses and fire.

EQUIPMENT SHOULD BE TESTED FREQUENTLY

Fire-spray systems, augmented by fire buckets, and fire-alarm systems should be installed and tested frequently. Rules against smoking and the use of naked lamps should be rigidly enforced. Fire-alarm boxes should be marked with red lights and when the breaker is idle all other lights should be extinguished so as

to make any fire more easily visible to the watchman while on his rounds. Workmen doing repair work should be provided with extension electric lamps and battery lamps of suitable candle power and capacity to give sufficient illumination for working in the darkest corners. The batteries of these lamps may be readily strapped to the workman's belt and the lamp carried on his cap or in his hand, enabling him to move from one location to another over and around screens, chutes, jigs, etc., without dragging along an extension cord.

The fire-spray system installed in the Prospect breaker, located in Wilkes-Barre, Pa., was originally put in service in 1915. A reservoir of 200,000 gallons capacity furnished the fresh water supply under an entrance head to a steam-operated 28x16½x32 duplex pump. The suction pipe was 12 in. in diameter. The pump discharged into a 12-in. cast-iron line connected to a 12-in. main riser pipe in the breaker. At the various floors and platforms and under the roof, laterals were run to approximately seventy spray heads, so located that the entire breaker could be wet down. The amount of water was limited to the safe pump speed, which gave a capacity of approximately 1,600 gallons per minute. On account of some breaker changes it was found necessary recently to add additional laterals and spray heads requiring increased pump capacity up to 2,500 gallons per minute, which the original pump could not deliver at a safe speed. It was therefore decided to replace the duplex pump by an 8-in. single volute centrifugal pump manufactured by Barrett, Haentjens & Co. and driven by a type C. I. Terry steam turbine.

The pump has a capacity of about 2,500 gallons per minute against a total head of 125 ft. at 1,800 r.p.m. The driving unit is equipped with a throttling governor, an emergency governor and water-cooled bearings. The wheel is made from a single forging of special composition steel, and the semi-

FIG. 2—SPRAY HEAD USED IN PROSPECT BREAKER

Some of these spray heads are installed in an inverted position, depending upon the conditions and direction in which the water is to be thrown.

FIG. 1—PUMP AND TURBINE UNIT FOR FIRE SPRAY SYSTEM

The pump has an entrance head of 10 ft. and in 77 seconds can discharge the equivalent of ten fire-hose lines from ninety-eight sprays.

FIG. 3—PIPE LAYOUT SHOWING LOCATION OF FIRE SPRAYS

These views show how the sprays are scattered throughout the breaker and on the conveyor lines. Note that many of the sprays are located in the upper part of the breaker, the open structure inside the breaker readily permits the water discharged at the higher elevations to wet down the lower sections quickly.

circular buckets or pockets are milled from the solid metal. The blades have large clearance and are further protected by the projecting rims at the sides of the wheel, which would take without damage any rubbing that might occur if clearance became reduced. The turbine is of the radial-flow type and is run non-condensing. The steam conditions at the colliery average 110 lb. gage pressure.

The pump is located so as to have a 10-ft. entrance head from the same reservoir through 10-in. suction pipe and discharges through an 8-in. opening to the old spray system. The 12-in. main is 360 ft. to the foot of the breaker and the riser in the breaker is 138 ft. There are approximately ninety-eight spray heads in the building, of which some are upright, as illustrated, and others the reverse, depending upon the location and conditions for which they serve.

SYSTEM EQUALS TEN LINES OF FIRE HOSE

The system will throw a quantity equal to ten lines of fire hose throwing 250 gallons per minute each. The regular standard fire equipment, such as lines of hose, fire pails, water barrels, etc., serve as additional protection.

A bypass on the pump discharge line permits running the pump daily, without flooding the breaker, to assure its being in operating condition at all times. In a recent test from starting until water was discharging through all sprays took 77 seconds. The

centrifugal pump was selected in preference to a straight-line duplex pump as it has less moving parts requiring attention and it also eliminates valve and packing troubles.

STEEL DISPLACES TIMBER IN EUROPE.—Owing to the scarcity of timber, various substitutes are being employed in European countries for mine props, says George S. Rice in his report to the Director of the Bureau of Mines relative to his recent trip to Europe. Steel props and steel arches are being extensively used to uphold mine roofs. In Belgium, mine shafts, in wet, "running," ground, are being largely constructed by the freezing process, in which, through the medium of refrigerated brine forced through pipes surrounding the area to be excavated, the ground is frozen and made easier of excavation. Shafts more than 600 ft. deep have been sunk by this method.

PROFESSOR VLADIMIR KARAPETOFF, of the School of Electrical Engineering, Cornell University, has been awarded a prize of four thousand francs by the Montefiore Foundation of the University of Liège, Belgium. The award was made for his kinematic computing devices of electrical machinery, described in the technical press during the last three years. A committee of five Belgian and five foreign members, which makes these awards, has characterized this work as an expression of a "new idea which may lead to important developments in the domain of electricity."

British Coal Industry Opens Doors to American Observer

Letters from Officials and Industrial Leaders Prove Open-Sesame—Reassuring Credentials Elicit Frank Thoughts on Pressing Problems

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

KNOWING that the British have been mining coal for five centuries and that they have developed a highly stable industry, the editor of *Coal Age* suggested to me that there should be a few leaves, at least, that the bituminous-coal industry in this country could take from the book of British experience.

Mr. Leshar gave me the assignment in the hope that I could learn something that might be helpful to the industry here to get on a better basis. He did not choose me for that undertaking because of technical knowledge of coal production or distribution. I have dug no coal. My name never has appeared on the payroll of a coal-mining company.

The real truth of the matter is that Mr. Leshar did not want the British mines examined. He did not want statistics compiled nor costing systems analyzed. He wanted someone to go abroad who would search out the men in the coal trade there having the rather rare faculty of being able to survey and appraise the industry as a whole. He wanted someone who could see scores and scores of such men so that we could obtain a good cross-section of opinion. He knew that the men who have spent their lives in the British industry have at their tongues' ends more accurate information about it than could be compiled in a year by twenty American experts making their own first-hand examinations. All that he wanted to do was to send a news gatherer who had some conception of the troubles which afflict the American industry to talk with British coal men and to ascertain how they have met those problems or have prevented them from becoming acute.

I had the advantage of long experience in Washington, where one man is expected to keep an eye on 435 Congressmen and 96 Senators, as well as to keep abreast with the doings of some 300 executive and other establishments and agencies. Such experience tends to develop an ability to flit quickly from flower to flower in the search for news and opinion. Experience in Washington has educational value in that the news gatherer here must learn to separate wheat from chaff in opinion. For these reasons the articles which I expect to write will contain no opinion of my own. I will attempt to reflect as accurately as it is within my power the many interesting things which were told me and shown me by those engaged in the production and distribution of coal from British mines.

I set out with some important assets in the form of letters. One was from the Secretary of State. Then I had a letter from Commerce Secretary Hoover, which I displayed at the slightest excuse, as I found it was particularly effective in paving the way into confidence of those on whom I called. John Hays Hammond, at that time chairman of the Harding Coal Commission, took the risk of giving me a blanket endorsement. In addition he gave me a letter to Post

Wheeler, counsellor of the American Embassy in London, who reacted by authorizing me to refer to the Embassy anyone suspecting me of muckraking proclivities. This proved to be an important anchor to the windward, as in London they are inclined to credit any American newspaper man of an uncanny ability in the twisting of prosaic facts into sensational articles. Dr. George Otis Smith gave me a letter to his intimate friend Sir Richard Redmayne, chairman of the Imperial Minerals Resources Bureau, who proved to be a wonderful source of information and worth-while opinion. F. R. Wadleigh, then Federal Fuel Distributor, gave me a sheaf of letters. He once was the London representative of an American coal company. He knows the men there who have ideas and who have the faculty of concise expression.

Julius Klein, director of the Bureau of Foreign and Domestic Commerce, gave me letters to the department's commercial attachés. They were more than perfunctory letters of introduction, but I doubt if they obtained any special favors for me. From what I saw at the foreign offices of the Department of Commerce, the members of their staffs go to any amount of trouble to be helpful to all comers. In addition, I had various letters from several of the American coal companies who have representatives in London or Paris.

BRITISH COAL INDUSTRY WIDELY DISTRIBUTED

These credentials had the effect of opening any door that I could reach. Unfortunately, my time was so limited that I could not make all of the calls I desired. Not only is the production of coal well scattered over England, Scotland and Wales but the men connected with the industry in London are well distributed over the 600 square miles which the city occupies.

Both at Cardiff and at Newcastle I was given the privilege of the floor at the exchanges. This made it possible for me to question a much larger number of men than would have been the case otherwise. I found no tendency among all those with whom I talked to be reticent. My greatest trouble was in keeping them from interviewing me. They were so anxious to learn just how we do things that it was difficult to keep them talking on the things I wanted to learn about. They are more insistent, however, than the average American in satisfying themselves whether or not an interviewer is likely to make constructive use of the information which they furnish. Reassured by my credentials and by my local sponsors, I believe they acquainted me frankly with their real thought on the problems of their industry, but in nearly every instance they would exact the promise that they were not to be quoted.

[Next week Mr. Wooton will begin the recital of his experiences abroad.]

Commission Proves That

Machine Loading Reduces Mine Cost 30 Per Cent*

U. S. Coal Commission Investigator Finds Machines Loading
45 Tons an Hour, Even Though Idle 40 Per Cent of Time—
He Compares Machine and Hand Loading in Same Mine

THE statement already made that the cost of coal at the mines may be reduced in many cases by 30 per cent is not theory but is based on a thorough analysis involving detailed time studies of the operation of loading machines in several mines with access to the confidential records of the operating companies. The figure is conservative because it takes but small account of the supplementary savings that will accrue from extended development of the machine.

I and my associate industrial and mining engineers expended several days studying loading machines at work in two mines and made time studies of the work in a third. The general plan of operation with the large loaders is as in Fig. 1, which shows in outline the general type of several designs of loading machines. The head of the machine, which in some types is on a truck running on the track and in others on a caterpillar tractor, and in some cases has on the floor line a cutting machine, is run ahead, thus assisting the lower conveyor to collect fine coal and lumps. This conveyor, which consists essentially of a chain with suitable flights running on an inclined trough, is fed in some machines by separate clawlike arms.

The upper or discharge conveyor of the machine running on a vertical plane, with the emptied flights below the full ones, receives the coal from the lower one and discharges it into mine cars. As the pile of coal is taken away, the head is moved sidewise, or forward, into fresh coal, either by the aid of jack posts as mining machines are moved, or else by the mechanism of the loader itself. One man operates the machine and another may be required to assist the haulage motorman in adjusting the discharge conveyor to the car.

FILLS A FOUR-TON CAR IN THREE MINUTES

For the large-capacity loader, which fills a 4-ton car in two or three minutes, the locomotive stays with the car and hauls it out to the empty track as soon as it is filled, whence it is taken in trips of a few cars each, by another locomotive. As soon as the room is cleaned up, the loader, under its own power or hauled by a locomotive, is taken to the next room. The room which is vacated is then ready for the machine cutter. This is followed by the electric drill and shot-firing, and by the cleaning up of any slate that may have fallen. Under good conditions a loader may load the same room twice in a single shift.

A typical day's work of a large and a small loader is shown in Fig. 2. Only the delays due to shifting the machine from one working place to the next are shown by the breaks in the line, the time waiting for cars between individual loads being included in the general

line of the curve. Nevertheless the length of these waits is shown in detail for a typical period in Fig. 3.

In our discussion 400 tons is assumed as a conservative output for the large loader, although this is slightly higher than is shown in the table or diagram, because as such work becomes more nearly a routine and the haulage becomes still better adapted to rapid loading less time will be lost. Besides this, in the days observed, delays occurred due to cars leaving the track or to lack of adequate power, for which in operation there should be no excuse. Furthermore, records of the company show average loading for a period of two weeks at a rate as high as selected, with occasional days in which it was greatly exceeded.

FIG. 1—DIAGRAM ILLUSTRATING LOADING METHOD
By the use of two conveyors the desired flexibility between points of loading and of discharging is attained. Most machines are modifications of this principle.

Reference has been made to large recovery with a large loading machine. The machine works so fast that it is possible quickly to clean up pillars and stumps clear up to the breaking line, giving the roof far less time or opportunity to fall than in hand loading.

A Day's Work of a Loading Machine.—The records of a day's work of a loader in Tables I and II are from actual detailed job analysis covering in each case an entire day of continuous observation with a stop watch. The results of one of these days of a loading cycle for a large and small machine also are shown in graphic form in Figs. 2 and 3, previously described.

ALL THREE LOADING MACHINES DO EQUAL WORK

Studies of the large machine were made by our engineers in two different mines of the same company, one loading machine in the first mine and two loading machines in the second. All these machines were of the same type, one of them, however, having been in operation for five years, at first experimentally and intermittently. Note particularly in the table the uniformity of operation of the three machines. As will appear in subsequent discussions, the operation is normal and representative of regular, continuous daily production.

Examining further the tables for the large machine we note that the time of loading a four-ton car averages 3.2 minutes. Fig. 3 shows a minimum loading time of less than 2 minutes. In one of the mines a number of four-ton cars were loaded in a little over one minute each. Including delays waiting for cars, etc., the total gross loading time per car averages 5.6 minutes. The average tonnage per machine in eight

*Second installment of Report on "Underground Management in Bituminous Mines," made by Stanford E. Thompson and associates to the U. S. Coal Commission. The first section appeared in *Coal Age*, Nov. 8, page 691, and was entitled "Coal Commission Suggests Ways of Operating Mines That Would Lower Cost." Other installments will follow later.

hours for the day's observation is 352 tons (of 2,000 lb.), but out of the 480 minutes in eight hours the machine was loading coal 270 minutes, or 56 per cent of the time, and the rest was taken up in changing cars, moving loader, and incidental delays as indicated.

It is evident that with more continuous operation there will be a large increase in the production. If the idle time were reduced to, say, 20 per cent, which is certainly a fair possibility with well-designed transportation, the output would be increased to 550 tons in eight hours.

Instead, therefore, of the 400 tons taken as a conservative average, we may expect a working rate eventually for the large machine of at least 500 tons per eight hours. From the relation of working to waiting time it is evident that attendance upon the loader and the planning of the mine development to meet the needs of the loader, need for maximum production and economy more careful treatment than they are receiving at present. As the loading machine has outdistanced hand shoveling so must control of the operations, the apparatus, and equipment go beyond present methods by which hand loading is planned, controlled and aided mechanically.

TABLE I—ANALYSIS OF DAY'S WORK OF LARGE LOADERS
Loading Rates and Tonnages

III.....	3.3	5.8	8.2	0.9	1.5	0.1	2.5
Average.....	3.2	5.6	7.2	0.8	1.4	0.3	2.5

The time lost in waiting for cars must be reduced by improvements in haulage methods. That lost in moving the loader can be lowered by modifying the manner in which the mine is developed. Nor is that time now lost through miscellaneous delays incapable of being saved, for better standardization and maintenance of equipment will ultimately reduce it.

The data on the small machine given in the Table II are taken from an experimental run of fourteen days conducted by the mining company and from observations made by company officials and representatives of the manufacturers of the loading machine. The important values were checked approximately by our engineers on their visit to the mine. From the observations we selected three of the best days' runs, as it is evident, with machine loaders as with all machinery, that continuous operation smooths out defects and tends to increase the average production to or beyond the maximum in the first experimental runs.

With the small machine the percentage of delays is lower—an average of 35 instead of 44 per cent—but with it more time is lost waiting for cars—an average of 1.9 minutes between loadings instead of 1.4 minutes—showing less efficient haulage in the mine with the small machines. Assuming 20 per cent for delays, the same figure as selected as fair idle time with the large machine, the average capacity of the small unit would become 150 tons in each eight-hour shift.

INTRODUCTION OF LOADING MACHINE INEVITABLE

It is evident from the tables and data presented that the loading machine has established such a degree of efficient operation and such a magnitude of tonnage production as to assure its inevitable ultimate adoption in the coal industry. When contributory changes have been made such as will afford rapid transportation of coal to the tippie, speedy handling of cutting and drilling, efficiency in company work and maintenance and such a modification of the system of development as will favor the mechanical loader, the loading machine will introduce a new epoch in the history of coal production.

Haulage for Machine Loader.—In machine loading the haulage problem, as indicated by the percentages of lost time, is even more important than in hand loading. The movement of the coal while the loader is in operation is practically continuous. The movement of the coal in the mine cars is sadly interrupted.

In one of the mines where observations were taken, for example, two locomotives alternately took groups of cars into a room to the loader, replacing the cars as fast as they were filled, remaining with the loading machine until the trip was loaded. The cars were hauled to the main parting in short trips, and in order to avoid the still more expensive idleness of the loader, two other locomotives were employed for this work, these two locomotives spending more than half their total time in waiting.

For example, the average time for the round trip to the parting required 23 minutes, of which 10 minutes was actual running time and 13 minutes waiting. The need here for definite control of transportation, to which reference will be made hereafter, is evident.

Machine Cutting and Drilling in Conjunction with Mechanical Loading.—With the development of machine loading, a prime essential is to plan the management of all the operations, including the cutting and drilling, so as to keep pace with the loading. With this in view the arcell machine, which remains permanently on its truck and which is said to require less labor to operate per ton of cutting than any other cutting machine, has been used. It swings around a semicircle 18 to 21 ft. in diameter, cutting a semicircular kerf in the coal seam. This gives a convenient shape of face for loading. With this plan it has been found possible with one machine and two operators to cut 350 to 400 tons per day.

With machine loading the drilling must be done by a separate gang of men. For this an electric drill was found to be cheaper and quicker than the ordinary hand auger and to be an essential adjunct in preparing coal for the loading machine. A comparison of studies made to ascertain the net times of drilling in various mines indicates that in similar coal the net drilling speed is some five times greater when the electric drill is used instead of the hand auger.

This division of labor also is economical in specializing the work and inducing greater skill, and, therefore, more efficient work. Furthermore, the work can more readily be placed on an incentive basis.

Comparison of Hand- and Machine-Loading Mine.—In order to obtain a true comparison of production and cost of hand vs. machine loading it is necessary to compare conditions where the machine loader is the only variable. Fortunately, for this purpose we were able with the co-operation of the operators and men in the mine to make arrangements for studying machine loading in a mine recently changed over from all hand loading to all machine loading. The physical conditions in the two cases, therefore, were alike and the differences in number of men and in production per man were due simply to the change from hand to machine loading.

The table of comparison of hand and machine loading which follows gives the distribution of the men underground and complete information with reference to the coal loaded and the output per day. Five columns are given in the table. The first column gives the results from a single complete day's observation of the machine; the second column similar data from the records of the company for a six days' performance with three loading machines (this was during a period of two weeks in June, 1923, the mine working intermittently) while columns 3 and 4 give similar information of another mine, column 3 for one day's observation on a single machine and column 4, six days' actual running of the mine with two loading machines.

NUMBER OF MEN IN MINE ALMOST HALVED

Records from the same mine outlined in columns 3 and 4 are shown in column 5 with all hand loaders during the period of two weeks or eight working days in October, 1922. On account of the like conditions a comparison of hand vs. machine loading can be clearly drawn by comparing the various values in columns 4 and 5. It is interesting also to check these machine data with the other mine shown in columns 1 and 2.

It will be seen that the total number of men in the mine in column 5 is cut nearly in two for equivalent production; that is, 118 men underground for 733 tons per day against 73 men underground for a production of 814 tons, the average daily tons per man under-

FIG. 2—OPERATION CHART, LARGE AND SMALL LOADER

Horizontal lines in the graph show the time when the machine is being moved from one working place to another, not the time waiting for cars, which latter has been merged into the total time of loading at any given working place. Sloping line shows gross rate of loading, including waiting for cars.

ground, all men counted, being increased with the machine loader from 6.2 tons to 11.2 tons. Note further that the hand loading in this mine in the previous period was much above the average, or 13.8 tons per hand loader per day.

The average output per loader per day in Table III is slightly higher than the average of the tabulation in the previous table, because the men, who were only getting about three days' work a week on account of railroad car shortage, were working a little over eight hours per day.

The use of machines in mines with thick partings which cannot be picked out of the coal fast enough to avoid delaying the machine loader, may necessitate changes in the methods of cleaning. It may be necessary to supersede entirely hand sorting at the face by installing more and better cleaning devices at the tippie. The cost of such extra cleaning, even if appreciably large, will be overbalanced in most mines by the saving in the cost of loading.

A handicap in some sections, which, however, cannot be permanent, is the tendency of the union, on the introduction of any labor-saving device, to seize nearly the whole of the advantage by demanding piece rates high enough to make the cost of the coal practically the same as before. It is inevitable that eventually all savings of this kind, except that portion needed to pay a fair return on the development, must inure chiefly to the consumer.

Advantages of Machine Loading.—The saving in cost of mining by the coal loader is only one of its merits. Its value to the miner himself is of great moment because it eliminates the hardest and most lonesome work in the mine—shoveling coal—and also, because—this is of even greater importance—it increases safety by concentrating and speeding up the work. The latter advantage becomes important as the capacity of the loading machine increases.

Picture the difference in the operation of a hand and a machine loading mine. In the hand-loading mine in 7-ft. coal we get an output of 400 tons from a given section. We have some 30 to 50 hand loaders working in as many rooms in a territory of, say, 25 acres. These men advance in their rooms perhaps for four months until the maximum length of about 300 ft. is reached.

With machine loading, using a large loader in 7-ft. coal, even with the room-and-pillar method of development, which probably can be improved, the area operating at one time for a section of a mine yielding a 400-ton output can be reduced to some three acres, or less than one-eighth of the area of the hand-loading mine producing the same output. With a small loading machine the ratio is much greater. The necessary acreage in all cases varies with the thickness of the coal.

What does this mean to the miner and the operator? It means that the foreman, instead of making an occasional visit to the miner—say once or twice a day—is in constant touch with all the men. He can inspect the timbering. He can insist on the most economical methods of shooting. He can regulate and follow up the company daymen. He can supervise the track and maintenance work, and especially he can be in such close touch with all the men that accidents must inevitably be reduced to a minimum, yet at the same time all the work progresses more rapidly and at less cost. Further than this, because the room is excavated in, say, one month or maybe a half, instead of four months, and pillars can be recovered with similar rapidity, the danger of falls is lessened to a remarkable degree and timbering may be reduced in quantity and less coal be wasted.

Of paramount importance from the standpoint of observation is this larger recovery. It is estimated by operators using the large loading machines that the introduction of these labor-saving devices has increased the recovery by as much as 5 to 10 per cent.

Development Plans With Machine Loader.—Though our observations show conclusively that room-and-pillar methods can be used with machine loading, it is evident from the facts just given that some other system which will reduce the time lost in changing cars and moving the loader will be of further and correspondingly larger benefit. In mines already in operation, the plan of development is difficult to change, but for new workings, operators most interested in mechanical loading have considered modifications of the longwall system.

In one of the modified longwall systems the use of belt conveyors has been considered, in another a steel portable conveyor has been successfully used, and even with the room-and-pillar method there is a possibility of developments of this kind.

Work of Company Men with Machine Loader.—With the use of a machine loader many duties which now fall to the hand loader pass over to company men. Such work as timbering, laying track in rooms, cleaning up after the loader and removing rock or slate are necessarily done entirely by men who can be specially trained for this work. Furthermore, these men work in a small area and under constant supervision of foremen, which is impracticable where individuals are scattered in work places widely apart. Consequently they can be more effectively employed and at correspondingly lower unit costs.

The last three columns of Table III, which give the actual number of inside men employed in a mine operating entirely with machine loaders and the same mine before any loaders were introduced, show the distribution of the gang—except the loaders and men on machine shooting—to be substantially alike in the two cases, notwithstanding that all the timbering and trackwork in the machine mine is being done by company men. Longer operations (the loading machines have

been working only about six months in this mine) and further standardization, which is possible with men under such definite control, is bound to effect still greater reduction in the working force.

TABLE III—COMPARISON OF HAND AND MACHINE LOADING

MACHINE-LOADER MINE 40 PER CENT MORE EFFICIENT

Mining Costs Reduced with Large Machines.—At the beginning of the report the statement is made that in many cases the total cost of coal at the mine, that is, f.o.b. railroad cars, may be reduced as much as 30 per cent. This statement is based on careful estimates covering various physical and operating conditions. The reduction in the number of men underground has already been noted, and, as there indicated, with a longer period of operation this number will be reduced still further because of more systematic supervision and distribution.

Including the outside men so as to include all mining labor (exclusive of camp operation and maintenance) the output per man shift for all the men employed at and in the mine becomes 4.7 tons for the hand-loading mine to 7.7 tons per man for the large machine-loading mine. This is a reduction in total mining labor underground and outside of nearly 40 per cent. Taking into account differences in rates of pay, interest, depreciation and repairs to loading machine, different quantities of supplies, overhead in both cases and indirect labor maintaining mining town, the reduction in cost per ton in the mine under observation is somewhat larger than the 30 per cent presented as our estimate.

Increased Output from the Mine.—The introduction of loading machinery, instead of making so large a reduction in the number of miners, may be utilized in increasing output. Certain operators have estimated from their cost records that by running a mine full time, instead of on half production due to lack of railroad cars, that their reduced overhead and non-productive labor per ton (which items as a total are nearly independent of production) lowered their costs nearly 50c. per ton. Similarly, increase in production with the same overhead and equipment will produce large savings.

In some cases the ultimate increase in production is limited by the capacity of the shaft or tippie, but our observations show that by more uniform operation, by

utilizing the time lost through the day, and by the adoption of the best methods of operation, there usually is a remarkable opportunity to increase production without increasing either the inside or outside equipment. Furthermore, through the reduction in cost due to increased output combined with other savings directly due to loading machines and their accessories, the mine is placed in the class of low-cost production with naturally more uniform operation throughout the year because of readier sales.

Limitation of Loading Machines.—The loading machines thus far developed are limited to coal beds having a thickness of about 48 in. or over. This, however, includes most of the coal mines now being operated. For thinner beds satisfactory machines undoubtedly can be designed when needed although naturally the thinner-bed mines will fall in the class of higher cost, which, unless the coal is of exceptional quality, would operate only on a market with large demand.

Though best adapted to a sound roof, loading machines are being satisfactorily used even where the roof is weak. As a matter of fact—and this is of great importance—the speed of loading of the larger machines is so great that danger of falls is appreciably reduced.

It is not the purpose of this report, however, to consider such details, no matter how important, except to indicate the probable trend of progress in management. We may say, however, that one of the chief dangers of longwall mining with thick seams, that of falls which injure miners or tie up traffic, is minimized with large machine loaders because the speed of excavating makes it more possible to get out of the way before the roof falls.

LOADER HAS TRAILED BEHIND OTHER MACHINES

Present Accomplishments in Mining Machinery and Equipment.—Let us see what has been accomplished in underground machinery up to the present time. Electric locomotives with overhead trolleys are universally used for the haulage of trips on main lines and cross entries. The bottoms and partings and first-aid and office rooms underground, and sometimes (although in fewer cases than might be desired) the workings themselves are lighted by electric lamps. Storage-battery and reel locomotives and electric room hoists are widely superseding the mule for gathering from the working places.

Undercutting of the coal by hand has been largely eliminated by the cutting machine. Drilling is still usually done by hand augers, but in machine-equipped mines the electric drill is coming into use. Ventilation has become a science giving sufficient fresh air in every room and passageway. Drainage is handled by pumps of plunger, piston and centrifugal type—tandem for higher lifts—of the latest design. Outside machinery at tipples and power plants is sometimes highly developed. Watering with a specially designed sprinkler is employed underground in the best equipped mines.

The big possibilities of machinery in coal mining now are in the underground loading and in the adaptation of other underground operations to this method of operation. Experiments have been made with loading machines of various types for some ten or fifteen years. In metal mines their use is quite extensive, but in coal mines they are only just now arriving at a stage where they can be called an operating success.

Machines combining cutting and loading have not yet

been proved successful. "A cutting and loading machine however, has just been completed which is designed particularly for longwall operation. The machine advances steadily but slowly into the face of the coal, undercutting it, and the coal so undercut—by the arrangement of the mining method—falls with little or no drilling and blasting on to a conveyor with which the machine is equipped. This conveyor carries the coal to a haulage road where it is loaded into mine cars and so conveyed to the tipple."

A handicap in the development of loading machines has been not merely the overcoming of mechanical and physical difficulties but also the opposition of the Union,

FIG. 3—OPERATION CHART IN SINGLE PLACE
Horizontal lines in this graph show times when loader waits for cars and sloping lines show the net rates of loading.

which has opposed their introduction, or has attempted to attain so high a rate of pay for operating the machine as to deprive them of a large part of their economic value.

Many types of loading machines have been tried. In the West with the softer coal and thick seams electric power shovels of the steam-shovel type have been adopted although regarding these we have no records showing any such large output as we have observed with the type having two conveyors. A modification of this type that is being developed for coal mining in thinner seams is a bucket that is forced into the pile of coal and then lifted backwards and discharged onto a conveyor.

In connection with the loading machines and also in hand loading, experiments are being made at the present time with mine conveyors of various types. For outside operation belt conveyors, often in more than one section, are frequently used for distances of several thousand feet for delivering material for shipment, as for instance, to barges. In one mine visited a belt 400 ft. long carried coal on an incline from the mine to the tipple.

In anthracite mining, belt conveyors have been used at the working place, arranged so that a gang of shovelers distributed along the face shovel onto the belt. For bituminous mines extensive conveyor installations have been proposed and designed. In metal mining, conveyors 6,000 ft. long have been used. Eventually development in loading and transportation may result not only in revolutionary changes from the present "room-and-pillar" method but in the elimination of

the hauling of coal by cars and locomotives and its replacement by some other form of transport with changes also in the methods of cleaning and preparing coal for market.

Summary of Gains from Machine Loading.—Loading is performed at a fraction of the time and cost of hand loading; undercutting can be performed more systematically and efficiently; drilling is done by electric drills; hauling is simplified and trips can be scheduled more definitely and haulage costs reduced; less timber is used; roof falls less readily because of speed of progress and, in longwall work, less working room is required; concentration of workings produces large tonnage in small areas, inspection and supervision being more effective because of the smaller area kept active; cost of track equipment and maintenance is reduced by having fewer rooms or if longwall is provided by having no rooms whatever; cost of drainage is reduced by the smaller active area; cost of ventilation is lowered for similar reasons; cost of plant construction per ton and maintenance is reduced by reason of the larger production per man; waste of coal is lessened by larger recovery; safety—the most important factor in mining—is increased. This is due to concentration of area worked, and closer supervision.

Use Elevating Graders and a Steam Shovel In Large North Dakota Strip Pits*

RARELY does one find elevating graders in use for the removal of overburden in strip pits, but in the valley of the Missouri River, near Garrison, McLean County, at a point almost in the center of the State of North Dakota, Stevens Bros., contractors, of St. Paul, Minn., are using six machines of this type to uncover the lignite over an area of 140 acres.

The deposit is situated one and a half miles south of Garrison, a town of somewhat over 700 inhabitants, on the Soo Line. The property is exceptionally well situated for the method of operation adopted. The coal bed, which is 7 ft. thick, is covered with overburden to a depth of 20 to 30 ft. This consists of 6 to 8 ft. of surface gravel, followed by 3 to 5 ft. of yellow clay, below which is a 1 ft. bed of slack lignite, 3 to 4 ft. of yellow shale, 2 ft. of hard coal and 6 to 10 ft. of blue shale.

The property is cut through by the Garrison Creek

*Abstract from an article in *The Excavating Engineer*.

ROAD GRADER ADAPTED TO COAL STRIPPING

Two elevating graders which dig and convey surface material to wagons driven alongside make a speedy way of loading up overburden, it being sufficiently soft for such a manner of operation.

Valley, which offers a convenient pit for depositing the overburden. The coal to be mined is an excellent, exceptionally hard, smooth and lustrous lignite, similar to cannel coal in texture and appearance. The method of stripping the three pits is, in general, similar. In No. 1 mine the first "swipe" was taken with a tower drag scraper, and the rest of the cover by the methods followed in No. 2 and No. 3 mines. This is about to be described in reference to the last-mentioned of the three pits.

In that mine six elevating graders are used to do the main part of the stripping over the entire surface of the pit, removing, in the course of one series of operations, 1 ft. of overburden. The graders are hauled by six 10-ton tractors and deliver the material which they plow and elevate to from sixty to one-hundred dump wagons, ten or more wagons being allotted to a single grader. The haul averages about 1,000 ft.

The shovel has a 1-yd. dipper and is mounted on caterpillars. It is used for taking the heavy cuts and for removing the sloping banks which are necessarily left by the grader operations. It delivers on an average about 800 cu.yd. per day, loading the material into dump wagons. It also is used for mining the uncovered lignite, although about 50 per cent of this, up to the present, has been mined by hand. Some of the strip material is being dumped back into other parts of the excavated pit.

STRIP PIT OF STEVENS BROS. AT GARRISON, N. D., OPERATED BY SIX ELEVATING LOADERS AND A SHOVEL.

The coal is taken to the tipple, a distance of about 1,000 ft. There it passes over shaker screens and is loaded into box cars by a box car loader. The capacity of the plant is between 500 and 600 cars per month, the coal being sold in North and South Dakota and Minnesota.

Engineers Society of Western Pennsylvania Discusses Thick Freeport Coal

AGAIN the oft discussed question of the identity and peculiarities of the Thick Freeport coal was the cause of disagreement at the bi-monthly meeting of the Mining Section of the Engineers Society of Western Pennsylvania, held in Pittsburgh, Pa., on Oct. 30, after a paper, "Thick Freeport Coal," had been read by John M. Rayburn, in which he characterized the coal as the "double thick Freeport coal." This terminology was attacked by Dr. Thiessen, of the U. S. Bureau of Mines, who first discounted the redundancy in the combining of the words "double" and "thick," and then declared that the coal dealt with in the paper is none other than the Upper Freeport measure.

Dr. Thiessen said his petrographic studies of thin sections of coals from various seams have proved that the composition and structure of coal from every seam changes gradually from bottom to top. Studies of the Thick Freeport seam, he said, bring to light the same gradation which convinces him that this much-debated measure is only an occurrence of the Upper Freeport bed which attained unusual thickness over limited areas in Allegheny County, Pennsylvania. According to Dr. Thiessen, one would expect to find a halt in the gradual change of composition and structure at the contact between the upper and lower branches of the Thick Freeport seam, if the Upper and Lower Freeport seams really came together. In his studies he has found no such break, nor can the fossils found in the Thick Freeport seam be associated with those of the Lower Freeport seam.

Many speculative thoughts were advanced as to the cause of sandstone wants which are so prevalent in areas where the Freeport coal is thick. Mr. Rayburn believes these were laid down following a quiet period because a shell of talc-like clay separates the rock from the coal. Cross-sections of the wants are unlike those of old stream beds and do not grade in the direction of drainage. Their shapes are irregular and their long axes

point in all directions proving that streams were not responsible for the wants.

The Thick Freeport seam has an average thickness of 86 in. and underlies an area of about 73,600 acres. It is estimated that the resources in this seam total 470,000,000 tons. Most of the coal is owned by industrial interests outside of Allegheny County. Coal men in the county failed to appreciate the value of this coal when the field was opened up, and stood aside while people from afar bought up tracts of this coal. It is now being used mainly for byproduct coking.

Prize for Best Battery Locomotive

LIEUTENANT-COLONEL G. R. Lane-Fox, M.P., Secretary for Mines of Great Britain, announces that, in order to encourage the production of a safe and efficient type of electrical storage-battery locomotive for use underground in coal mines and with a view to displacing pit ponies in deep and hot mines, Charles Markham, colliery director, of Ringwood Hall, Chesterfield, has placed at his disposal the sum of £1,000 to be offered as a prize for the best vehicle which fulfills certain specified conditions.

Much discussion has arisen in England relative to the treatment of horses and ponies underground, and the persons interested in legislating animals out of the mines are trying first to find substitutes adapted to British methods of haulage.

J. A. B. Horsley, Electrical Inspector of Mines; Sidney Bates, Institution of Mining Engineers; Roslyn Holiday, Mining Association of Great Britain; Roger Smith, Institution of Electrical Engineers, and Herbert Smith, president of the Miners' Federation of Great Britain, have consented to act as judges and with the co-operation of the Chief Inspector of Mines have drawn up the conditions of the competition.

This will be open to manufacturers of any nationality, Oct. 1, 1923, and will be closed on such date, not less than six calendar months thereafter, as the judges may determine. Working trials in England will subsequently be arranged of any vehicles which are selected for test.

Copies of the conditions of the competition can be obtained on application from A. M. Clegg, Secretary Electrical Storage-Battery Locomotive Competition, Mines Department, Dean Stanley Street, Millbank, Westminster, London, S. W. 1.

LOADERS ARE HAULED BY SIX 10-TON TRACTORS. LIGNITE IN BANK ON RIGHT IS NOT THE SEAM BEING MINED.

New Equipment

Viking Coal-Mine Gathering Pump

A NEW coal-mine pump for gathering purposes now on the market recommends itself by reason of its simplicity, as it has only two moving parts, a large annular gear or rotor and a small internal gear or idler. This pump, known as the Viking, is an application of a design hitherto applied successfully to pumping duties in several industries for handling liquids of high and low viscosity. As is evident from an inspection of Fig. 1, the rotor fits closely inside the casing, through which projects the shaft driven by means of a spur gear and bakelite pinion. The idler revolves upon a hardened

FIG. 1—MINE-PUMP PARTS

Simplicity of construction and ease of repair are very evident. The principle of operation depends upon the trapping of water between the external and internal gear teeth.

ground steel pin on the head of the pump by engaging with the rotor. Aided by the stationary crescent which is integral with the head of the pump, these two gears mesh at a point in the casing midway between the ports to form an absolute barrier. Water sucked in and trapped in the spaces between the teeth of both gears is forced out through the discharge port and there is no churning of the water inside the pump chamber. By reversing the direction of rotation of the gears the suction and discharge ports may be interchanged.

Because it has only two moving parts and is provided with a casing-liner which takes the wear instead of the casing, the efficiency of the pump can be easily

restored to a maximum by replacing one or more of these parts. Where the water is not acid, the casing and the casing-liner may be made of cast iron, but for general water conditions in coal mines bronze is used.

The characteristics of this pump are unlike those of a centrifugal pump; high efficiency is maintained under varying heads. In actual test conducted at the University of Iowa a 2-in. Viking pump at 440 r.p.m. discharged 101 gallons of water per minute against heads varying from 0 to 150 ft. at an average efficiency of 63 per cent.

The Viking pump will pump water and air, though the efficiency, of course, will be diminished depending upon the amount of air taken in with the water. For this reason it requires no attendance aside from that necessitated for starting or stopping, and for periodic replenishment of lubricating oil in the reservoir. Owing to the fact that the pump will pump water and air it needs no priming, which means that it will pick up again though it has lost its water.

The Viking pump is manufactured by the Viking Pump Co., of Cedar Falls, Iowa, which has placed the sole sale rights with Charles A. Saints, of the Power Equipment Co., Oliver Building, Pittsburgh, Pa.

Multiple-Contact Auxiliary Relays for A.-C. and D.-C. Service

AUXILIARY relays for use where it is desired to trip several circuit breakers from one protective relay are manufactured by the Westinghouse Electric & Manufacturing Co. The relays are made in two types, type M for intermittent duty on d.-c. circuits, and type MC for continuous duty on both a.-c. and d.-c.

TYPE M RELAY, COVER REMOVED. Automatic control of tripping circuits is protection of a high degree, as it reduces delays and maintenance costs.

circuits. These relays can be used, for instance, in the differential protection of a generator for tripping at one time the circuit breakers connecting the generator to two busbars and at the same time for opening the field switch. One of the contacts also can be used for energizing a bell alarm circuit. Each contact will make and break 10 amp.

The type M relay is provided with a direct-current electro-magnet suitable for various voltages and is furnished with either four or six contacts. Each contact is mounted on an individual phosphor bronze spring. The internal connections are so arranged that the current for the contacts comes in through one lead to a conducting bar on which all the contact springs are mounted. The four or six contacts are all insulated from each other.

The type MC relay is provided with an electro-magnet suitable for continuous duty on either a.-c. or d.-c. circuits of various voltages and can be furnished with either three or six insulated contacts. When energized the three-contact relay makes two independent circuits and breaks one, and the six-contact relay makes five circuits and breaks one. In the case of the six-contact relay, these circuits are not independent but have a common point. The construction of the contacts is similar to that of those on the type M relay, except that the breaking contacts are silver so as to insure a good contact without an excessive amount of initial tension in the helical spring holding the armature open.

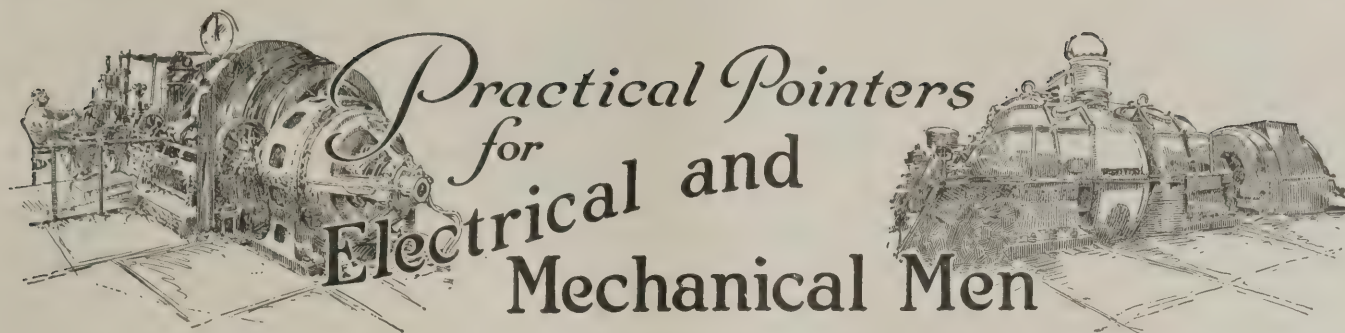

FIG. 2—MOTOR-DRIVEN UNIT

This arrangement gives a simple, compact pumping outfit suitable for easy transportation about the mines.

Repairing Ruptured Pipe by Oxyacetylene Welding

A RUPTURED or broken pipe is often the cause of a shutdown and concurrent serious production delays. Hence it is advisable to be prepared for such emergencies by understanding how to handle such a job and having the equipment necessary to its execution at hand when it does happen.

Forces, like so many other things, always follow the lines of least resistance, so that when a break occurs at a certain point in a pipe it usually is feasible to assume that the pipe was weakest at that particular point. In repairing the break by oxyacetylene welding it is well to keep in mind that the metal immediately in the vicinity of the break probably is weak also and for this reason it is best to remove it for a short distance back from the break.

If the break is a longitudinal rupture, as usually is the case, it may be repaired as follows: With an oxyacetylene cutting blowpipe cut away the ruptured and weakened metal, leaving a rectangular hole in the pipe as indicated by the dotted lines in the illustration. Then a rectangular patch of the same thickness and form may be obtained by cutting it from a stock or scrap length of the same size and class of pipe or it may be readily formed from a piece of sheet steel of the same thickness as the pipe wall. If this thickness is $\frac{1}{8}$ in. or more the edges of both the hole and the patch should be beveled to a 45-deg. angle with the cutting blowpipe, so that when the piece is inserted a 90-deg. V-shaped groove will be formed, thus permitting the welder to obtain full penetration of the joint when he butt welds the patch in place. A piece of rod welded to the patch will serve as a handle by which it

WELDING A PATCH ON A PIPE

The upper figure shows the section cut out and the lower figure shows how a patch has been put in position for welding. Chamfered edges permit the weld being made to the full thickness of the metal.

can be held in place during welding and can be readily cut off with the blowpipe after the welding is completed. This type of repair can be fully completed in an hour or two at very small expense and has the important advantage of being permanent.

Protecting Transformers and Motors from Damage Resulting from Single-Phasing

EVERYONE using three-phase alternating current has no doubt on some occasion experienced delays, burnouts and various other troubles due to equipment operating or tending to operate on single phase when something has gone wrong with the power supply, wiring of the control apparatus or the equipment itself.

Aside from being troublesome, single-phasing of a three-phase line may result in considerable damage to transformers and motors. Many types of phase-failure

FIG. 1—FUSING A TRANSFORMER BANK

Fuses in the transformer lead wires blow whenever the line wires single-phase.

devices have been placed on the market, but few if any appear to be entirely reliable and give 100 per cent protection. Perhaps these devices are not perfect in functioning because most of them depend for their operation upon voltage coils which under single-phase conditions have enough induced voltage applied upon them from the single operating phase to prevent them from properly functioning.

In the coal industry where many three-phase motors are used to drive fans and pumps, damage to these motors becomes a serious problem. If the fan shuts down for any considerable length of time, serious consequences may result, necessitating the men leaving the mine and the removal of mules. When important pumps shut down the whole pumping station and equipment may be drowned.

Single-phasing of lines feeding transformer banks also is a serious problem because many important motor drives may be connected to a single bank of transformers and single-phasing of the transformer bank immediately places a large amount of equipment in danger of being burned out.

A three-phase induction motor will not start on

FIG. 2—PROTECTING THE THREE-PHASE MOTOR
This connection gives the best protection against single-phasing.

single-phase but if once started on three phases it will continue to operate if single-phased. This single-phase operation is not always apparent to the operating man and as a consequence one phase winding of the motor carries the total load with greatly increased current and heating until finally it burns out.

For some time our company has been very successful in avoiding damage to equipment by fusing its transformers as shown in Fig. 1. It will be noticed that the fuses are placed in the transformer lead wires, the idea being that these fuses are of much less capacity than those required in fusing the live wires for a given load. The result is that when single-phasing occurs the fuses being placed in the transformer leads and being very nearly the proper current capacity of the transformers they quickly blow out when the additional load resulting from single-phasing comes upon any transformer.

FIG. 3—ANOTHER CONNECTION FOR THE THREE-PHASE INDUCTION MOTOR

The scheme of connection here is not so good as that shown in Fig. 2 because a ground in the motor frame may blow the fuse on one end of the phase winding and still leave the connection intact on the other. Thus the motor would have a circuit to ground and be dangerous.

Obviously the same method of protection may be applied to induction motors, but in order to do this it is necessary to bring out the end wires of each phase. If this is done it is possible to use several different methods of protection by the use of either fuses or relays. Fig. 2 shows how an induction motor might best be protected. Fig. 3 shows another connection for the protection of an induction motor. Fig. 4 shows how this protection may be applied to a motor starter.

Some manufacturers design their induction motors so that they may be connected to operate on two or more different voltages. Such motors may have the

FIG. 4—FUSING AND PROTECTING THE MOTOR AND STARTER

Note that this connection is similar to that in Fig. 2 and that it protects against single-phasing in the motor and starter.

proper phase wires brought out to a terminal board for the connections shown in the figures and thus lend themselves readily to the above method of protection; but there are many other motors on which this is not possible. Therefore it would seem that the manufacturer should be required to bring out the necessary phase wires so as to permit the adoption of the above scheme of protection.

Asks Suggestions for Recovering Timber In Anthracite Mines

WHILE making an inspection tour of one colliery of a large coal mining company in the anthracite region I was much impressed by the large amount of timber used, especially in robbing areas where the final recovery of coal is taking place. In many areas in this mine the roof is supported upon a forest of props and cogs which often constitute a menace to the further reclaiming of pillars left for roof support. When the roof is supported upon timbers, no cave takes place, but much of the resulting roof pressure is thrown upon the coal pillars, making the work of pillar mining difficult and oftentimes very dangerous.

I believe that by digging around the butts of the props, much timber could be profitably and safely recovered by means of a prop puller. There also are other cases where with a miner taking back top coal, the props could be economically and safely reclaimed. Let me illustrate. Some of our beds of coal lie on a pitch of about 25 deg. As the chamber advances we take the mining bench, which on an average runs about 7 ft. thick. Above this mining bench we have a parting rock, which is locally known as big slate. This slate oftentimes is found to be about 3 ft. thick, and usually is propped up as the chamber advances.

When the chamber has reached its limit we bring back the remainder of the vein as top coal, blasting down first of all the 3 ft. of big slate. This big slate and débris gather around the props, leaving only about 3 ft. of the upper end of the prop exposed. The top coal left is sound and solid and forms a splendid roof. To recover the props the miner would have to clean about 4 ft. of rock from about the foot of the props. It seems to me that under such conditions a prop puller would be ideal as a means of saving much valuable timber. This practice of reclaiming timber is extensively used in mining in Europe and in many well-managed mines in the bituminous regions of the United States. The Anthracite Mine Law, Rule 55, states, "No person or persons working in a coal mine or colliery shall cut out any props or timbers while the same are in position to support the roof or sides. When it becomes necessary to remove any of the said props or timbers for the purpose of mining coal that may be supported by the same, to dislodge any of the said props or timbers it must be done by blasting."

In view of the fact that the Governor of this state is so keen on forest conservation and timber preservation, would it not be well to have the mining laws amended so that they will meet the conditions of modern mining?

Perhaps many readers of *Coal Age* would be good enough to give us the benefit of their experience along the lines suggested above.

ANTHRACITE MINING ENGINEER.

Problems of Operating Men

Edited by
James T. Beard

Harmony and Co-operation Needed Among Mine Officials

Safety-First Type of Men Needed—Strict Discipline Required to Avoid Accidents—Miners Will Follow Foremen They Learn to Trust

SPEAKING of reducing the number of accidents in mines to which so many writers in *Coal Age* have referred and which is of the greatest interest to the coal industry, kindly permit me to offer a few suggestions that I believe are essential to the accomplishment of this purpose. No great aim or purpose can be attained, in any undertaking, without there is team work on the part of every one concerned.

Coal mining, above all other industries, needs men of the safety-first type placed in control of its operations. By this I mean, first, that the superintendent should be a man of good practical experience and judgment. In no way will his ability be manifested more strongly than in the selection of his assistant foremen. Without exception, they should be men who always put safety-first before everything else.

A superintendent should never be satisfied, unless the strictest discipline is maintained in every branch of the work and particularly underground. Prompt obedience to orders should be demanded of every one and violation of the rules should always be punished by a suitable penalty.

MANY SAFETY RULES SOON BECOME DEAD LETTERS

A penalty attached to a rule commands respect for its observance. Otherwise, many safety rules become dead letters to be followed or disregarded according to the whim of the worker. The result is a laxity of discipline that, sooner or later, will bring accidents.

Where it appears that the superintendent, mine foremen and assistants all work in harmony and have the same desire to make safety the first consideration, one is sure to find good results. The mine will have fewer accidents, because the same spirit pervades throughout the entire organization. Almost without exception coal miners will follow a good example set by a foreman whom they have learned to trust.

One of the most frequent causes of accidents in mines is the attempt to get cheap coal, which generally means a flagrant disregard of safety rules. Too often the mining laws are violated by both foremen and men, who take their own chances in not living up to the requirements of the law. In most cases, our mining laws are good and were enacted to safeguard both lives and property.

When a foreman neglects doing things that he knows require attention and puts aside such work for a few days, in order to keep down the showing on the cost-sheet, he takes chances knowingly and assumes a grave

risk. Should he succeed and no accident happen as a result, he will be more careless a second time. This will go on, until he finally meets disaster and an accident will occur that may cost many times the amount he managed to save by his departure from the rules.

It is at such times that a foreman will try to shift the responsibility for his own acts by attempting to fix the blame for the accident on one or more workers, who were simply carrying out his orders. It is my belief that if everybody, from the state mine inspector down to the trapperboy in the mine, would do his duty faithfully, and strive, in every possible way, to make the mine safe there would be fewer accidents and many lives would be saved.

MINER.

Duquoin, Ill.

Dewatering a Wet Hole in Blasting

Water accumulated in a hole drilled for blasting removed by simple device—Its use saves the miner both time and labor.

AMONG the many good things I have found in *Coal Age*, explaining ways and means of overcoming difficulties and saving time and labor, I have seen no mention of a simple device that came to my notice not long since.

In working for a large anthracite coal company and when visiting the various collieries on the property it has frequently been my good fortune to observe different methods of doing the same thing. Some ingenious mind often invents a contrivance that permits the mine worker to perform his duties in a more efficient and safe manner.

On one of my recent trips, I came upon a miner using an ingenious device of his own invention, designed for the purpose of dewatering a wet hole before charging the same for blasting the coal. It was in a place where the coal was being worked toward the outcrop and, naturally, there was much trouble caused by the seepage of water into the hole. Unless this water was removed immediately before charging, the shot would not do effective work and often a misfire would result.

SOAP AND OIL FAIL TO KEEP CARTRIDGE DRY

Different schemes had been used by the miners to overcome this difficulty. Some would soap their cartridges and others would oil them to prevent the water from coming in contact with the powder. These attempts would often prove fruitless and the cartridge would be drowned in the wet hole before it could be fired. It is unnecessary to say that such a condition entailed extra work and expense for the miner. Holes drilled to the dip, of course, proved the most troublesome.

In the instance I mention, the miner had taken a pipe of a somewhat smaller diameter than that of the hole drilled in the coal. In the end of this pipe, which

was a little longer than the hole, he had arranged a check valve, consisting of a disk of leather reinforced with an iron washer of a little less diameter. By drilling two small holes close to the end of the pipe and inserting a nail, he had succeeded in holding this valve in place so that the pipe formed a hand-pump.

HOLE QUICKLY CHARGED AND FIRED

Having drilled and cleaned the hole with his scraper, the miner would soap his cartridge and prepare his tamping in paper bags, or cartridges similar to that holding the powder. He did this to hasten the charging and tamping of the hole after pumping out the water. Then, by working the pipe with the valve in the bottom and plunging it quickly back and forth in the hole, he was able to extract practically all the water that had accumulated therein.

This being done, the charge was quickly inserted, the powder cartridge being followed by the tamping, which was rammed into the hole and the fuse ignited and the shot fired. There are doubtless different ways of fixing the check valve in the end of the pipe so that it will work effectively. One way would be to form a valve seat, by inserting an iron ring in the end of the pipe and placing the leather washer above it, confining its action by the nail inserted through the holes drilled in the pipe.

E. P. THOMAS.

Kingston, Pa.

Working Three Contiguous Seams of Coal

Large amount of waste material to be handled makes the economic working of the coal a difficult proposition—Room-and-pillar system of working preferred.

WITH much interest, I have followed the question of working three seams of coal separated by thick partings of slate and shale, as discussed by writers in recent issues of *Coal Age*. My interest was much increased by reason of the fact that the conditions described correspond very closely to what I encountered some years ago in my own experience.

In that case the rooms were driven up in the lower seam, the 4 ft. of top slate dropped and the 36 in. of coal above it allowed to fall. It was surprising to see the good results obtained. A large quantity of nice coal was mined in this way with scarcely any expense except for loading, which was easily done.

By arranging a chute of common boards placed at the top of the fallen slate and extending into the mine car, we were able to load practically all of the top coal with little effort. The coal was loosened with picks and handled mostly with our hands, scarcely ever requiring the use of a shovel.

In the question under discussion, it is desired to obtain the largest percentage of coal at a minimum cost per ton. Speaking generally, it is my belief that no longwall method of mining can be successfully applied to the working of these three seams as there is too much waste material to be handled. I doubt very much if the coal can be loaded into the mine cars, today, for less than \$10 per ton by employing the longwall method.

On the other hand, the three seams mentioned form a good proposition, if care is taken to adopt a suitable method of working out the coal. Like many other undertakings, however, the mistake can be easily made of choosing a wrong method, which will eventually cause much trouble and increase the cost of production. The result is a "gouging system" of mining.

It is my earnest hope that these remarks will not be taken as personally criticizing what has been said. My aim and desire is only that we may come to a better understanding of ways and means of mining coal, and be able to secure a little profit, while paying a living wage to the miner and marketing the coal at a fair price to the consumer.

In line with my own experience and assuming this to be a drift mine, I would suggest developing the property by driving the main headings two, three or four abreast, as desired, in the two lower seams. From these main headings I would drive double-entry butt headings to the right and left, on 400-ft. centers, turning rooms or chambers off these, on 24-ft. centers.

DETAILED PLAN OF WORKING

Judging from the description given, my plan would be to drive all entries and chambers 12 ft. wide, which would leave 12-ft.-pillars between the chambers. Probably the best plan of mining would be to shoot out the bottom coal a distance of 4 or 5 ft., first, and then shoot down the slate parting and the middle seam of coal. The coal should be loaded out first, after which the slate should be sent out of the mine to the slate dump.

If timbering is found necessary to support the upper parting, I would cut hitches in the coal seam and use short posts to carry the crossbars. It is my opinion, however, that little timbering will be necessary in this case, as the parting is a hard sandy shale varying from 4 to 6 ft. in thickness.

Now, drive four chambers to the limit and cut through the 12-ft. pillars, at that point, taking out the middle seam only and leaving the lower parting and the 12 in. of bottom coal in place. In the same manner, continue to draw back the pillars in these four chambers, say a distance of from 20 to 30 ft. Then, start a fall of the top parting, at the head of the chambers. It may be found necessary to load out a car or two of slate, in order to reach and mine the top seam.

My belief is that this top seam will fall easily and the miner will have the advantage of being able to load the coal of that seam directly into the car. The bottom coal and lower parting left in the pillars will now form a platform, or hogback, from which the top coal can be readily shoveled or handled into the car standing at the side of the pillar.

I would suggest using cars holding at least 3 tons. In case the top sandstone should break, it may be advisable to use plenty of timbers and leave a barrier pillar, between these four chambers and the next set, to control the break. The next four chambers are to be mined in the same manner as the first. In my opinion, this plan will afford a maximum extraction of coal, in these three seams, at a minimum cost of production.

Parnassus, Pa.

C. W. ATKINS.

Formula for Calculating Limit of Fall in Siphoning Practice

Calling attention to error apparent in development of formula giving limit of fall in a siphon line—Siphon could not operate—Discharge end higher than intake.

KINDLY permit me, as one of the interested readers of *Coal Age*, to draw attention to an evident error in the development of the formula for finding the limit of fall h_1 in a siphon line having a given rise or lift h , the lengths of the suction and discharge pipes being l and l_1 , respectively, and the diameter of pipe uniform.

The formula expressing the equal effective heads in the two branches of the pipe, as given in *Coal Age*, Oct. 4, p. 521, is correct.

$$\frac{34 - h}{l} = \frac{h_1 - 34}{l_1}$$

Transposed, however, this gives for the limit of fall,

$$h_1 = \frac{l_1(34 - h)}{l} + 34$$

From this last equation it appears the atmospheric head, 34 ft. at sea level, must be added to the other term, instead of being subtracted, as appears on page 521 of that issue. In the application of this formula to the concrete case given on page 522, we find for the limit of fall in a siphon having a lift $h = 24$ ft. and

the lengths of the two respective branches of the pipe being $l = 100$ ft. and $l_1 = 500$ ft.

$$h_1 = \frac{500}{100} (34 - 24) + 34 = 84 \text{ ft.}$$

The result found by making the last term minus instead of plus gave the limit of fall as only 16 ft., which would make the discharge at a higher elevation than the supply basin to be drained.

MANAGING DIRECTOR,

Coal Valley, Alta., Canada. Coal Valley Mining Co.

[We are glad to have attention called to this error in the development of the siphon formula on page 521 of the Oct. 4 issue. The limit of fall in the case assumed is 84 ft. as shown by correspondent.—EDITOR.]

Inquiries Of General Interest

Classification of Mine Having Two Openings

Increased Development Calls for Second Opening—New Shaft Operated as Separate Mine—Old Slope Reopened How Legally Classified?

AN ANSWER to the following questions through the columns of *Coal Age* will be greatly appreciated by a subscriber and constant reader:

A certain mine has been developed to a point where it became advisable to sink a shaft. At first, the purpose in view was merely to secure the better ventilation of the extended workings. Later, however, on going carefully over the situation it was decided to equip this opening as a hoisting shaft, as its location favored the shipment of coal on another railroad. The old fan proving inadequate for the ventilation of the entire workings, a new fan was installed at the shaft opening and the old fan shut down for the time. The slope was virtually abandoned, at least as far as hoisting operations were concerned, being used only to haul supplies and refuse in and out of the mine and as a manway for men going to and from their work. An additional shaft has since been sunk and provided with an extra hoist to handle slate and men.

REOPENING THE OLD SLOPE AS A NEW MINE

In the course of time, however, the old slope was again put into operation and coal is now hoisted and dumped over a tippie of its own, the coal being shipped on a different railroad from the one previously mentioned. The new shaft and the old slope are $3\frac{1}{2}$ miles apart. All entries leading from the slope to the shaft have been closed and sealed, except one that has been kept open for use as a manway and supply road. The old fan has again been put in operation to ventilate the workings on the slope side of the mine.

The question I want to ask is, Would this operation be legally classed as a single mine, the two openings being operated under the one management; or would the classification be two separate mines and require two foremen? As much interest has been attracted to

the matter in this district, I want to ask for a full explanation stating the reasons for the answer given.

_____, Pa.

INQUIRER.

In regard to the question of the two operations being considered as one or whether they would be classified as two separate mines, the fact that they are under the same management and control is of no particular consequence. As long as operations underground were confined to the new shaft, and the old slope was merely used for hauling supplies and refuse in and out of the mine, the entire development comprised but a single mine, ventilated by the new fan and hoisting coal at the new shaft. The situation would naturally call for but a single foreman, who would have charge of the entire mine.

On the other hand, when it was decided to reopen the old slope, start the old fan and begin hoisting operations at the slope, the management was virtually starting a second operation, which would naturally be classified as a separate mine. As is well known, the same company will frequently operate a number of mines, either adjoining each other, or in widely separate localities or districts. But each operation is then known and classified as a separate mine.

In the instance cited by the inquirer, the fact that the two openings are ventilated by separate fans, producing two independent circulations, and hoisting and loading coal at separate tipples, would seem to justify the employment of two mine foremen, each having jurisdiction over his own workings and held responsible for the output of coal, the safety of the men and the safe and healthful ventilation of the mine. The fact that there is maintained a manway or opening connecting the two workings would, in most cases, be considered as fulfilling the requirements of the law in regard to second openings, as furnishing a means of escape for the men in case of accident.

Capacity of Pipe to Hold Water

Approximate rule for estimating the capacity of pipes of different diameters—Exact method of calculation explained.

LOOKING through an old textbook a few days ago, I came upon a problem asking for the capacity of a 6-in. pipe, 12 ft. long, to hold water. The solution of the problem, as given in the textbook was based on the statement that a pipe 6 in. in diameter would hold a quart of water in each inch of its length. The rule seemed very simple and I was not long in estimating that for a length of 12 ft. (144 in.), the pipe would

hold 144 qt., or $144 \div 4 = 36$ gal. This seemed to me a very large quantity of water and I am wondering if the rule was correct. From one of the problems given in *Coal Age*, I attempted to figure the capacity of this pipe, but could not get the same result. As problems of this kind occur frequently in coal mining, I would much appreciate having the calculation explained.

Nokomis, Ill.

STUDENT.

The statement of the textbook, as quoted by this inquirer, should read a pint of water to each inch of length of a 6-in. pipe, which would be approximately correct and would make the capacity of a 12-ft. length of pipe, 6 in. in diameter, 144 pt., or $144 \div 8 = 18$ gal.

To find the exact number of gallons a pipe of any given diameter will hold, multiply the square of the diameter, expressed in inches, by 0.7854. Then multiply this product by the length of the pipe, in inches, and divide the result by 231, the cubic inches in a gallon.

Examination Questions Answered

Anthracite Foremen's Examination Districts 1 and 2, 1923

(Selected Questions)

QUESTION—What is meant by the terms "mixture" and "explosive mixture"? Explain fully.

ANSWER—A common mixture is one where two substances of different kinds are mingled intimately in any proportion. In other words, the mixture is simply mechanical, in distinction from a chemical mixture, in which the atoms of the two substances unite in definite proportions and heat is either evolved or absorbed, in the action that takes place. In a mechanical mixture there is no change of heat.

An explosive mixture is one capable of developing an explosion when heat is applied or other means used to produce that result. Methane and air mixed in certain proportions form an explosive mixture known as "fire-damp."

QUESTION—What great mine disaster was responsible for the Act of 1870, increasing safety and protecting the lives and health of those employed in mines?

ANSWER—The Avondale disaster of Sept. 6, 1869, resulting in the loss of 137 lives, so aroused public opinion regarding the need of adequate mining laws that the Legislature, the following year, enacted what was then known as the "Ventilation Act," which was the embodiment of the present mining law in Pennsylvania.

QUESTION—What three natural laws govern the flow of air in a mine?

ANSWER—The three laws that establish the relation between the pressure, velocity, quantity and power of a circulation, are the following: (1) Pressure, in mine ventilation, varies as the square of the velocity of the air current. (2) The power producing a circulation varies as the cube of the velocity of the air current. (3) For a constant power on the air, the quantity of air in circulation varies inversely as the pressure.

QUESTION—What effect has a regulator on the mine resistance?

ANSWER—The placing of a regulator in a mine airway has practically the same effect as lengthening the airway. The regulator forms an obstruction to the flow of air, which increases the resistance of that airway. The result is an increased mine resistance and a consequent decrease in the quantity of air circulated by the same power.

QUESTION—State the conditions in a mine where it is necessary to provide a separate travelingway.

ANSWER—The anthracite mine law (Art. 4, Sec. 4) requires a separate travelingway to be provided in a slope mine where the inclination is 15 deg. or less. Separate travelingways should also be provided whenever men are compelled to use a main haulage road when going to or from their work.

QUESTION—How are air measurements made and by whom? How are they to be recorded?

ANSWER—The anthracite law (Art. 10, Sec. 15) requires the inside foreman, or his assistant, to measure the air with an anemometer or other efficient instrument, at the inlet and outlet airways and at or near the face of each gangway and at the nearest cross-heading to the faces of the inside and the outside chambers or breasts where men are employed. These measurements must be made once every week and entered in the colliery report book.

QUESTION—How many cubic feet of air are passing in a gangway 10 ft. high on one side, 6 ft. high on the other side and 12 ft. wide at the bottom, the velocity being 300 ft. per min.?

ANSWER—Taking the average height of the airway as $\frac{1}{2}(10 + 6) = 8$ ft., the sectional area is $8 \times 12 = 96$ sq.ft. Then, assuming an average velocity of 300 ft. per min., the quantity of air in circulation is $300 \times 96 = 28,800$ cu.ft. per min.

QUESTION—What is meant by the term "diffusion of gases"? Explain fully.

ANSWER—The term relates to that property of air and gases having different densities and in contact with each other, by which their molecules intermingle. The molecules being in a constant state of vibration and the amplitude of vibration depending largely on the density of the gas, the result is a migration of the molecules causing the gases to intermix, which action is termed "diffusion."

QUESTION—How does the strength of props vary as to their lengths and diameters?

ANSWER—The strength of a mine prop, aside from the quality and kind of wood, depends on the ratio of the diameter to length of post being such that the timber will present equal resistance to crushing and bending. For average mine timber, this ratio is 1:12. In other words, the diameter of the post, in inches, should be equal to its length in feet. When the length of a post exceeds 12 times its diameter, the post will fail by bending if the load is excessive. Again, when the length is less than 12 times the diameter the post will crush before it will bend. For two posts of the same quality and kind of timber, their relative strength, in respect to bending, varies as the ratio of the fourth power of the diameters to the square of the lengths. Or, the relative strength, in respect to crushing varies as the square of the diameters. It is always a question of whether the post will fail by bending or by crushing, which depends on the length being greater or less than 12 times the diameter.

Coal Commission's Report On Anthracite Profits

Recommends Differential Taxation, Publicity of Accounts and Use of Hard-Coal Substitutes

Marked Variation in Costs Makes It Difficult to Supply Definite Information on Question of Profits—Average Would Be Misleading Because of Extreme Spread—Carrying Charges on Excess Coal-Land Reserves a Burden

Recommending that anthracite operators who have the good fortune to produce coal at a low price and realize a profit above the average should be subject to a special tax; that the federal government should be given power to require complete publicity of accounts, and that consumers of anthracite turn to substitutes for self-protection, the U. S. Coal Commission released on Nov. 10 its report on Investments and Profits in Anthracite Mining.

The Commission says that the man on the street wants a simple answer to the questions, "How much do anthracite operators make?" and adds that it would no doubt satisfy him to be told that the profit is so much per ton and yields the operator such and such a per cent return on his investment. "But such a simple answer cannot be truthfully given, however much it may be demanded by the consumer. It cannot be given because the business of mining anthracite is one of markedly varying cost and because therefore some operators pay very large dividends and others very small dividends, or sometimes no dividends at all."

Averages are misleading under such conditions and there is no single figure that represents either the profit per ton or the per cent return on the investment, and those who wish to find out the profits of anthracite mining must, according to the Commission, be prepared to consider extremes as well as the average and to weigh the evidence as derived from one method of valuation against the evidence from another, for the Commission has found no shorter way.

"Some light on profits is thrown by the margin per ton. The margin is the difference between the cost of production and the average sales realization f.o.b. mine on all coal sold. The margin is not the same as profit. From it must first be deducted federal taxes and interest on borrowed money before the amount available for the owners of the business is known. Even then it cannot be translated into terms of per cent return on the investment until the investment per ton is known, and as the investment of different operators varies, so the margin necessary to profitable operation varies from operator to operator.

"The margins of anthracite operators vary within the widest limits. In the year 1921 there were three operators who reported to the Commission a margin in excess of \$1.50 a ton. One of these three operators was a railroad coal company and two were small independent producers. To-

TABLE II—RANGE IN MARGIN PER TON, JANUARY TO MARCH, 1923

Total.....	66	18,049,000	100.0	

gether they mined 7.6 per cent of the total output. But in the same year there were eight other operators who reported to the Commission a loss of over \$1.50 per ton. These eight operators were all very small producers, and together they contributed but 1 per cent of the total output. They were independents who had high costs and who could not get satisfactory prices under the market conditions of that year.

"In between these extremes were ranged the remainder of the 74 companies reporting, as shown in Table I.

"It is pointed out that the size of margin necessary to profitable operation varies with the investment of the operator. One company may have heavy investments in machinery and equipment and thus show a relatively low labor cost, while another may have a small investment and a high labor cost. In the case of the first company the margin must be larger in order to give an equal rate of remuneration for the larger amount of invested capital per ton of product. Again, there are anthracite-mining properties affiliated with the railroads that are habitually run at a virtual loss in order to furnish traffic to the carrier and there are other companies subsidiary to a larger interest in which the cost of production is burdened with carrying charges on a large reserve of coal lands which is really held for the benefit of the parent company. But with due allowance for these other factors, it is still true that anthracite mining is characteristically a business of differential advantage and widely varying profits."

This fact has an important bearing on any proposal to reduce the cost to the consumer by reducing the profits of the operator. The margins of the high-profit companies, says the Commission, are clearly larger than is necessary to return an adequate income on the average investment, but the effect of any cut in the margin must be gaged not only with respect to the average operator or the high-profit operator but also with respect to the low-profit operator.

Lay Costly Mining Methods to Lack of Competition.—The Commission is aware that the costs of many operators are burdened with carrying charges on coal lands that will not be developed for generations and that the absence of competition in the anthracite region has encouraged the opening

of properties which could not be operated under more active competition, and has further made it to the interest of the producer to extract a larger percentage of the coal in the ground than was formerly the practice. It is conceivable, if not probable, that if faced by the absolute necessity of reducing costs, the industry would find means to mine coal more cheaply, but this result could not be accomplished quickly and would almost certainly entail waste of the resources.

This report of the Commission presents a summary of its investigations on margins as well as on profits, the signed report being accompanied by special staff reports on each of these subjects, both prepared under the general direction of David L. Wing. In its discussion of margins the Commission points out that the average margin is not in itself a safe measure of profit, although changes in margins show whether profits are increasing or decreasing.

"Compared to the margins before the war, present-day margins show a large increase. In the four years before the United States entered the war the average margin for the railroad coal companies was 37c. a ton. In 1919 the average margin (adjusted—see table III) was 61c. In 1920 and 1921 for these 10 companies it was 56c. and 85c., respectively, the variations in these years representing in part changes in price, in part the movement of steam sizes in and out of storage to the market. The average for 1921 was thus more than twice as great as the pre-war average.

"During the five-months' strike of 1922 the companies lost money heavily and operations for the year as a whole showed a loss. After the resumption of mining, however, margins rose to the highest point of record in the ten years. For the last quarter of 1922 the average of the railroad coal companies was \$1.15, and in the first quarter of 1923 it was \$1.18, or more than three times the pre-war average. The large margins of late 1922 and early 1923 were due in part to the active demand for steam sizes and in part to the fact that the railroad coal companies advanced the price of domestic coal slightly.

"The increase in margin over the pre-war years is in part attributable to federal income and excess-profit taxes, which are included in the margin and which before 1917 were negligible in amount. The average amount of federal taxes per ton of all coal produced by the railroad coal companies was found to be approximately 11c. Even after deducting federal taxes therefore the margin shows a large increase over pre-war years."

The evidence of the margin as to profits of anthracite operators is summed up by the Commission as follows:

"There is normally a wide variation in margins between the low-cost and the high-cost operators. Some operators make very large margins and others very small margins. Still others frequently have to sell below cost.

"Present margins are much larger than pre-war, even allowing for federal taxes. The margin in the six months

following the strike was the highest on record, partly because of market conditions which are not expected to be permanent, partly because of an advance in the circular price.

"Labor costs and other costs also show a large increase over pre-war figures, but the increase in price has been such that the operators' margin since the war has been about the same percentage of the sales realization as before."

Per Cent Return on Investment.—The Commission found itself confronted with conflicting claims as to the basis upon which the rate of income should be reckoned, and it outlines the theories, without, however, committing itself to any one. One claim is that the current market value is the proper measure of value. Another that the income should be reckoned upon original cost; another that it should be determined with reference to cost of reproduction.

The Commission "has deemed itself justified in finding" as a fact that the mining and transportation of coal in interstate commerce impresses that commodity with a public use. The problem of valuing anthracite therefore while not strictly analogous, bears some resemblance to the problem of valuing a public utility for the purpose of regulating rates. It will be found that the courts have laid down a single formula for ascertaining value. Each case seems to rest upon its own merits and the courts have considered original cost, stock and bond issues, and the cost of reproduction and have been governed in their decisions sometimes by one element and sometimes by another. As the Commission is not called upon to determine judicially the valuation of these properties, it does not deem it prudent to lay down a rule for making such valuation. The Commission has rather deemed it to be its duty to set forth for the use of Congress and the public all the information on these subjects which it has been able to obtain."

In order to arrive at an estimate of market values, the Commission secured without compensation the services of a committee of engineers who, it says, "through technical training and many years of experience as experts in the appraisal of coal-mining properties, were especially qualified.

"The method employed is that adopted by engineering experts in valuation of mining properties; that is, the basis being the present and the estimated future earnings. The objection to the valuation of properties in the anthracite field is that this basis is that of earnings derived from inherent monopolistic conditions, the uncertainty as to future mining costs and future realization margins—two factors highly speculative. Nevertheless, this method of valuation is that which is employed by the experts representing capitalists desirous of investing in anthracite mining properties, and is the accepted practice in such transactions involving value of particular tracts.

"The committee's estimate, including both physical property and working capital, also covers the value of lands not owned by operating companies. The committee's valuation is as follows:

Present valuation of lands now operated, including development, plant and equipment, and working capital.....	\$843,500,000
Present valuation of reserve tonnage.....	146,400,000
Total present valuation.....	\$989,900,000

"The Commission says 'that the current market value determined on this basis is not a satisfactory base against which to determine whether or not the anthracite companies have been using their monopoly powers to extract unreasonable profits,' and points out that 'if the estimate of the engineers correctly appraises the present market value of this industry it also measures the increment in value to the owners of the land.'"

Book values of the companies examined by the Commission's field accountants "after deducting outside investments, amount to \$520,000,000 with working capital included (counting the memorandum accounts of the Pennsylvania Coal Co., and Hillside Coal & Iron Co. as a part of the book value). The companies examined produced 85 per cent of the output and own in fee 81 per cent of the coal. If they represent a like percentage of the total investment in anthracite mining, the book value would be in the neigh-

borhood of \$600,000,000 or \$640,000,000 working capital included. In other words, the estimate of the committee indicates a market value some hundreds of millions in excess of the values now on the books of the companies, representing therefore a capitalization of monopoly profits."

The cost of reproduction is not a figure that can be obtained with respect to the anthracite industry because the largest values are in land and unmined reserves, "to which, of course, reproduction cost cannot apply." The values carried on the books of the anthracite companies, as found by the field accountants of the Commission, represent in most instances a figure below present market value, as estimated by the engineers, but above original cost. Like original costs and market values, the book figures are to be accepted as throwing light on the rate of profit although not conclusive evidence thereof.

What the books show is summarized in table V.

Commission Investigates Original Cost.—The report reviews at length the Commission's investigations into the original cost of the anthracite properties. It points out that all but two of the railroad coal companies other than the Pennsylvania and Hillside wrote up the values of their land for tax purposes some time between 1913 and 1921. The amount of these revaluations of property assets identified by the accountants in the books of each are shown on the last two lines of table V.

"The revaluations made between 1913 and 1921 by the railroad coal companies in the table totaled \$78,000,000, not including the \$40,000,000 in the memorandum account of the Pennsylvania and Hillside companies. In addition to the companies here shown, revaluations to the amount of \$15,500,000 were found on the books of the independent companies examined. To this should be added the appreciation of values which took place when the Delaware, Lackawanna & Western R.R. sold its property to the Glen Alden Coal Co. in 1921. Assets which at the time of sale showed a value of \$6,240,000 on the railroad company's books were entered on the Glen Alden Coal Co.'s books at \$72,240,000, an increase of \$66,000,000.

"The total increase in the book values of the companies examined arising from appreciation of values has thus amounted, since 1913, to approximately \$159,800,000 exclusive of \$40,000,000 in the memorandum account of the Pennsylvania and Hillside companies.

"The Commission was unable to obtain figures of the original investment; neither the records of the present operating companies nor the resources of the Commission were adequate for this purpose. As has been found by the Interstate Commerce Commission in the valuation of the railroads, accurate records of original cost in many instances do not exist. The most that the present Commission has been able to do is to set down the items of appreciated value which could be identified on the books, and it is probable that other appreciations of value not identified by the accountants have been placed on the books even during the life of the present operating companies.

"The total amount of appreciation of values identified both before and since 1913 was approximately \$186,000,000 exclusive of \$40,000,000 in the memorandum account of the Pennsylvania Coal Co. and the Hillside Coal & Iron Co.

"Those who hold to the theory of original investment as the basis for reckoning profit may, if so disposed, deduct these revaluation items from the book values in order to derive a figure closer to the original cost than the book values themselves. The Commission itself does not feel

justified in making the deduction, for several reasons. In the first place, it is not sure that all the appreciations in value were discovered. Again, the depletion allowances which have occasioned many of these write-ups have not yet been finally settled with the Treasury Department and are, therefore, subject to change.

"Again, the Commission cannot guarantee in all instances that the assets revalued are exclusively concerned with the production and sale of coal, though most of them relate to coal lands. Finally, some of these entries are explained by the companies as restoration to capital accounts of amounts previously charged off through excessive depletion and depreciation, or of improvements charged directly to operating expenses. In view of the accounting practice of some of the companies it is likely that the book values of plant and equipment are in some instances less than the original cost and subsequent improvements.

With these uncertainties still attaching to the entries it would be a departure from the Commission's procedure of strict conformity with the written records of the companies to make the deductions and to calculate the per cent of return on the resulting investment. The figures are, however, here presented for the use of those who desire to approximate original cost as closely as may be from the facts now at hand."

Increase in Net Income 1913-1922.—The figures of net income confirm the evidence of the margin per ton that the operators have been receiving larger returns since the war than before, says the report. In table VI is shown the combined net income from coal operations of all the railroad coal companies except the Glen Alden. From an average of \$13,000,000 in the three years 1913 to 1915 the income rose to \$33,000,000 in 1920. In other words it increased two and a half fold. In the following year, 1922 as a whole, the income was by far the smallest of the ten-year period but it is to be expected from the evidence of margin per ton that 1923 will show a relatively high income. Out of the increased income, it should be noted, federal taxes must be paid.

Table VII shows the dividends paid (exclusive of stock dividends) by the railroad coal companies for the years 1913 to date. The dividends are shown in two ways: first, in per cent of par value of capital stock; and second, in dollars and cents per ton of coal produced. The very high rates of dividends paid by certain of the companies should be considered in the light of their small capital stock, and in the first two lines of the table the figures of total assets and capital are given for each company for purposes of reference.

In table VIII are given the earned surpluses of the railroad coal companies as distinct from surplus arising through revaluation of assets. The first column of the table shows the surplus of the six railroad coal companies that have been paying dividends in recent years and that are engaged exclusively in the mining and selling of coal. The surplus

a Memorandum accounts for depletion and depreciation purposes indicate value of \$40,000,000 in addition to these amounts.

b Since the larger part of this company's net income is derived from transportation facilities, rate of dividend per ton is omitted.

c On account of operating agreements between Hudson Coal Co., Delaware & Hudson Co. Coal Department, and Northern Coal & Iron Co. rate of dividend per ton for the Hudson Coal Co. is omitted.

d Eighteen months.

of these six companies rose from \$9,700,000 in 1912 to \$53,000,000 in 1919. In other words it increased more than five-fold in seven years. In 1920 it decreased slightly, chiefly because of the payment by the Lehigh Valley out of its surplus of a dividend of 134 per cent. In 1921 the combined surplus fell to \$37,000,000, chiefly because of the payment out of surplus of another dividend of 227 per cent, this time by the Lehigh & Wilkes-Barre. Other large dividends were paid during the year, notably \$2,050,000 by the Hillside, equivalent to 205 per cent on its small capital stock, and \$6,850,000 by the Pennsylvania Coal Co., on its capital of \$5,000,000.

The Glen Alden Co., which took over the coal properties of the Delaware, Lackawanna & Western Railroad Co., in August, 1921, was omitted from the preceding tables by the Commission because the change of ownership makes it impossible to set up the accounts on a comparable basis. Were the company included the profits of the industry would appear larger. Its mine had the lowest average cost of any large operator in the region during the four-year period, 1919-1922. Its margins are, therefore, large and its earnings correspondingly so. For example, in the first quarter of 1923, the average margin of the other railroad coal companies was \$0.93 per ton. The margin of the Glen Alden was \$1.48. Including the Glen Alden the margin for all the railroad coal companies was \$1.04. In other words the average with the Glen Alden included was 11 per cent higher than with it excluded.

The Commission was unable to obtain a separation of the coal accounts and the railroad accounts of the Delaware, Lackawanna & Western Railroad Co. that would permit a statement of income from coal applied to investment from coal. It is a matter of common knowledge, however, that the business was highly profitable, and that the coal-mining department contributed largely to the prosperity of the combined enterprise. The dividends paid by the Delaware, Lackawanna & Western Railroad Co. have been as shown in Table IX.

Carrying Charges of Coal-Land Reserves.—"The greater part of the investment of the anthracite operators consists of coal-bearing land. Where, as is the case with a number

of companies, lands are held which cannot be developed at the present rate of output for some generations to come, the carrying charges become a serious burden. The taxes upon the undeveloped lands are charged to operating costs. The interest is not properly chargeable against cost, but it must come out of the margin. Carrying charges on excessive reserves are one reason why some of the substantial companies pay small dividends or no dividends at all.

"To ascertain the effect of such charges upon the profits of the companies examined, the Commission obtained the

b Including 35 per cent in securities of the Lackawanna Railroad Co. of New Jersey.

services of D. C. Ashmead, formerly of the Commission's engineering staff and later of the Bureau of Mines, to estimate the probable life in years at the present rate of output of each of the companies whose accounts were examined. From the information furnished by the companies to the Commission Mr. Ashmead has estimated the total tonnage of recoverable coal in the lands controlled by each company, and has divided this by the company's present rate of annual output.

"The Commission does not itemize the individual estimates. In order, however, to show the wide range in the amount of reserves carried by the several companies, table X has been prepared, in which each operating interest is shown by a code number only. The table gives for each interest the life of the property in years at the present rate of output, including all coal, whether owned or leased, now controlled by the interest. The table also gives the per cent of the tonnage controlled by the corporation that is in fee and the per cent in leasehold. To illustrate, company No. 3, has coal enough in the ground to keep on operating for 123 years at the present rate of output, and all of this coal is owned by the operating company. Companies No. 7 and 8 have coal enough for 98 years of operation of which 59.5 per cent is owned in fee and 40.5 per cent is controlled under lease.

"The outstanding example of excess reserves of coal-bearing lands is the Philadelphia & Reading Coal & Iron Co., which owns 85,000 acres of coal lands. According to a semi-official estimate made some years ago the coal in these lands is sufficient to last for 216 years. The engineering department of the Coal Commission estimates the life of the property at a still higher figure. The taxes on the excess land add to the already high production cost of the Reading and reduce its margin. Freed from this extra tax burden the margin might be sufficient to pay a modest return if applied to a simple investment in operating properties. Spread

Mined out			

over this vast future reserve, the actual margin has paid a very small return.

"At first sight it would appear that the Philadelphia & Reading Coal & Iron Co. has been extremely unprofitable. Its production cost has indeed been high. The peculiar difficulty of the Reading has apparently been to pay the taxes and interest on its enormous reserve of coal lands. Had the anthracite business been an ordinary competitive business and the Philadelphia & Reading Coal & Iron Co. an ordinary competing business enterprise one of two things would have happened long ago. The company would either have been forced out of business or else forced to sell part of its coal lands to someone else. The thing that saved the Reading Coal & Iron Co. was the absence of effective competition, due to the peculiar economic organization of the anthracite industry.

"The Supreme Court of the United States has declared this combination of the [Reading] railroad and coal companies to be in violation of law and has ordered a dissolution. This is in line with good public policy. The business of mining and transportation should be kept separate, not intermingled, as now, in a maze of accounts.

"The Commission insists that the dissolution ought not to be made the occasion for further increases in the price of coal. The coal company has been operating under an arrangement by which the railroad paid the carrying charges on the excess coal lands. If this arrangement is illegal, the excess reserve should be taken care of by some other means than through an advance in the price. The American people do not want their coal at prices that will not yield a fair profit, but they do not believe that it is an inherent right of any corporation to embark on a two-hundred-year speculation in land and ask the public to pay the cost of carrying it out of the present price of coal.

"Summary and Conclusion.—The principal facts found by the Commission in its investigation of anthracite profits are:

"(1) No average figure either of margin per ton or per cent return on investment can fairly represent the profit in anthracite mining. Because of great inequalities in cost and in selling arrangements some operators make very large profits and others very small profits. The margins per ton between cost and sales realization in ordinary times range from less than nothing to over \$2 a ton. The per cent return on book value of investment in coal ranges all the way from a loss to 138 per cent (one independent operator, year 1917).

"(2) There has been a very large increment in value so that the lands are now worth on the market more than they used to be although a third of the coal is gone. The Commission could not obtain the original cost of more than

one or two of the properties. It did find that the present book values contain certain "Write-ups" or revaluations of assets amounting to at least \$186,000,000 and in addition there were memorandum accounts kept for Federal Tax purposes indicating further appreciation of \$40,000,000.

"(3) The latest of the foregoing revaluations, however, was as of 1913. Since 1913 a further huge increment in market value has accrued to the owners of the property. A committee of engineers appointed by us estimates the present market value of mines and minerals as \$989,000,000. The book values, allowing for companies and holdings not examined by the accountants, are in the neighborhood of \$600,000,000. This indicates a further increment of hundreds of millions of dollars inuring to the owners if the engineers' estimates based on earnings are accepted.

"(4) The profits are increasing. Total net income is increasing, dividends are increasing, and surpluses are increasing, earned surpluses as well as surplus arising through revaluations. The margin per ton is increasing.

"During the year 1922, when there was a five-months strike, the average total f.o.b. mine cost for the year as a whole exceeded the sales realization of the operators. Their margins per ton for the last quarter of 1922 and the first quarter of 1923 were the largest on record. Though the market conditions of 1923 are not expected to last, it is found that the present margins show a large increase over pre-war, even after deducting federal taxes.

"(5) Labor cost and other costs also show a large increase over pre-war figures, but the increase in price has been such that the operator's margin since the war has on the whole been about the same percentage of the sales realization that it used to be.

"(6) The practice of many companies of carrying large reserves of coal lands held for future use adds to costs through taxation and conceals profits. The largest of the railroad coal companies—the Philadelphia & Reading, a high operating cost company—is overburdened with reserves sufficient to last more than two hundred years. On this total investment it has shown an inadequate return, the loss having been made up by the large earnings of the affiliated railroad. Freed from the carrying charge of this excess reserve it could make an adequate return.

"The amount of the increment in value of coal lands is a matter deserving careful consideration, not only with respect to anthracite but also with respect to bituminous coal. If this increase in market value is to continue indefinitely piling up carrying charges to be added to current prices, an intolerable burden will be laid on the consumer. Taxes and interest on coal not to be mined within forty years are not properly chargeable to present operations. Speculation in land should not be confused with mining coal.

"We make the following specific recommendations for the attention of the industry, the states and the Federal Government:

"(1) In order to permit the public as a whole to share in the good fortune of the low-cost, high-profit operator, we recommend that differential taxation shall be applied to differential advantage. Sweeping horizontal cuts cannot be made in present mine prices and margins without serious injury to many high-cost operators, whose output is needed. Taxes falling lightly on the low-profit operator and more heavily on the high-profit operator in proportion to his ability to pay will benefit the consumer indirectly through lightening the tax burden elsewhere and will accomplish this without raising prices.

"(2) To protect the public against unjustified increases in price, we recommend complete publicity of accounts through a federal agency with power to compel reports, and to prescribe the form of accounts. Because of the large increase in operators' margins per ton since the strike of 1922, and the possibility of further increases in price as a result of the recent settlement, we believe that such current publicity as to costs, margins and profits should begin at once. Unless the public is protected by publicity of accounts, we are apprehensive that the concentrated control of the industry may take indefensible profits.

"(3) The consumer has in his own hands a measure of protection against unreasonable profits. We commend to consumers the use of substitute fuels."

Explosion in Glen Rogers Mine Kills 27

A gas explosion in one entry of the Raleigh Wyoming Coal Co. mine at Glen Rogers, W. Va., just as the men were starting work Nov. 6, caused the death of twenty-seven miners. Sixty-three men had checked in at the mine mouth that morning, and it is believed that the thirty-six survivors owe their escape to the modern ventilating system with which the mine was equipped.

Carl Scholz, vice-president and general manager of the Raleigh Wyoming Company, and R. M. Lambie, chief of the state mining department, could assign no cause for the explosion. In some manner unexplained, gas had accumulated in the entry where the blast occurred, but how it came to be ignited is not known at the present time.

The mines were not working the night before the explosion although until recently double shifts had been operating regularly. Through the night 28,000 cu.ft. of air had been passing through that heading, and the large ventilating fan had never stopped for a minute. Two night firebosses had made an inspection of the mine at 7 o'clock on the morning preceding the explosion and reported it safe.

QUESTIONS INVOLVED in the case of the Diamond Coal & Coke Co., versus the Oregon Short Line R.R. will be argued before Division 4 of the Interstate Commerce Commission in Washington Dec. 21. The case of the Southwestern Interstate Coal Operators' Association versus the Arkansas Western Ry. will be argued in Washington Dec. 28. The traffic questions raised by the South Side Lumber & Coal Co., the Peoples Coal & Material Co., and the Citizens Coal & Supply Co. will be considered at an Interstate Commerce Commission hearing in Indianapolis Dec. 4. Examiner Carter will preside.

BANKERS' ACCEPTANCES, secured by warehouse receipt, are eligible for rediscount by Federal Reserve banks when used to finance the storage of coal on docks, provided they comply as to maturity and in all other respects with all

other provisions of the Federal Reserve Act and the board's regulations, says a ruling of the Federal Reserve Board. The ruling, which was made in response to a request as to the validity of such financing, also provides that the acceptances, secured by warehouse receipts, are eligible for acceptance by member banks.

September Mine Fatalities at Low Level

Fatal accidents at coal mines in the United States during September, 1923, numbered 137, according to a report by the U. S. Bureau of Mines. The fatality rate was 2.79 per million tons, based upon 49,133,000 tons of coal produced during the month, as compared with a rate of 5.11 for the preceding month based on a production of 57,732,000 tons and of 3.87 for September last year based on an output of 44,488,000 tons. The fatality rate for bituminous mines alone was 2.62 as compared with 3.76 for the same month last year; the rate for anthracite mines was 5.49 as compared with 4.73. The average fatality rate for September for both classes of mines during the past ten years was 3.66 per million tons. Thus the rate for September, 1923, was not only lower than that for September last year but it was also much below the ten-year average rate for the same month.

The fatalities during September brought the total number of deaths in 1923 to 1,900, indicating a fatality rate of 3.92 per million tons, as against 1,234 fatalities during the same period last year, representing a rate of 4.11 deaths per million tons. The 1923 rate indicates a decrease of between 4 and 5 per cent.

The present year's record to date for all fatalities from all causes shows a reduction in the fatality rates per million tons for falls of roof and coal, haulage, explosives and electricity, and an increase in the rate for gas and dust explosions, as shown by the following figures:

	1922	1923
Falls of roof and coal.....	2.000	1.803
Haulage.....	0.760	0.670
Gas and dust explosions.....	0.393	0.642
Explosives.....	0.183	0.167
Electricity.....	0.183	0.134

Engineers' Valuation Committee

Appraises Anthracite Industry at \$989,900,000; That of Soft Coal at \$11,442,864,000

Norris Report to Be Submitted to Congress Though Not Accepted by Coal Commission—Valuation of Coal Industry Arrived at by Capitalizing Present and Expected Profits

IN ITS report on investments and profits in the anthracite industry the Coal Commission makes reference to a study of the valuation of the coal industry undertaken at its request by a voluntary committee of "especially qualified" engineers. This committee, of which R. V. Norris, of Wilkes-Barre, was chairman, the other members being S. A. Taylor and Howard N. Eavenson, of Pittsburgh; H. M. Chance, of Philadelphia, and J. H. Allport, of Barnesboro, Pa., made a report to the Coal Commission on the present value of both the anthracite and bituminous-coal industries. This report was not accepted by the Coal Commission, but will, it is understood, be transmitted to Congress with other supplemental data for printing in the completed report of the Commission.

Mr. Hammond authorized Mr. Norris, chairman of this Engineers' Advisory Valuation Committee, to make public the text of their report. This committee estimates the total present value of the anthracite industry, including reserves, at \$989,900,000, and of the bituminous-coal industry at \$11,442,864,000. The above figure for anthracite includes \$146,400,000 as the present value of the reserve tonnage, and \$5,156,650,000 for the reserve tonnage of bituminous coal and lignite.

The report points out that various methods of valuation have been suggested for mining properties, but that authorities seem to agree in accepting as the fairest, most practicable and logical a capitalization of the estimated future earnings if an estimate can reasonably be made. Hoover and Finlay are quoted as authorities on this point.

Cost, assessed valuations, sale value, royalty valuation and tonnage values were considered by the committee as possible means of arriving at a general value of the coal industry. The method adopted, and "used as far as practicable," was the present-value method for operating properties considered as covering the "available coal"—defined as that to be mined in forty years. Other coal was classed as reserves.

This Engineers' Committee used data available from the records of the Federal Trade Commission and the Geological Survey, and that material collected by the Coal Commission which was available when their study was made, in the late summer.

The report on valuation in detail follows:

Basis of Valuation.—The weighted average of data for the years 1920 and 1921, where such is available, was used as a base; first, because this was believed to fairly represent present conditions; second, any changes of conditions in costs would, we believe, be reflected in the realization; third, the data in the possession of the Commission is most complete for those years. Where the 1920-21 earnings were unavailable or misleading the most reliable available data was used.

As the total value of the properties is desired, costs are figured before royalty, depletion, depreciation and interest charges. Royalty in the case of leased and depletion in the case of fee lands represents the value of the undeveloped coal in the ground, depreciation the value of improvements and developments, and interest charges and profits the returns to capital used in operation. Federal taxes are a charge against income and must be deducted from the realization before it can properly be used in estimates of value.

Future tonnage is estimated from consideration of past tonnage and of reserves in each district.

Value of Operating Property.—From the above the value

of the operating properties is determined by discounting at 6 per cent compound interest the net yearly returns, as a varying annuity estimated for each field for the period noted, the latter obtained by applying the values as above indicated, per ton to the estimated tonnage for each year.

Value of Reserves.—The reserve tonnage is determined by the difference between the operating tonnage as above and the total estimated tonnage in each field. This is considered as a whole in each field as undeveloped coal and its value is based on either actual sales or virgin areas where such values of recent date are available and sufficient to justify their general employment in the estimates, or, lacking that, on the present value of the reserve coal at the present rates of royalty, but considered deferred for the life of the operating lands.

Total Valuation.—Based on the above the total valuation is made up of the value of operating coal land and reserves, including development and equipment, as well as all land values, regardless of whether the ownership is in the operating company or the lands are operated under lease.

Anthracite Situation.—Reasonably complete data, as requested, were furnished by your statisticians, together with the Commission's estimate of coal.

Estimated Reserves of Anthracite

Field	(In Gross Tons)		Recoverable Coal Remaining
	Total Coal Remaining	Per Cent Recoverable	
Northern.....	3,276,763,000	67	2,195,431,000
Eastern Middle.....	248,628,000	69.4	172,548,000
Western Middle.....	3,573,025,000	58.1	2,075,928,000
Southern.....	9,256,260,000	49	4,535,567,000
Totals.....	16,354,676,000		8,979,474,000

From a study of past production we estimate as a conservative basis of value that the field as a whole can increase its output by 1935 to about 100,000,000 gross tons per year, and hold this average production to the end of the 40-year period allowed for available coal.

The reserves, mostly in the Western Middle and Southern fields, are expected to maintain an annual output of 100,000,000 tons for about ten years longer and then gradually decrease to 50,000,000 tons per year with a total life of about seventy years additional.

As important factors in production we estimate for the Northern field a life of fifty years, for the Eastern Middle thirty-five years, the Western Middle 100, and the Southern field 110 years. All of these fields, of course, will produce coal long after the above limits, but in small quantities and of negligible present value.

The Western Middle and Southern fields will have to carry on after the other two fields cease to be important factors. Owing to depth and to geological conditions which cause a much smaller percentage in production of domestic sizes, the coal from these fields is more costly to mine and brings a smaller realization on all sizes. As a natural consequence these fields are developed only to supply the surplus demanded by the market over that furnished by the cheaper Northern and Eastern Middle fields. These more costly fields have the greatest reserves, however, and can be expected to maintain a large production long after the more favored fields are exhausted.

The average royalty paid on all coal sold was found to be 16.5c. per ton, the average depletion 14.7c., and average depreciation charged on plant 10.8c. Valuing the available coal, plant and improvements on the basis of the returns

Estimate of Present Value of Coal Lands, Plant and Improvements, in the United States

State	Net Tons		Estimated Present Values		
	Available for Mining Within 40 Years	Reserves of Present Value after 40 Years	Available Tonnage, Including Plant and Improvements	Reserve Tonnage	Total

Pennsylvania-Anthracite	3,907,900,000	5,071,600,000	843,500,000	146,400,000	989,900,000
Grand total	35,907,900,000	1,598,221,600,000	\$7,129,714,000	\$5,303,050,000	\$12,432,764,000

* Miscellaneous includes Arizona, California, Georgia, Idaho, North Carolina, North Dakota, Oregon, South Dakota.

in the Commission's figures, discounted to the present time, and the reserves on probable margins deferred forty years, we estimate the present value of the properties comprising the Pennsylvania anthracite field as follows:

Available recoverable tonnage	3,907,900,000
Reserve tonnage	5,071,600,000
Total tonnage	8,979,500,000
Present value of plant, improvements and available tonnage	\$843,500,000
Present value reserve tonnage	146,400,000
Total present value	\$989,900,000

Bituminous Valuation.—In appraising bituminous coal your committee, in addition to considering recent earnings submitted, has given full consideration to all data available on earnings of earlier years, sales values, royalty rates, past performances, and present estimates of tonnage and value, which it believes to be most conservative and fully justified by the data obtained.

The total tonnage is based on estimates of the U. S. Geological Survey and of various state surveys, all revised and reduced to allow for losses in mining and for thin and unavailable coal. The total tonnages considered in the committee's estimate are actually materially less than half of the tonnage estimated by the U. S. Geological Survey as remaining at the end of 1920.

"Available coal" is estimated as that commercially minable within forty years, allowing for probable gradual increases in the rate of output to a total for the whole industry of 1,000,000,000 tons per year at the close of the 40-year period. "Reserves" are considered as such coal as would be available after the exhaustion of the "available" coal, excluding from any consideration all coal so situated as to be impracticable of access, and all coal so thin or of such depth as to have no present sale value.

In determining the amount of reserve coal an effort has been made to confine this item to coal which at the present time, or at least within the 40-year life of the "available" coal, would have actual ascertainable sale value, and be capable of beneficiation.

As the values of "available coal" were obtained by discounting probable earnings, these values necessarily include all working capital, plant, development, equipment, mine housing and other properties directly connected with the business. They do not include outside factors, as interest or rentals received, profits from connected undertakings as stores, farms, selling of purchased coal and the like. The values of reserves are those of the coal land only, which in general are far below the market price of

similar lands in the same localities. It is the feeling of your committee that all the coal to be mined within forty years, whether from present or future operations, is included in "available coal" and that all reserve values should be treated as deferred.

The committee's estimate of the value of the coal properties of the country, not including coal in Alaska or in the island dependencies of the United States, is as shown in the accompanying table.

The value of the available tonnage, \$7,129,714,000, is the minimum on which earnings should be based. Considerable amounts of reserve tonnage are and should be held by operators to protect their future interests, and earnings must be sufficient to cover the carrying of reasonable holdings of such reserves.

Plant.—The data presented are not sufficient to permit the determination of the actual value of plant and equipment, nor do we believe that it would be possible to obtain data on that subject that would be sufficiently accurate to warrant its general application. The total value of plant and equipment in the bituminous fields varies from \$1 to about \$3 per ton of annual output; in the anthracite region of Pennsylvania it is from \$1.50 to as high as \$4.50 per ton of annual output. Employee housing of good type costs, under present conditions, from \$1 up per annual ton.

Your committee, having endeavored to be distinctly conservative in estimating both tonnages and values, desire collectively and separately to express most forcefully the opinion that the properties valued either as "available" or "reserve" could not be purchased in the open market except at a price far beyond the committee's estimates. The discount rates used—6 per cent for anthracite and 8 per cent for bituminous—are those adopted by the U. S. Treasury Department for income tax valuations.

Assigned-Car Order Now Set for Jan. 1

The Interstate Commerce Commission on Nov. 9 announced a further postponement of the date on which its order in the assigned coal car case becomes effective, fixing the new date as Jan. 1.

The order was to have become effective Dec. 1, but now it will not become effective until Jan. 1. Argument on the rehearing in the case will be heard Dec. 17, 18 and 19. It is regarded as probable that another postponement of the effective date of the order will be made prior to Jan. 1 because of the probability that the commission will not have reached a final decision on the rehearing.

Decisive Action Only Hope of Coal Trade Against Federal Control

Congress Leaders Ready to Push Legislation Sought by Coal Commission—Wadleigh Retirement a Setback—Commend Hoover Policy

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

In the message which he will read to Congress less than three weeks hence the President is fully expected to urge the translation into legislation of the recommendations of the Harding Coal Commission. Administration leaders in both Houses are known to be ready to expedite such legislation. It is improbable that there will be opposition to this legislation from the Democrats as a party; the opposition will come from certain individuals in both parties. There is little likelihood that the coal legislation will be regarded in any way as a partisan matter.

It is known that a considerable number of the members of both houses are willing to go much further in the matter of regulation than the Coal Commission has suggested. In fact, the whole drift is toward federal regulation and away from self-regulation in the coal industry.

The coal industry is not aware, perhaps, that it is under the closest surveillance on the part of certain legislators. It is true that these men probably favor federal regulation, but they recognize that the one thing which can weaken support for regulatory legislation is determined action on the part of the industry itself, not only in the matter of the voluntary publicity pledged to the Coal Commission just prior to the conclusion of its work but along the lines of broad activities.

Two recent developments have done much to discourage action on the part of the industry. One was the striking unfairness of the Federal Trade Commission's report on anthracite. The other was the resignation of F. R. Wadleigh from the position of chief of the Commerce Department's Coal Division. The coal industry had faith in Mr. Wadleigh and was willing to embark on co-operation under his guidance. Time now is being marked until his successor will have been appointed. Neither the National Coal Association nor the American Wholesale Coal Association has named its members to serve on the Coal Division's advisory committee. If Mr. Wadleigh's resignation halts the mere naming of members on a committee, it is certain to hold up the formation of an actual plan for the voluntary submission of cost and wage data.

The unfortunate Federal Trade Commission incident gives ground for the industry to say that it always is abused and double-crossed by the federal government. It supports the position of those who are willing to go to the mat with the government on the whole question as to whether or not the government has the right to exercise any degree of control over private business activities—and many operators believe that the production of coal is entirely an intrastate activity, into the conduct of which the federal government may not legally pry.

Another influence which is working toward federal regulation of the coal industry is the apparent determination of the Department of Justice to hamstring trade associations. Its recent course in the case of the United States versus the Tile Manufacturers' Credit Association, in which the department is forcing an agreement that statistics of production, stocks and other things may be collected only at the request of a government agency, is frightening members away from these associations. Statistics such as trade associations collect are essential to business. Congress, recognizing that point, is likely to look with favor on compulsory returns to a government agency.

There are many who think industry should rally to the support of the policy followed by Secretary Hoover. He has urged the capitalization of the constructive forces within industry. He would encourage the forward-looking and the honest to put into effect voluntary efforts which

would curb dishonest or gouging practices. He believes 95 per cent of the activities of trade associations are constructive and in the public interest. Unquestionably he regards regulation as a depressing and non-constructive step. It does not educate and encourage. It simply says: "Thou shalt not."

There are many who are wondering why the coal industry is allowing itself to drift at this critical time. No headway has been made in the simple matter of transmitting certain summaries of costs. There is a feeling in Washington that the coal industry would be well advised to get in touch with Secretary Hoover to see if more could not be done by way of expansion of the Coal Division so that studies could be made, in co-operation with industry, of the various suggestions made by the Coal Commission. It might be established that some of them are not practical. In other instances studies might be made which would be of benefit to the public and to the industry alike. The retailers might go to Mr. Hoover and suggest that he set up a section of the Coal Division which would study some of their problems. The wholesalers might do likewise.

Trade Commission Blames Wholesalers and Operators for High Anthracite Prices

Wholesalers who take exorbitant margins and operators who charge the wholesalers high prices are to blame for present "premium" prices that the public must pay for anthracite, according to a report issued Nov. 11 by the Federal Trade Commission. In the course of the report, the commission cites recent profits of \$1.50 and \$1.75 per ton on anthracite by wholesalers compared with pre-war margins of 10 to 15c. per ton.

"High prices exist in the wholesale trade either because they are charged by producers, or because of high margins taken by wholesalers," says the report. "At the present time they are due to both causes. About 25 per cent of the tonnage is being sold by the producers at 'premium' prices ranging from \$9.85 to \$12.25 per gross ton f.o.b. mines for domestic and from \$6.75 to \$9 for pea coal. Much of the anthracite sold at these prices goes directly from the producer to the retailer or consumer, but a part passes through the hands of wholesalers."

Figures for gross tonnage would be larger in the report, says the commission, if it were not that "a considerable number of wholesalers, including some of the largest, reluctant to let the public know what prices and margins they are realizing, have refrained from making reports." The commission reports that as a result of this failure to obtain facts, it is employing its coercive powers.

During the week ended Oct. 13 the highest margin taken by wholesalers reporting sales of anthracite at \$10 or more per ton for nut and larger sizes and \$8 for pea coal, was \$1.75 per gross ton, taken on six cars sold at prices ranging from \$12.75 to \$13.75 per ton. In the following week the highest margin was \$1.50 per ton taken on two cars sold at \$13 and \$12.75 per gross ton f.o.b. mines, respectively. Over against these high figures, during the week ended Oct. 13 six cars were sold at purchase price, one was sold at 50c. less, two at 75c. less, and one at \$2 less than purchase price per ton. During the week ended Oct. 20 four cars were sold at purchase price and two at 25c. less than purchase price.

Presenting details on profits, the commission says:

"The exorbitant character of the higher margins can only be realized by a comparison with pre-war and war-time gross margins.

"Prior to the war the customary wholesalers' gross margin on domestic sizes of anthracite was from 10 to 15c. per ton, while during the war the Fuel Administration allowed 20c. per ton east of Buffalo. The U. S. Coal Commission, in its report on the wholesale and retail coal trade, shows that for the four years immediately preceding 1917, the average rate of return on investment for wholesalers, handling anthracite only, ranged from 12.5 to 27.5 per cent, while during 1918 they made over 25 per cent.

Commerce Commission Broadens Rate Probe; Soft Coal and Coke Included in Inquiry

The Interstate Commerce Commission on Nov. 9 broadened its order to investigate freight rates for anthracite to include rates on bituminous and semi-bituminous coal and coke from points in Virginia, West Virginia, Kentucky, Ohio and Pennsylvania to points in New England, New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia and the District of Columbia.

The order was entered, the Commission said, because of complaints of shortage of fuel for domestic and other uses in the New England States and other states included in the order and that it decided the scope of the inquiry should be enlarged "in order that the Commission may elicit information sufficient to enable it to take appropriate action to require the establishment of railway routes and reasonable rates that will insure transportation of an adequate supply of fuel to the destinations indicated."

Following hearings in Rochester and Albany, the first of last week, Chief Examiner Butler moved to New York, where on the 9th two sessions were held at which a few witnesses were questioned. Attorneys for the railroads were on hand to defend the present rates. A representative from the State of North Carolina, another the Chamber of Commerce of Trenton, and the Secretary of the Long Island Coal Dealers' Association were the principal witnesses, Mrs. Louise Reed Welzmilller, Deputy Commissioner of Markets, represented New York City.

The hearings were scheduled to be continued in Philadelphia on Nov. 13 and in Washington on Dec. 3.

Signs Decree Separating Lehigh Valley Railroad and Coal Properties

Segregation of the Lehigh Valley R.R. Co. from its coal properties is ordered in a final decree signed Nov. 8 by Judge Learned Hand in the U. S. District Court at New York City. It provides that the railroad shall dispose of all shares of stock, bonds and other evidence of indebtedness as is necessary to establish its entire independence of and from the coal companies. There remain the agreement as to trustees under the plan, the preparation of the stock and the necessary agreement of 85 per cent of the stockholders to the assessment of \$1 levied for exchange of the stock.

The decree directs that the Lehigh Valley R.R. Co. shall, subject to the lien of its general consolidated mortgage, sell, assign and transfer its entire right, title and interest in and to the stock of the Lehigh Valley Coal Co., including the present right to vote and receive dividends thereon, to a trustee to be appointed by the court, but meanwhile, pending the appointment of a trustee, the coal company may pay the railroad company a cash dividend. The amended plan provides that the rights for subscription by Lehigh Valley R.R. stockholders for certificates of interest be extended until April 15, 1924.

Shareholders who buy certificates in the coal company must dispose of them before Dec. 31, 1927, if they have not in the meantime disposed of the railroad stock. If they have not done so the certificates will be called and the subscription price of \$1 a share refunded. The plan provides that neither the railroad company nor any corporation controlled by it shall acquire any coal stock.

The Lehigh Valley R.R. Co. shall transfer to a trustee to be named by the court its right, title and interest in the stock of Coxe Brothers & Co., Inc., the trustees to hold said right, title and interest in said shares of stock until the maturity of the collateral trust agreement on Feb. 1, 1926. The amended plan further provides that the railroad shall transfer to a trustee its right, title and interest in the stock of the Delaware, Susquehanna & Schuylkill R.R. Co., to be held until the maturity of said collateral trust agreement.

One of the most interesting points made by Judge Hand was that "It will not constitute a contempt of this decree for the Lehigh Valley R.R. Co. to apply to the Interstate Commerce Commission for leave to retain the stock and to

lease the property of the Delaware, Susquehanna & Schuylkill R.R. Co. or to merge and consolidate that company, provided that this provision shall not be construed as the expression by this court of any opinion as to the propriety of granting said application."

Another provision of the amended plan points out that "the Lehigh Valley Coal Co. and Coxe Brothers & Co., Inc., on the one hand, and the Lehigh Valley Coal Sales Co. on the other, their officers, directors, agents, servants and employees are hereby perpetually enjoined from further carrying out the contract dated March 1, 1912, cancelled and annulled by the decree or mandate entered by this court on Feb. 24, 1921, and from entering into any like contract in the future, the purpose and effect of which would be in any manner to hinder or restrain the Coal Sales Company from extending its business of buying and selling coal where and from and to whom it chooses with entire freedom and independence, or otherwise to violate the spirit and purposes of this decree."

Judge Hand further exhorts the parties to the decree to move with "due diligence" to carry out the provisions of the decree and asks that a written report of progress be handed to him within six months from the date of the decree.

Terre Haute Wants Mine-Rescue Station; Vincennes Team Slow at Hunt Fire

Federal aid in the establishment of a mine-rescue station in Terre Haute is to be sought, as a result of the tragedy at the Hunt mine, near Staunton, Saturday, Oct. 27, in which four lives were lost. Mine Workers' officials and Indiana operators expect to co-operate in backing a bill to be introduced by Representative Everett Sanders providing for an appropriation for this purpose.

Attention is called to the fact that the entire northern portion of the Indiana bituminous coal field has its center in Terre Haute and that with the paved highways radiating from there to all mines in the territory, they can be reached quickly. The nearest station at the present time is located at Vincennes.

Phil Penna, secretary of the Indiana Bituminous Coal Operators Association, and John Hessler, president of District No. 11, U. M. W., both issued statements that their organizations have always favored the location of such a station in Terre Haute and would assist Congressman Sanders all they could.

Much criticism was heaped upon the rescue team at Vincennes for its performance at the Hunt mine fire. Not only did the team require a long time to reach the mine but it used up so much time getting ready to enter that miners and firemen from Terre Haute and Brazil went in and brought out three of the four bodies.

Utilities Coal Consumption Drops Slightly In September; Power Output Gains

Electric public-utility plants consumed 3,182,075 net tons of coal during September, according to a report just issued by the U. S. Geological Survey. This compares with 3,211,124 tons consumed during August, according to corrected returns.

Fuel oil consumed by public-utility plants in September totaled 1,352,933 barrels, compared with 1,352,299 barrels in August. The average daily production of electricity by public-utility power plants during September was 152,400,000 kw.-hr., compared with 150,800,000 kw.-hr. in August.

Stockholders of the Philadelphia & Reading Coal & Iron Co., the stock of which is owned by the Reading Company, at a meeting held on Nov. 8, approved of the segregation plan in so far as it affects the coal company, including the creation of a new mortgage, under which bonds will be issued in exchange for the coal company's one-third proportion of the present general mortgage. The plan has been filed with and accepted by the U. S. District Court at Philadelphia.

Production and the Market

Weekly Review

The bituminous coal market, in regard to both production and prices, continues to drag along week after week with no change. Accounts in several newspapers on Monday of this week portraying the operators and union miners girding their loins for a big scrap next spring may have been inspired by the hope that the consumer could be scared into buying more coal. According to the estimate of the Geological Survey the consumer for the past twelve months has been buying more than he burns and there is nothing to indicate that he can be induced to increase his rate of purchase. Stocks of soft coal in the hands of industrial consumers and railroads are now well above the average for this time of the year. The bulk of the soft coal produced continues to move forward on contracts at prices \$1 to \$1.50 above the spot market.

Coal Age Index of spot prices of bituminous coal gained one point last week, reaching 184 on Nov. 12. This corresponds to the average weighted price of \$2.23 per net ton at the mines. Anthracite prices are holding firm, independent quotations of around \$12 at the mines being not uncommon for stove coal.

OUTPUT AND PRICES UNAFFECTED BY SHUTDOWNS

Reports from all sections are to the effect that more and more mines are being closed. These mines in part are those of large companies, which are shutting high-cost operations and increasing the activity of their better mines. So far the number of mines shut down has not been sufficient to affect production or influence prices.

The resolution passed by the Smokeless operators, opposing wage reductions is expected to influence other non-union fields to take the same course. The Interstate Commerce Commission, by opening up the anthracite rate hearings to let in the West Virginia smokeless shippers is believed to have acted in conformity with the general policy of the administration, which is to

encourage the use of substitutes for anthracite. These shippers would have an all-rail rate to Boston from southern West Virginia, or such improved dumping arrangements at Hampton Roads as will not break up their coal.

Shipments of smokeless coal to tidewater were temporarily checked by the strike on the Virginia Ry. last week, but there continues to be an abundance of coal

	Week Ended Nov. 5	Season to Nov. 5
Cargo	1,044,495	26,535,176
Fuel	43,609	1,433,363
Totals	1,088,104	27,968,539

available at Hampton Roads. New England is taking most of her industrial coal by water, which is assisting in keeping up the tidewater business. The Lake movement continues heavy and it is now expected that all records for bituminous coal movements over the lakes will be broken this year.

Demand for domestic sizes of anthracite is heavy. More Welsh anthracite is on the way to these shores and is expected to arrive during this month. Production of hard coal during the week ended Nov. 3 is estimated to have been 1,373,000 net tons, by the Geological Survey, a drop of 696,000 tons from the previous week.

Estimates of Production

(Net Tons)

BITUMINOUS

	1922	1923
Oct. 20	10,378,000	10,694,000
Oct. 27 (a)	10,683,000	10,919,000
Nov. 3 (b)	10,666,000	10,560,000
Daily average	1,778,000	1,811,000
Calendar year	322,588,000	467,300,000
Daily av. cal. year	1,237,000	1,795,000

ANTHRACITE

Oct. 20	2,039,000	2,045,000
Oct. 27	1,836,000	2,069,000
Nov. 3	1,872,000	1,373,000

COKE

Oct. 27	237,000	276,000
Nov. 3 (a)	213,000	269,000
Calendar year	5,804,000	15,929,000

(a) Subject to revision. (b) Revised from last report.

There were dumped for all purposes at Hampton Roads during the week ended Nov. 8 225,627 net tons of coal, as compared with 344,120 tons the previous week.

Midwest Market Lower

Nothing happened during the past week to relieve the market monotony of the Midwest. Almost all coals droned along at a little less than the pace of the week before, with lump and egg from Illinois and Indiana holding practically the whole domestic trade of the region against "foreign" coals, but with steam trade dragging screenings prices down a shade. Production has slowed down a little more to meet this situation, however, so that the small volume produced in Illinois and Indiana has kept domestic prices fairly stable.

Southern Illinois lump goes for the market price of \$4@ \$4.35, Central Illinois lump for \$3.25 and Indiana Fourth Vein for \$3.25. A steady flow of anthracite into the Chicago region continues at the standard mine prices, but smokeless and other Eastern domestic coals are having a hard time West. West Virginia smokeless mine-run has

dropped to \$2@ \$2.50 and lump and egg is down a dollar to \$5@ \$5.25 with only moderate demand for it at any price.

Southern Illinois Fields Inactive

There is little activity in the movement of anything from the southern Illinois field. Some mines are able to keep their lump moving, but are unable to move the other sizes. Several of them have no bills of all sizes. Railroad tonnage has slowed up during the last week, and there is general discouragement over the entire field. Independent mines seems to get the fast working time, while the Association operators still maintain their prices.

In the DuQuoin field conditions are bad. Some mines are idle altogether, as is the condition in the Cartersville field, but prices are practically equal to those of the independent Cartersville operators and it is hard to move anything. In the Mt. Olive district a little domestic tonnage is moving, but it is under pressure, and there is no place to put steam sizes. A car shortage prevents certain mines from working, while they have no bills on hand and, generally speaking, conditions in this field are bad. The Standard district is plugging along, selling coal in some instances

Index	1923				1922
	Nov. 12	Nov. 5	Oct. 29	Nov. 13	
Weighted average price	\$2.23	\$2.21	\$2.23	\$4.12	

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

below cost. Steam is the hardest size to move but even 6-in. lump, which moves the easiest, is frequently noted among the no-bills.

St. Louis Trade Still Quiet

Mild weather continues to maintain a soft market in St. Louis. The general condition is discouraging. Many oil burners have cut into the demand for better grade coals. The little tonnage that is moving is of the middle and lower grades and while there has been some movement the past week, it is in small quantities. Anthracite trading is light in comparison with past years. Coke and smokeless are not factors. Country domestic business is slow and calls for cheaper grades only. Country steam is hard to find, although a little movement of steam egg and nut has been noted to Omaha, Minneapolis and Chicago. Wagonload steam seems to maintain its own, but everything is far below normal.

Kentucky Market Unsettled

Although lower markets on prepared coal had been anticipated over the week as a result of cessation of Lake shipping, cool weather has created a better demand for prepared sizes from retailers, while potteries have been operating at capacity, and general consumption has been fair, with the result that prices are holding, and in fact are a shade

stiffer in western Kentucky, where there is an effort to advance lump from \$3 to \$3.25. Steam prices continue low, and with production of prepared at its present level there is not much prospect for a good price for steam coal or screenings at this time.

The general market shows little change over levels in effect over the past two or three weeks. Railroad reports show full car supply on all western Kentucky divisions, and eastern Kentucky is not complaining.

No general reductions in wage scales in eastern Kentucky are expected before April 1, but a few scattered operations are now on the 1917 wage scale, and are producing some cheap coal that will be a mean factor in competitive selling, and which may force numerous other reductions. Most of the reductions in eastern Kentucky and Tennessee have been in small mines.

Northwest Trade Is Moderate

Coal trading continues fair throughout the Northwest but without excitement except a little that is stirring up over a possible slight shortage of anthracite in the northward regions. Hard-coal receipts at Duluth-Superior have not been as heavy as expected for the past three weeks and it now appears the country trade has bought up about all there is on docks. In spite of high prices, this is stimulating the hard-coal market.

Anthracite shipments have been made to the Dakotas, western Minnesota and some points in Canada from Duluth and more orders have been accepted and will leave the docks before the closing of navigation. The Duluth market is fairly well depleted and two docks have stopped local sales of stove and nut. Most of the docks are not taking orders for car lot shipments of anthracite from outside points.

Receipts at Duluth-Superior up to Oct. 31 are as follows: Hard, 1,179,779 tons; soft, 9,691,680 tons; total, 10,871,459 tons. The increase as compared with last year's shipments to the same date are: Anthracite, 925,280 tons; soft, 6,187,492 tons. The average receipts to Oct. 31 over six years is 7,924,492. In all, twenty-four cargoes of hard and 168 cargoes of soft coal have arrived.

The Milwaukee coal market is quiet. Jobbers and retailers report little doing and a minimum amount of fuel is being consumed. Coke and the domestic grades of soft coal are the best sellers since anthracite has been lifted to the luxury class. Coal is coming freely by lake. The average receipts during the first five days of November were 40,312 tons per day. November receipts thus far aggregate 37,300 tons of anthracite and 205,156 tons of soft coal, making the season's receipts to date 821,624 tons and 2,802,857 tons, respectively. The dock yards are nearly filled to capacity with soft coal. Prices remain unchanged.

Western Trade

There was little life in coal trade throughout the West and Southwest during the week beyond the fact that steam trade began picking up in and around Kansas City, and Kansas lump, after a long period of slow running time at the mines, was able to raise its top price from \$5 to \$5.25. There are fewer no-bills in the Kansas and Oklahoma fields just now. Most mines get about 50 per cent of full time.

In Colorado there is a slight stimulation of domestic trade by reason of cool weather and the demand for steam coal has come up slightly also, but the whole effect has been small on production and running time. In Utah trade is quieter than it has been for weeks. The last vestige of car shortage which afflicted a few operations a little a couple of weeks ago has passed and now there is no need for many of the cars available. Running time averages little over two days a week. Stocks of all sorts of coal are rolling up.

Ohio Buyers Limiting Purchases

Buying of both domestic and steam coals is limited to immediate wants in the Columbus market and there is little disposition to buy for the future. On the whole the trade is quiet. Retail stocks of domestic coals are fairly good, and while this trade probably is the best feature of the market, it is not as active as a few months back. West Virginia

splints and Pocahontas are in best demand for domestic use and there also is a fair demand for Pomeroy, Crooksville and Cambridge grades. The steam trade at Columbus is quiet, as reserves are heavy.

In the Cincinnati market cool weather failed to arouse the market materially. Domestic coals move slowly and slack is hard to place at almost any price. Consignment and distress coals, which were so prominent in this market a few weeks ago, have been pretty well cleaned up. The under-current in the low-volatile market seems to be the point of interest now. There are reports that large tonnages are being moved at \$5 or less, but these sales are not being acknowledged by the companies. Quotations for West Virginia and southeastern Kentucky 2-in. lump range from \$2 to \$2.50.

Reports from the Cleveland market are pessimistic. Industrials are not inclined to add to their already heavy reserve stocks and inquiries are not numerous. The retail dealer is not reporting the usual activity.

Very little distress coal is to be had in the Pittsburgh market, and the coal now being offered at low prices, below what operators claim is the real cost, is nearly all fresh-mined product. Production in the Pittsburgh district continues to decrease, as one mine after another closes on account of having completed its lake shipments. It was expected that the closing of mines would improve market conditions, but as the market has not stiffened it is assumed that other mines have not completed their lake deliveries and are still offering coal in the spot market.

There are few signs of improvement in central Pennsylvania. Producers say there is no business to be had and the mines are working two or three days a week, while many of the smaller operations are closed down.

New England Quotations Lower

In New England quotations for spot coal are even lower than a week ago. Aside from distress coal, No. 1 Navy standard Pocahontas and New River are rumored to have been sold within a few days at less than \$4.25 f.o.b. vessel, Hampton Roads. On cars Boston there have also been sales at correspondingly low figures. On mine run, \$5.18 and \$5 have been named, and slack has been disposed of at more than 50c. less. It should be said, however, that receipts are running less than they were, and judging from the number of operations that have closed down the past week it is expected the latter half of the month would make November totals very much less than figures for October.

On all-rail from Central Pennsylvania there is almost nothing doing in this territory. A few scattering sales are made in areas west of the Connecticut River, but from there east there is practically no outlet for anything but tide-water coal.

Reserves are heavy, and it will be interesting to watch the course of the market during the next few weeks. There are some who think there will be no pronounced turn for the better until January, when possible labor complications may begin to loom up.

Less Coal at New York Tidewater

Slowing up of shipments to the New York tidewater resulted in a partial cleaning up of loaded boats and distress coal. Demand did not improve, however, and shippers had

to keep busy in order to move their supplies. Tenders received last week by the U. S. Shipping Board for delivering alongside vessels, New York harbor, 2,000 gross tons Pool 9 bituminous coal, resulted in prices ranging from \$4.21 to \$5.47, as compared with \$4.18 to \$5.25 submitted about ten days previously. There is no improvement in the Philadelphia market and some interests believe there has been a shrinkage in business moving for the last three weeks. The consumer is indifferent. Several important jobbers at Baltimore report getting inquiries involving large tonnages and it is said some important closings were made. One of the disturbing elements has been reports of bad preparation.

More mines are closing down in northern and southern West Virginia. Demand continues slow, although cool weather created a little better call for screened coals and stiffened the price slightly, but the increase was not general. No-market losses are reported as large in the southwestern Virginia fields.

Conditions at Birmingham are not promising. Inquiry and new business is confined to spot sales. Sales of domestic grades are fairly good, while production is being closely confined to trade requirements. There has been a marked decrease in iron production and consequently less demand for furnace coke, while the market for foundry coke is quiet and easy.

Welsh Anthracite for New England

The situation in New England with regard to anthracite is in a fair way to be relieved slightly by the arrival of about 30,000 tons of Welsh anthracite, which will be brought to these shores this month and landed at Boston, Providence and Portland. Some of this tonnage is now on the way. Activity continues to be confined to the domestic sizes. Demand is active and retail dealers desire larger shipments. Egg and pea coals are the easiest in supply, but there is no surplus of either size.

Stove and chestnut sizes are most in demand in New York and Philadelphia, and retail dealers say they are not receiving enough of these coals to take care of their trade. Dealers at Baltimore are disappointed over the lack of shipments but are able to take care of emergency orders. However, while there is a considerable tonnage of unfilled orders on the books, practically all consumers have been given some coal. Demand for anthracite at Buffalo far exceeds the demand, but shippers there are not disturbed over the situation, for they believe there is going to be coal enough to go around.

The steam sizes move slowly. Considerable storing is being done by both the larger producers and some independents. In many instances retail dealers are taking car for car of the smaller coals in order to get the domestic sizes, and in some cases are able to get the larger coals at lower prices but are quoted slightly higher prices for the smaller coals.

Foreign Market And Export News

British Coal Consumers Close Contracts; Output Declines Slightly

There was a decrease of 5,000 tons in the production of coal in Great Britain's mines during the week ended Oct. 27, as compared with the previous week's output, says a cable to *Coal Age*. The output was reported as 5,675,000 tons as against 5,680,000 tons the previous week, while the production for the corresponding week of 1922 was 5,388,000 tons.

Though the Welsh coal market has not improved materially it is understood that a number of large consumers have contracted for coal for the early part of next year. The tonnage involved was not announced but it is understood to aggregate about 500,000 tons and that the prices accepted range from 6d. to 1s. over last year's contract figures.

Several small orders have been placed for Admiralty large steam, at a slight advance in price, but as operating and labor costs have also increased the benefit of the advance is not felt.

One company has sold between 100,000 and 150,000 tons of machine-broken anthracite cobbles and nuts to America and Canada. It is understood that this same company has arranged for the installation of breaking plants at New York, Montreal and Quebec.

Welsh operators are expecting the French, Italian and German demands to increase during the winter months.

The Newcastle market is still in a strong position and no anxiety is felt over business during November. Various contracts are reported for lots of 10,000 to 20,000 tons for delivery over next year, and 30,000 best steams at 24s. 6d. per ton for January-February delivery. Tenders have been cabled for 25,000 tons of steam coal for the Norwegian State Railways.

Hampton Roads Dumpings Decrease

Business at Hampton Roads did not improve last week, while dumpings for the week ended Nov. 8 amounted to 225,627 net tons, a decrease of 118,493 tons when compared with the previous week. Coastwise trade and bunkers constituted the bulk of the business, with the former showing signs of increasing.

The strike of the Virginian railway engineers caused a complete tie up at the piers of that road at Sewalls Point, with a consequent strengthening in the coal market, but which was regarded as temporary. The effect of the strike was not felt as it would have been at any other time of the year, because the demand for coal was not brisk.

There is less stringency in the domestic coal business than has existed at this period for the last two years, because consumers appear to be content to confine themselves largely to soft coal, of which there is an abundant supply. The tone of the market was somewhat stronger than for the previous two weeks.

"Popular" Coals for French Consumers

To combat the high cost of living the French authorities have asked retail dealers to make a special selection of coals to be sold as "popular" coals at reasonable prices. Due to mild weather demand for house coals is weak, otherwise the present supplies would soon be exhausted. Industrials coals are in fair demand.

Wage negotiations looking to a readjustment of miners' pay are now under way and it is generally believed that the workmen will secure some concessions.

Imports of British coal show a slight increase, but consumers are not inclined to make heavy purchases due to the condition of the money market.

France and Luxembourg received about 30,000 tons of indemnity coal during the period Oct. 11-20, 61,100 tons of coke and 4,900 tons of lignite, a total of 96,000 tons, as compared with 109,200 tons for the previous ten days. The Minister of Public Works who recently returned from an inspection of the Ruhr district, reports that actual daily shipments must not be expected to average more than 7,000 tons of coal and 3,000 tons of coke.

Imports of coal during September amounted to 2,619,831 tons as compared with 2,241,157 tons in August. This included 1,667,185 tons from

Great Britain and 41,768 tons from the United States. Exports during the same period was 171,853 tons, as compared with 185,725 tons in August. Coke imports amounted to 280,116 tons in September as against 274,606 tons in August, with exports of 49,944 tons in September as compared with 59,976 tons in August. Imports of patent fuel in September amounted to 46,374 tons and exports of 19,536 tons. In August the imports were 64,460 tons and exports 12,545 tons.

News Items From Field and Trade

ALABAMA

George Gordon Crawford, president of the Tennessee Coal, Iron & Railroad Co., has accepted the chairmanship of the State harbor board, created by an act of the recent Legislature to supervise the development of port and harbor facilities at Mobile, for which the state will lend its credit to the extent of \$10,000,000.

The **Pratt Fuel Corporation** has purchased the mineral lands and plants of the **Bryan Coal Corporation**, consisting of about 10,290 acres of valuable coal lands in Jefferson and Walker counties and a number of producing mines. The consideration is said to have been between \$600,000 to \$700,000. The acquisition of the new properties will give the Pratt Corporation a potential capacity of about 1,000,000 tons of coal annually. **Walter Moore** is president of the Pratt Corporation and also is vice president of the DeBardeleben Coal Corporation, formed several months ago by the merger of three independent commercial producing companies.

William Dockerty, foreman of No. 1 Pratt mine of the Tennessee Coal, Iron & Railroad Co., was **fatally injured** Oct. 27 when struck by a tram car in the mine. Mr. Dockerty had been identified with mining operations in the Birmingham district for many years and was widely known.

The annual meeting of the **Alabama Mining Institute** will be held Nov. 21 at the Roebuck Country Club. Officials will make report on activities of the Institute during the past year and officers and committees for the new year will be elected. The meeting will be addressed by **Harry L. Gandy**, of Washington, executive secretary of the National Coal Association, and possibly by President **Erydon**, the latter having been invited to be present.

ARKANSAS

Fire destroyed the tippie of the Mine No. 1 of the Southern Anthracite Coal Co. at Russellville, Oct. 16, causing a loss of approximately \$100,000.

Work will be started at once, it is understood, on the **rebuilding of the tippie and top works at the Bernice mine No. 1** of the Southern Anthracite Coal Co. which were recently destroyed by fire near Spadra, with a loss of \$100,000.

COLORADO

Fred Ewing recently with the National Fuel Co. of Denver is now associated with the **Ewing Fuel Co.** which includes Mr. Ross and Mr. Campbell. This company is in the brokerage of coal, handling **Ross Coal Co.**, anthracite from Crested Butte.

The **Midwest mine** located at Palisades, recently closed on account of explosion in which six men lost their lives, **has reopened** and is operated by the sons of **R. T. Scott** who formerly had the lease before the explosion.

ILLINOIS

The **United States Steel Corporation** has transferred to the **Burton Coal Co.** of Chicago its 3,000 acre tract of virgin coal land in **Williamson County**. This property, which has been held by the steel interests as a reserve for the future, will be operated soon by the **Burton Company**, through the **Freeman shaft** of that company on land adjoining. It is improbable that a new shaft will be driven.

The **Nason Coal Co.**, Chicago, announces the appointment of **John D. Ristine** as assistant to the vice-president, effective Nov. 15.

The **Southern Coal Co.**, 343 S. Dearborn Street, Chicago, has been granted a charter of incorporation by the Secretary of State at Springfield. Capital stock is given as \$50,000. The company will mine, buy and sell coal, coke, etc. Incorporators are: **Wil-**

liam G. Worthey, **Louis C. Horner** and **Joseph B. Lawler**.

INDIANA

Reductions in the price of domestic bituminous coal and coke ranging from 50c. to \$1.50 a ton have been announced by the Indianapolis coal dealers. This is the first time in 25 years that fall coal is cheaper than spring coal in Indiana. **Pocahontas** shoveled lump was reduced from \$11.50 a ton to \$10.50, **Pocahontas** mine run from \$9 to \$7.50 a ton. **West Virginia** lump from \$9 to \$7.75 and **Kentucky** lump from \$9 to \$8. **Coke** dropped from \$12.25 to \$11.75 a ton, and crushed coke from \$12.25 to \$11.75. **Linton Fourth Vein** forked lump was reduced from \$6.75 to \$6.25, and **Linton Fourth Vein** shoveled lump from \$5.50 to \$4.95 a ton.

After being entombed in the **Hunt Brothers' Mine** at **Staunton** for more than seven hours Oct. 27 the **lifeless bodies of three miners and a boy** were taken from the fire-wrecked mine. The bodies were removed by volunteer workers after an all-day fight to subdue the flames, which wrecked the interior of the mine following the explosion of a gasoline engine in the workings of the mine. The four victims of the explosion were: **John Landis**, 44, of near **Eagles**; **Peter Buttermann**, 45, **Brazil**; **Joe Hardy**, 65, **Turner, Ind.**, and **George Harvey**, 10-year-old son of **Joe Hardy**, who was spending the day in the mine with his father. Four other men were rescued shortly after the explosion, when a rope was let down the air shaft and they climbed to safety.

The **Burnett Mutual Mining Co.**, of **Burnett**, has been incorporated with a capital of \$50,000 to mine coal. The directors of the company are **Walter Foxworthy**, **J. L. Revonald**, **Ed Hoffman**, **Noble Christopher**, **Elmer Marquis** and **Fred Christopher**.

KENTUCKY

Underground coal-loading machines are coming into greater use in western Kentucky and several companies which haven't them have heard good reports concerning their operation, and are planning to install. **Western Kentucky**, a section of thick coal, can use loaders to advantage. While it is a union field, the union workers, although plainly showing that they do not care for labor-saving machinery, have used the machines and have not been directly hostile to the idea. **Eastern Kentucky**, a field largely non-union, contains a good many thin-seam mines, and it is contended that the coal-loading machine cannot be operated as well there. However, it is believed that eastern Kentucky in a number of instances will come around to loaders.

Amended articles have been filed by the **Wallins Creek Coal Co.**, Louisville, operating in Southeastern Kentucky, the capital being placed at \$150,000 and debt limit at \$500,000. **T. L. Young**, **L. H. Young** and **J. L. Laurent** are the incorporators.

Western Kentucky is feeling rather good as a result of a decision of the Interstate Commerce Commission placing the freight rate from western Kentucky to the Northwest on the basis of 25c. a ton over the rate from the southern Illinois mine group. The **Western Kentucky Coal Bureau** had been fighting for this rate for a year or more. The new rates go into effect Jan. 24, 1924.

It is reported that **J. D. Wheeler**, of **Pike County**, is one of the organizers of the **Barking Coal Co.**, a \$100,000 company, which will install a new operation in **Dickinson County, Va.**, on the **Carolina, Clinchfield & Ohio R.R.**, a few miles from the Kentucky border.

J. H. Sudworth, of **Central City**, has been appointed an assistant state mine inspector, to succeed **J. A. Lewis**, in the third state district.

There is no movement of river coal now, as the **Ohio River** is lower than within a period of 40 years or more.

MISSOURI

Missouri coal is becoming an important fuel source to industries within the state. There is an apparent notable increase in mining over the strike year of 1922. Coal lands are acquiring increased values. Public-utility plants in the state are not only using more Missouri coal than in the past, some of them have purchased and are operating their own mines, while others are seeking mines, according to the **Missouri Committee on Public Utility Information**. An electric light and power company is operating its own mines at **Clinton**. Another company has acquired mining rights to 60,000 acres of coal land near **Salisbury**. Coal mining at **Novinger**, **Kirkville**, **Bevier**, **Lexington**, **Richmond**, **Moberly** and **Fulton** has been greatly stimulated by the demand of public-utility plants for fuel, the committee states.

W. G. O'Fallon, fuel agent for the **St. Louis Terminal R.R. Association** for fifteen years, has resigned to engage in private business. During the strike in 1922 he was one of the four experts appointed by the **American Railway Association** to allocate railroad fuel when the situation was worst. His territory was the southwestern region.

C. B. Bee, chief rate expert for the **Public Service Commission of Missouri**, has resigned to accept a similar position with the **Oklahoma commission**, effective Nov. 1. He leaves for an increase of \$1,500 a year. The **Missouri salary** was \$4,200. He will be succeeded by **V. E. Smart**, traffic expert of the **Board of Railway Commissioners of North Dakota**.

NEW YORK

Charles S. Allen, who was secretary of the **Wholesale Coal Association of New York** and is now connected with the **Cory Mann George Corporation**, of **New York** and **London**, has been appointed manager of the office of the corporation recently opened in **Scranton, Pa.**

Robert L. Kyte, formerly with **Bulah Coal Mining Co.**, has become associated with **Fred D. Gearhart, Inc.**, of **New York City**, as combustion engineer.

M. A. Hanna Co. for the quarter ended Sept. 30, reports total net income of \$679,936 after interest, depreciation, depletion and federal taxes, equivalent, after allowing for preferred dividend requirements, to \$1.47 a share earned on the outstanding 282,844 shares of no par common stock. For the nine months ended Sept. 30, total net income was \$1,938,137, equivalent, after allowing for preferred dividends, to \$4.82 a share on common.

Colorado Fuel & Iron Co. for the quarter ended Sept. 30, 1923, reports a deficit of \$316,644 after fixed charges and depreciation, compared with a deficit of \$131,462 in the corresponding quarter of 1922. Gross receipts amounted to \$7,762,931, compared with \$7,266,964 in the 1922 period, while operating expenses aggregated \$7,096,421, against \$6,376,400. Non-operating income was \$105,365, compared with \$73,391 in the third quarter of 1922. Fixed charges, etc., were \$712,448 against \$719,407 and depreciation charges were \$382,671, compared with \$376,011 in the 1922 period.

Chas. A. Owen, **Howard Adams**, and **James E. Manter**, Receivers of the **Tidewater Coal Exchange, Inc.**, announce that **J. O. Wolcott**, Chancellor of the State of Delaware issued on Oct. 26 the following order in connection with the dissolution of the **Tidewater Coal Exchange, Inc.**: "It is hereby ordered that the time for filing claims against the said receivership estate be and the same is hereby renewed and extended until the 1st day of January, A.D., 1924, and the time for receivers and all other persons in interest to file exceptions to claims filed against said estate be and the same is hereby extended until the 1st day of April, A.D., 1924." Probated claims, the receivers say should be filed with the Register in Chancery, Wilmington, on or before Jan. 1, 1924.

OKLAHOMA

The **Oklahoma School of Mines** has established a branch school in **Henryetta**, to instruct miners in different phases of mine work. The school opened with 60 men enrolled. Under the direction of **W. E. Howard**, it will have three additional instructors. Classes will be held in the afternoon and evenings. The school is supported by an appropriation of both state and federal funds, and is open to any person more than 16 years old who is not a pupil in the city schools.

OHIO

The Tildesley Coal Co., of Cincinnati, has purchased the P M C mines at Sprigg, W. Va., on the Norfolk & Western Ry. and will operate them in their own interests.

L. C. Halloran, formerly connected with the mining side at Omar, W. Va., with the Main Island Creek Co., has become connected with the Universal Coal Co.'s Cincinnati office as a salesman in the Northwest. His headquarters will be in Chicago.

The Bethlehem Coal Co., Cleveland, has been chartered with an authorized capital of \$10,000 to operate coal mines. Incorporators are W. F. Maurer, T. B. Bolton, Norton McGriffin, L. M. Coolidge and E. H. Bevier.

R. N. Osborne succeeds W. W. Austin as secretary of the Borderland Coal Sales Co., of Cincinnati, and A. S. Bitters, for eight years with the Matthew Addy Co., has become the traffic manager and credit man for the Borderland.

The mine of the John Donald Coal Co., near Millersburg, which has been burning for several weeks, cannot be sealed up because of several holes burned through the surface which admits the air to the blaze underground. The mine, which was one of the largest producers in Holmes County, was set on fire by a stove used for heating purposes. Cave-ins, which have prevented the sealing of the mine, have occurred from time to time, and an attempt to flood the mine also failed.

The Penn-Ohio Coal Co., near Lisbon, is preparing to resume operation after several weeks' idleness to install modern electrical equipment. It is expected to produce 100 tons of coal a day.

PENNSYLVANIA

At the present rate of consumption, Somerset County, one of the leading bituminous coal counties in central Pennsylvania, will have coal enough to last 500 years. A statement issued on the coal reserves of Somerset County by the Pennsylvania Bureau of Mines discloses that there are 3,987,900,000 tons of unmined coal in the county. This area represents the largest reserve of high-grade low-volatile steam coal in the state. The Berwind-White Coal Co. mines are in that district. Approximately 8,000,000 tons of coal is produced annually in Somerset County, which is taken from at least eight mineable coal beds. The lower and upper Kittannings are the thickest and best beds, most of the present production being from these beds.

A conference was recently held at Harrisburg by Attorney General George W. Woodruff, Dr. Ellen C. Potter, Secretary of Welfare, and T. Henry Walnut, chairman of the State Workmen's Compensation Board, to consider a change in the ruling of the Workmen's Compensation Board made some months ago. This was that the maximum which any hospital may receive for medical, surgical or hospital treatment of an injured workman shall not exceed \$100. Dr. Potter contended that the ruling was most unfair to the hospitals as frequently the value of the services rendered for an injured worker is in excess of the maximum amount allowed. Full service is rendered, she said, but full payment cannot be collected.

Thomas Kennedy, president of District No. 7, United Mine Workers, in an address before the City Club, at Philadelphia, on Nov. 9 defended the coal miners' position and said that with reasonable profits for the coal operators, fair and equitable freight rates, elimination of unnecessary middlemen and a reasonable profit for the retailer, the price of coal could be reduced at least \$3.50 per ton. In his address and in meeting a fire of questions afterward, the speaker stoutly held to it that the miners' wages are only fair and reasonable, and not responsible for high prices. He lauded Governor Pinchot. "The governor and his advisers," he said, "in one week found out more about the operators and more facts about the coal situation than the Coal Commission found out in a whole year, with the expenditure of something like \$760,000.

Announcement has been made of the organization of a company which has taken a 99-year lease on a 371-acre coal tract near Pottsville, where bore-hole drillings are said to have shown coal of an excellent quality. The new concern is to be known as the Jordan Coal Co. with P. E. Jordan, of Scranton, as president. Plans of the stockholders call for the construction of a \$200,000 breaker on the tract, while work has already been undertaken on the building of a road leading up the mountain side.

The breaker construction will be started in the Spring. Officers of the company, in addition to Mr. Jordan, are: William Mack, vice-president; William Willis, treasurer; James T. Hanlon, secretary, and Albert Zenke, assistant treasurer. James J. Wilson, Joseph F. Moran and Richard Philbin are also among Scranton men interested in the project.

The Union Trust Co., of Pittsburgh, trustees of the Consolidated Connellsville Coke Co. first-mortgage 15-year 6-per cent sinking-fund coupon gold bonds, dated Dec. 1, 1910, has announced that at the request of the company it will pay and redeem on Dec. 1 all of the outstanding bonds, numbering 197, at par and accrued interest to that date, together with a premium of 5 per cent. Interest on the bonds will cease Dec. 1.

As a result of the ending of an agreement with B. Nicoll & Co., Inc., as sales agents the Pittsburgh Terminal Coal Co. will market its own product. The agreement, which had existed for many years, was terminated by mutual consent on Oct. 31. H. K. Stauffer, vice-president in charge of sales and formerly vice-president of B. Nicoll & Co., will look after sales for the Pittsburgh Terminal Coal Co. with offices at Pittsburgh.

The Fairbanks coke plant, consisting of 230 acres of land from which much of the coal has been removed, 200 ovens, 40 houses and plant equipment, has been sold by the receivers of the American Coke Corporation to George Santos, Jr., of Uniontown. The consideration was \$90,000. The plant, located at Fairbanks, in the Lower Connellsville district, was originally built and operated by the Struthers Furnace Co. It was taken over by the American Coke Corporation in 1920.

The tipple and boiler house of the Corrado Coal Co. at Fort Hill, which were only recently purchased, were destroyed by fire Nov. 5. It is believed the blaze had its origin in a spark from a passing locomotive.

Mayor Durkan, of Scranton, held a conference Nov. 1 with James B. Smith and J. Rossa McCormick, of the city's mine-cave bureau; A. W. Long, H. L. Harding and E. F. Blewitt, mining engineers, and discussed the advisability of increasing the valuation of coal lands in the city from \$320 to \$581 per foot-acre for taxation purposes during 1924. It is understood that the city officials are figuring on an average value of approximately 41c. per ton on coal in place, with the number of tons per foot acre placed at 1,400.

Philip Maue, for the last 15 years a mining engineer, has been appointed superintendent of Mt. Lookout colliery of the Temple Coal Co. at Exeter Borough. Since the retirement of Bruce Weir, in February last, the colliery has been without a superintendent. Mr. Maue will move from Shamokin to Wyoming. For the last four years he has been mining engineer for the Susquehanna Collieries Co.

W. H. Brights, of Elmira, N. Y.; M. H. Reap and Joseph A. Murphy, of Scranton, have obtained a lease on a coal dump at the Manville colliery of the Hudson Coal Co., near Carbondale. They also leased the Manville breaker and washery. It is estimated that there are over 90,000 tons of marketable coal in the dump and the new owners are organizing a company to market the product which they will obtain after washing the culm pile.

UTAH

Speaking at the Harvard Club, New York City, to the New York Section of the American Institute of Mining and Metallurgical Engineers, Nov. 7, J. V. W. Reynders said that byproduct coke ovens and blast furnaces soon would be operated at Provo, using coal from Carbon County, about 100 miles away, and iron ore from a point in Iron County about 200 miles distant, the point chosen for the furnace being favored because of the water available and the existing railroad routes. The blast furnaces will be ready in the spring. At present the pig iron will be shipped to the coast for further treatment. The aggregate assembly cost of material at Provo will be less than that to be met in the Pittsburgh or Chicago district.

WASHINGTON, D. C.

In compliance with a request from the Department of Commerce, the National Retail Coal Merchants' Association has designated its members of the committee which is to act in an advisory capacity on coal matters, as follows: S. B. Crowell, of the George E. Newton Coal Co., Philadelphia; M. E. Keig, of the Consumers' Coal Co., of Chicago and Roderick Stephens, of the Stephens Fuel Co., New York.

The Navy Department has awarded contracts for 25,000 tons of steaming coal for delivery into storage at the Naval Fuel Depot, Sewalls Point, Va., based upon the bids submitted on Nov. 1, as follows: W. H. Brown Coal Co., Inc., Norfolk, Va., 5,000 tons at \$4.42 per ton; Eastern Coal & Export Corp., Richmond, Va., 10,000 tons at \$4.75 per ton; and Fayette Smokeless Fuel Co., Mt. Hope, W. Va., 10,000 tons at \$4.87 per ton.

Bids will be received by the Bureau of Supplies and Accounts of the Navy Department, Washington, until noon, Nov. 21 for the transportation of coal from Hampton Roads by vessel to Portsmouth (N. H.) Navy Yard, Puget Sound Navy Yard and Pearl Harbor Naval Station. From 3,500 to 5,000 tons are to be carried to Portsmouth between Dec. 1, 1923, and Jan. 15, 1924; 6,500 to 8,000 tons to Puget Sound between Jan. 1 and May 15, 1924, and 6,500 to 9,000 tons to Pearl Harbor.

WEST VIRGINIA

Colonel C. W. Watson, of New York, president of the Consolidation Coal Co., headed a party of officials of that company who inspected the mines of the concern in Kentucky during the early part of November. Others in the party in addition to Colonel Watson were Sprigg D. Camden, vice president of the company; A. Brooks Fleming, assistant to the president; Dr. F. H. Birmingham; Miss Lucy Watson, a sister of Colonel Watson, and Graham Turnbull, private secretary to Colonel Watson.

According to estimates made by A. O. Wilson, statistician of the Kanawha Coal Operators' Association, there will be more coal produced in West Virginia during the present calendar year than during any previous year in the history of the industry in the state. Mr. Wilson estimates that the total production of the state will reach not less than 90,000,000 tons, or about one-fifth the total tonnage for the United States as a whole. Such a production will be reached notwithstanding the fact that in recent months there has been an extremely poor market for coal in West Virginia. The Chesapeake & Ohio loaded more coal during October than during any previous month in the history of the road. It is estimated that total loadings reached 78,000 cars, or about 3,900,000 tons.

The Westmoreland Coal Co., operating in the Irwin Basin of Westmoreland County, Pennsylvania, has taken title to the Laurel Coal Land Co.'s property of 5,518 acres on the waters of Spruce Fork and Little Coal River in Boone County, lately owned by the Chilton family, of Charleston. The consideration was in excess of \$600,000.

Five grievances in dispute between miners and operators were settled at a recent meeting of the joint board of the Northern West Virginia Operators Association and representatives of the United Mine Workers of America, held in Morgantown. All the cases involving disputes within the territory of the Northern West Virginia association are understood to have been settled without much difficulty.

Announcement has been made of the appointment of John Stewart as general mine manager of all the J. S. Sullivan mines in southern West Virginia. Mr. Stewart has had charge for some time of the J. C. Sullivan mines on the Norfolk & Western. His headquarters will be at Tralee, a central point for the mines which are located in Raleigh, Wyoming and McDowell Counties.

The large wooden tipple at the No. 1 mine of the Tidewater Coal & Coke Co., at Vivian, owned by the Houston interests, is a total loss as the result of a fire, the origin of which has not been established. The tipple was not being operated at the time of the fire, which started about an hour before the day's work began. It is thought that the wooden structure will be replaced with a modern steel tipple.

Plans are being laid by the West Virginia Department of Mines, co-operating with the West Virginia University, to increase the enrollment of students in the night school mining classes held throughout the coal fields to 1,200. R. M. Lambie, chief of the department, has announced. The enrollment now is between 800 and 900.

The Raleigh Coal & Coke Co., which is establishing a modern mining community at Raleigh Heights, in the Winding Gulf field between Raleigh and Sylvia, has awarded the contract for twelve dwelling houses, which will be built of red tile. It is planned to build 250 modern dwellings in all for miners.

The Gibraltar Coal Co. has just been launched by Charleston capitalists with a

view to operating in the Kanawha field. The company has a capital stock of \$100,000, and its principal office is to be at 110 Hole Street, Charleston. Having an active part in organizing this company were H. Steen, H. W. Bowers, I. F. Somerville, E. F. Huddleston and F. H. Withrow.

The Roberts & Schaefer Co. is erecting a steel tippie equipped with late model screens and loading booms at the Nellis mine of the American Rolling Mill Co.

CANADA

Canadian mines during August produced 1,585,000 net tons of coal, an increase of 60 per cent over the previous month and 27 per cent over the average for the same month of the three preceding years, according to the Dominion Bureau of Statistics. The output for the month showed increases of 489,000 tons in Nova Scotia, 98,000 tons in Alberta, 3,000 tons in British Columbia and 1,000 tons in Saskatchewan. The cumulative output from all mines for the eight months of 1923 amounted to 11,376,000 tons, an increase of 22 per cent over the preceding three-year average for the same period. Imports of coal during August totaled 2,746,000 tons, as compared with 2,445,000 tons in July. During August 36,900 tons of coal came from Great Britain. Importations of coal for the first eight months of the year amounted to 15,393,000 tons, an increase of 55 per cent over the preceding three-year average for the same period. Imports of anthracite in August amounted to 488,300 tons, which was 2 per cent less than in July and 40 per cent higher than the three-year average for the month. Of this tonnage, 468,700 tons came from the United States and 19,600 tons from Great Britain. The total amount of anthracite imported during the eight months ended Sept. 30 was 3,675,000 tons. Coal exported during August was 103,500 tons, as compared with 73,300 tons in the previous month. The cumulative exports for the eight months to date totaled 1,191,500 tons, or 17 per cent less than the three-year average for the same period. The tonnage of coal available for consumption in Canada during August was 4,227,000 tons, or 20 per cent more than in July, when 3,510,000 tons was made available. The total number of men employed in the coal mines of Canada during August was 28,670, of whom 21,516 worked underground and 7,154 on surface. The monthly production per man was fifty-five tons for August, as against thirty-six tons per man for July.

The collapse of the Home Bank of Canada hit the mining settlements in the Crow's Nest coal field, eastern British Columbia, pretty hard. The miners of Coal Creek are said to have suffered to the extent of \$200 per head on an average. The Crows Nest Pass Coal Co. used to keep its account in the Home Bank, but at the last general meeting of the company one of the directors of the Canadian Bank of Commerce became a director of the coal company, and the account shifted to that bank.

Silby Barrett, provisional president of District 26, United Mine Workers of America, has gone to Indianapolis to confer with John L. Lewis, International president, regarding a new wage contract for the miners of that district. While no announcement has been made when the conferences of the officials of the union and the Dominion Coal Co. with regard to wages will begin it is expected they will start soon after Mr. Barrett's return to Sydney.

Foundation Fuels Ltd., of Toronto, has been incorporated to deal in coal and other fuels with an authorized capital of \$20,000. The provisional directors include Frank X. Burrows, Hollis E. Beckett, and William N. Robertson.

Obituary

Reuben J. Humphries, 66 years old, coal operator and well-known resident of Scottsdale, Pa., died on Nov. 3. He had been in poor health for the past several years. Mr. Humphries resided in Scottsdale for a number of years. He operated a coal mine near Uniontown.

Jacob Rapp, one of the oldest coal dealers in Columbus, who retired from the active head of the J. Rapp Co. about 10 years ago, died at Columbus, Ohio, last week, at the age of 81 years. He had been in the coal business more than a half century.

Trade Literature

Tachometers. The Bristol Co., Waterbury, Conn. Bulletin No. 317. Pp. 31; 8x10 in.; illustrated. Describes recording and indicating models, both pneumatic and electric. Charts and list prices are included.

Cottrell Vibrating Screen. Southwestern Engineering Co., Los Angeles, Calif. Bulletin SC-1. Pp. 5; 7x10 in.; illustrated. Describes Cottrell screens, types A and B, the former being designed for either coarse or fine screening, both wet and dry, and the latter particularly adapted for coarse screening.

The Leahy No-Blind Screen. The Deister Concentrator Co., Fort Wayne, Ind. Bulletin No. 10. Four-page folder illustrating and describing the features, uses, operations and specifications of the Leahy No-Blind screen, suitable for screening either wet or dry materials from 2-in. opening to minus 80 mesh.

New Model Multiple Retort Underfeed Stoker. Westinghouse Electric & Mfg. Co., Stoker Dept., South Philadelphia, Pa. Catalog 1678. Pp. 14; 8x11 in.; illustrated. The distinguishing features of this stoker are its fuel-feeding mechanism, fuel burning and refuse disposal parts.

Erie Electrical Equipment Co., Inc. Johnstown, Pa., has issued a 53-page catalog on Fittings. The book is well illustrated and covers all types of fittings.

W. A. Jones Foundry & Machine Co., Chicago, Ill., has issued the following catalogs: No. 27, on Pulleys, covers cast-iron pulleys, ball-bearing loose pulleys and ring-oiling loose pulleys; also steel, wood and paper pulleys. No. L-28 contains data on Friction Clutches.

Seven Wonders of Wrought Pipe. National Tube Co., Pittsburgh, Pa. This booklet, 3x6 in., tells of instances where National pipe has come through accidents unscathed.

Publications Received

Engineering Features of the Moffat Tunnel; address by D. W. Brunton, chairman of the Board of Consulting Engineers to the Moffat Tunnel Commission, consulting mining engineer and former president, American Mining Congress. Delivered at a dinner of Colorado Scientific Society, Oct. 6, 1920. Describes topography and advantages of tunnel in shortening route from Denver to Salt Lake City, geologic considerations, method of construction of one railroad and of one water or pioneer tunnel, at proposed cost of \$5,250,000, also ventilation and sociologic provisions. 17 pp., 6 1/2 x 9 1/2 in., 3 ill., paper covers. Publishers, Colorado Scientific Society, Denver, Colo.

The Pennsylvania Department of Forests and Waters has announced the completion of a bulletin on "Volatile Matter in Pennsylvania Coals." It has been prepared by James D. Sisler, of the State Topographic and Geologic Survey. The bulletin contains a map showing the percentage of volatile matters of coals in the bituminous and anthracite fields. The discussions in the bulletin are based upon analyses of coal from 700 mines in Pennsylvania, made by the U. S. Bureau of Mines in co-operation with the State Geologic Survey. The bulletin presents for the first time the location of lines of equal volatile matter in Pennsylvania coals and shows graphically the relation of folding, faulting and movement to the chemical character of coals. It also shows the relation of oil and gas pools to volatile matter in Pennsylvania coals and points out the fact that great caution must be used in drilling in areas known to be much altered by folding and faulting.

Design of Concrete Structures, by L. C. Urquhart. Pp. 450; 6x9 in.; illustrated. Price, \$4. A textbook on concrete and reinforced concrete design. McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City.

Electrical Machinery Apparatus and Supplies. Census of Manufacturers, 1921. Bureau of the Census, Washington, D. C. Pp. 19; 6x9 in.; tables. This report is one of the series presenting the results of the first biennial census of manufactures, which covered the operations of manufacturing concerns during 1921.

The Merchants' Association of New York has issued its 1923 Year Book, comprising

394 pages. It contains alphabetical and classified lists of its members, index, plan of organization and reprint of its bylaws.

The Destruction and the Reconstruction of the Mines of Lens by E. C. Cuvelette, general manager of the Len mines; 9 x 11 1/2 in., pp. 20, paper cover; translation of "La Destruction et La Reconstitution des Mines de Lens"; Publisher, L. Danel, Lille, France.

Traffic News

Questions involved in fourth section applications in connection with rates on coal from points in Ohio to points on the Grand Trunk Ry. will be considered at an Interstate Commerce Commission hearing in Columbus, Dec. 10. Examiner Disque will preside. On the same date a hearing will be conducted in Cleveland by Examiner Satterfield in the case of the Cleveland & Western Coal Co. vs. the Director General of Railroads.

Rates applicable on coke, in carloads, from Indianapolis to Marshalltown, Iowa, are not unreasonable, the Interstate Commerce Commission has found in the case brought by Tuffly Brothers Pig Iron & Coke Co. In similar fashion the Commission upheld the rates on coke from Indianapolis to Omaha. In that case the rates have been attacked by the Citizens Gas Co.

Decision by the Interstate Commerce Commission relative to leasing of the Carolina, Clinchfield & Ohio R.R. to the Louisville & Nashville R.R. and Atlantic Coast Line R.R. is expected soon after Nov. 20, according to Edward S. Jouett, vice-president and general counsel of the Louisville & Nashville R.R.

The Louisville & Nashville R.R., recently announced that in October it handled 57,462 cars of coal, representing the largest month since May and June of 1922, when the general mine strike in union fields resulted in a great demand on Kentucky mines which favored with big demand and free car supply, operated at near capacity.

The Rocky Mountain & Santa Fe Ry. has applied to the Interstate Commerce Commission for authority to acquire the line of the Santa Fe, Raton & Eastern R.R. for the purpose of furnishing carrier service for the Sugarite and Yankee coal mines, in the Raton field of New Mexico.

Having been notified by the Interstate Commerce Commission that the appeal of the coal operators of southeastern Kansas for reduced freight rates from the fields near Pittsburg, to Kansas City, Mo., had been reported unfavorably by the commission's examiner, operators in Pittsburg are bringing up their resources to continue the fight.

Questions involved in the following coal traffic case will be considered at public hearing in Indianapolis, Dec. 4, before Examiner Carter: Citizens Coal & Supply Co. vs. Big Four; Hub Coal Co. vs. Wabash R.R.; Fourth section applications from points in the Clinton, Brazil and other coal-producing districts in Indiana.

The Baltimore & Ohio R.R. has placed orders for 500 all-steel hopper cars and 500 steel underframe box cars with the Pressed Steel Car Co., McKees Rocks, Pa., and the American Car & Foundry Co., Berwick, Pa., respectively.

Coming Meetings

Harlan County Coal Operators' Association, Nov. 21, Harlan, Ky. Secretary, E. R. Clayton, Harlan, Ky.

Illinois Mining Institute. Annual meeting Nov. 24, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

Second National Exposition of Power & Mechanical Engineering. Grand Central Palace, New York City, Dec. 3-8. Managers, C. F. Roth and F. W. Payne, Grand Central Palace, New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

West Virginia Coal Mining Institute. Annual meeting Dec. 4 and 5, 1923, Huntington, West Va. Secretary, R. E. Sherwood, Charleston, West Va.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 24

NEW YORK, NOVEMBER 22, 1923

Number 21

Waste in Antiquated Power Plants

IT SO happens that the peak demand for power at the mines coincides with the peak demand for coal and this has furnished the excuse for firing the larger, more valuable sizes of anthracite at mine power plants at such times. Antiquated power-plant equipment will not respond to overload demands unless fed with the cream of the coal. The practice is inexcusable, wasteful and expensive.

Doubtless a potent reason for the trend toward purchased power is found in the backwardness of the coal companies in modernizing their own power plants. Purchased power is cheaper than that generated by old methods, but there is nothing inherent in central-station practice that cannot be duplicated by coal companies. In fact many coal companies have large and efficient power plants comparable to the best of the central stations.

The best practice in the anthracite region now is to concentrate power production in modernized plants designed to utilize that part of their product which is least salable. The soft-coal fields with less incentive have made as much progress in this direction as the hard-coal regions.

A Stacked Deck

THAT the National Academy of Political Science should lend itself so obviously to a partisan exposition as that staged in Philadelphia last week adds nothing to the reputation of that organization as an open forum. The management of the two-day program on "The Price of Coal" was in the hands of Clyde King, Secretary of State for Pennsylvania, by appointment from Gifford Pinchot. In his contacts with the coal men Mr. King had already shown his colors and if a glance at the program of the Philadelphia meetings did but warn in advance, attendance confirmed the feeling that the deck was stacked.

Starting off with a talk by J. J. Walsh, Secretary of Mines, who defended the Pennsylvania State tax on anthracite and charged that 20 per cent of the anthracite now being shipped is below the normal standard of purity, the program veered to wages and earnings of the hard-coal miners. Whatever theory Mr. Drury may have had about the relativity of earnings of miners and other labor was obscured by his presentation, but John B. Andrews, secretary of the American Association of Labor Legislation, was clear in his exposition of "Needless Hazards in the Coal Industry." And so it went. Free discussion was practically eliminated by advance selection and by the lack of time afforded those who were on the program. Francis Walker read into the record the painful history of the anthracite combination, and J. W. Adams decorated the pages with the story of too many middlemen, all profiteers. Hugh Archbald gave a lugubrious picture of the inef-

iciency of the coal industry, sharply challenged, however, by those who followed.

It remained, however, for Governor Pinchot himself to divulge the real purpose of the symposium on "The Price of Coal." Defense, labored and statistical, of his 10-per cent increase to the miners and offhand characterization of anthracite as a "hard-boiled monopoly" summarizes his stock in trade. Such savage attacks, in which facts play small part and citation of gossip is in the forefront, ill becomes the stage of the National Academy of Political Science. It should be reserved for the political arena, where demagoguery is expected.

Would Compulsory Arbitration Work?

GEORGE OTIS SMITH does not hesitate to say in his address in New York this week, an abstract of which appears elsewhere in this issue, that the Coal Commission may have overlooked a bet in opposing compulsory arbitration of labor disputes. Harking back to the anthracite difficulties of last summer, he plainly says that "some of us" would rather have seen this dispute between the hard-coal operators and miners settled by compulsory arbitration than by political machinery. This is much plainer talking than any indulged by the Commission. But then the Commission is defunct and a fair target for all, even former commissioners. Incidentally Dr. Devine, in the November *Survey Graphic*, expresses huge satisfaction with the work, conclusions, and recommendations of the Commission.

There is an aspect to Dr. Smith's suggestion for compulsory arbitration that should not pass unnoticed. He says: "In the bituminous industry, however, compulsory arbitration of a wage-scale structure, to be fully successful as an agency of economic welfare, would need to have its awards enforceable throughout all coal fields, whether organized or unorganized." [Italics ours.] Now the common understanding of arbitration is the determination by a third party of a cause in controversy. Just how, then, could the wage rates of non-union mine workers be settled or adjusted by arbitration, since they are never in controversy, as between workers and employer?

Mr. Smith supplies the answer when he says "If coal mining, like transportation, is clothed with a public interest so great that its uninterrupted service requires public supervision of settlement of wage disputes [and he frankly holds to that belief] then those wage rates must be governed only by economic conditions, general and local, not by membership or non-membership in a union." Public welfare, he says, "must soon force such legislation as will insure an uninterrupted supply of coal."

If it be so that the only way the public may have a continuous supply of coal is to legislate against strikes and if when it does so legislate it must then bring the

present non-union fields under the cloak with John L. Lewis and the United Mine Workers of America, one will have nothing less than a National Coal Labor Board. Would the union swallow that as a price for getting the non-union fields in? Is it the price the non-union operator may have to pay for the doubtful advantage to him of strikes in the union fields?

We are not ready to concede the inevitableness of federal wage fixing in coal on a national or on any scale. We prefer to believe that the operators and the union are taking a broader view now than when they were cooking up the trouble that precipitated the 1922 disagreement. If for once the politician may keep hands off we look for a logical, non-contentious settlement next spring.

Hounding the Trade Association

THERE is no dodging the conclusion that the effort of Secretary Hoover to promote better business statistics and that of the Attorney General to hamstring trade-association activities represent fundamentally opposing theories. The Department of Justice has one, and apparently only one, test to be applied when the legality of any phase of trade-association activity is under fire. That is—Does this activity serve to enable the association members to profit? If it does; if it in any way benefits the participants, then it is enjoined.

We would not be thought of as criticising the endeavors of the Department of Justice to bring before the courts those who conspire to enhance prices under the guise of innocent co-operative action. We but point out that no trade association can persist—can obtain current financial support—that does not show some return on the investment in it. This is particularly true with respect to the function of business statistics.

A case in point is found in the draft of a proposed consent decree in the case of the U. S. vs. the Tile Manufacturers Credit Association. The Department of Justice here proposes to enjoin the association from collecting statistical information except such data as some government department should request, and even that information could not be distributed among the members of the association. This in effect would serve notice on all trade associations that the Department of Justice regards the collection of statistical and other trade information within the condemnation of the law and to be prohibited in so far as possible.

Carried to a conclusion such reasoning would prevent local coal associations from collecting the figures used by the Geological Survey in its weekly reports of mine operation and causes of lost time. It would cut off the sources of much of the essential production data published in the Survey of Current Business by the Department of Commerce. It would bring to an early death the growing body of business information that primarily is by and for the business man.

The Department of Justice appears obsessed with the purpose of making all co-operative business effort criminal. It would make light its work of judging the right from the wrong by prohibiting all. It will not give a single constructive interpretation to the law aimed to permit or encourage trade associations perhaps until it has carried to a conclusion all its pending actions. It does not add to the credit of the department that it thus tenaciously holds to the literal law any more than it is to the credit of some trade associations that they have actually abused, yes seriously abused, the association idea.

The Passing of the Siphon

NEED for continual nursing has made the siphon unpopular. For this reason the use of it is rapidly declining; so much so that it comes rather as a surprise that such an instrumentality is discussed by a subcommittee of the Standardization Division of the American Mining Congress. Much of the objection to the siphon might be eliminated if some of the facts of its operation were understood. One that few consider is that the water in the lower end of the suction leg during filling is under the combined pressure of the atmosphere and of the water column say 23 lb. and that after the water begins to move that pressure is reduced to about 5 lb., or about one-fifth as much. The pressure in the discharge leg is even more before the column starts. Consequently every bubble large and small trapped in a pipe joint or resting in some slight elevation in the pipe becomes magnified five or more fold and expands. In both ends these bubbles become disengaged by the suction and tend to rise to the summit, and if they are not washed out by the rapid flow of the water will block the pipe.

Unless the water flows fast enough to drive these bubbles out the siphon will soon stop. Hence unless a siphon expels air it is not likely to continue to run long. To aid in dislodging the air a few sharp raps on the various lengths of pipe forming the siphon during the filling process will help the air to rise to the high point and escape, provided, of course, the siphon is being filled at the summit. If there are elevations along the line the pipe can be tapped at these points and plugged with tight pine plugs removable during the filling process, the method being to remove them all and replace them as fast as the line fills. In fact one man of experience would arrange for small elevations at which bubbles can be removed in the filling process, leaving the pipe reasonably free of air. The pipe at each of these elevations is tapped with a small hole and a plug inserted.

More air, however, is brought with every gallon of water admitted. Consequently these elevations might be undesirable. All the water brought to the siphon is relieved of about one-third of its pressure, and the natural effect is that air is disengaged as bubbles. This air, not being absorbed by the water, must be expelled by it in a segregated form and a siphon is not working well unless it is voiding air at the lower end.

The siphon has another disadvantage in that it cannot be allowed to run dry. Therefore it must never complete the work it has on hand. Sometimes to prevent its completing the drainage of the sump it is throttled down, but the effect of the throttling is to make it retain air in its system. In consequence it soon ceases to run.

The object of most endeavors being to perform the desired end promptly and not to achieve the object sought in part or in a long time the siphon is unsatisfactory in draining working places, apart altogether from its demands on labor and supervision. Where the water has to be voided from a working place the siphon must be made either dilatory in action or must be started and stopped frequently, unless, as suggested by the subcommittee on "Unwatering abandoned workings" of the committee on Mine Drainage of the Standardization Division of the American Mining Congress, several points of suction are provided which are used in turn and closed when the water in them is lowered to the suction level.

No. 14 Colliery, Pennsylvania Coal Co.

Advance in Steam-Boiler Practice in Anthracite Region

Importance of Burning Small Sizes of Coal at Mines—Changes in Boiler and Furnace Design to Obtain Efficient Combustion—Benefits of High Stacks—Economizers Obviate Need for Increased Boiler Capacity

BY M. M. PRICE
The Babcock & Wilcox Co.

THE increasing value of anthracite gives added interest and importance to the work which has been done and still remains to be done by the engineers of the anthracite mining companies in their efforts to produce steam more efficiently. The advantages to be gained as a result of the changes which are going on are sure to accrue both to the coal companies and the consumers.

It is only under the stress of economic conditions that the anthracite mining companies have a sufficiently large market to absorb the great quantities of buckwheat, rice and barley—frequently called buckwheat Nos. 1, 2 and 3 respectively. By adopting the best methods of burning these small sizes in their own power plants the coal companies at the same time create their own market for small sizes and release large volumes of the salable sizes of coal for outside markets and consequently for domestic consumption.

Progress in mine power-plant design has been well marked for the past thirty years, not alone in changes in boiler design in keeping with the general development of that art and in solving problems of boiler design peculiar to this kind of fuel but also in the design of furnaces for proper combustion of the fuel.

The necessity for a small ratio of heating surface to grate surface influenced the change to water-tube boilers. At first this ratio was obtained by installing boilers of small heating surface of 150 hp. rating under which it was easy to install grates as large as required without resorting to those of excessive depth. As the size of the boilers was increased the maximum depth of the grate was fixed at 7 ft. and the boilers so designed that the heating surface per foot of furnace width was kept small. This was accomplished in boilers of the bent-tube type by using a small number of short tubes per section and in the straight-tube type by using sections not over nine tubes high.

The use of larger boiler units was brought about by the design of furnaces with grates 10 to 12 ft. deep, and in the case of the Babcock & Wilcox boiler led to the use of the "Webster" furnace. This provided for the deeper grates by moving the bridge wall toward the rear of the boiler the required distance, but maintained the front baffles in their original position and closed the space from the bottom of this baffle to the bridge wall by a baffle on the lower tubes.

The development of the deep grate made possible the use of units of approximately 500-hp. rating in which the ratio of heating surface to grate surface does not exceed thirty-five to one and in which the furnace width does not exceed 15 ft. This is the limiting size of hand fire units unless the width is increased or units used which are fired from both ends. The use of larger units of moderate widths, has, however, been made possible by the installation of forced blast chain-grate stokers, which marks the latest stage of accepted design in this field to date.

Exhaustive experiments undertaken in using anthracite fuel in pulverized form have been carried to such a stage as to warrant the statement that burning anthracite in this form will be the next step in the advance from present methods. The greatest difficulty seems to be in the crushing of the fuel rather than in its combustion. This has led to the consideration of a better preparation of the fuel before powdering by removing much of the abrasive ash before it goes to the pulverizers. This in turn has led to the suggestion that such preparation be given to coal that is to be burned without being pulverized. In view of the loss occasioned by the quantity of carbon in the ash and the high amount of ash when the coal is either hand or stoker fired, it would seem that the adoption of such a practice would produce real results in economy and capacity in both hand-fired and stoker-fired furnaces.

An inspection and study of the proximate analyses of samples of small sizes of anthracite give us an indication of one of the difficulties met with in using this kind of coal on hand-fired grates. Table I gives actual results of proximate analyses of a number of samples gathered from hand-fired plants at the mines.

It will be noted that the ash averages 20 per cent or over and with a combustion rate of 25 lb. per hour per square foot of grates, 5 lb. of ash per square foot of grate accumulates per hour. Such a quantity of ash means cleaning fires on hand-fired furnaces every three to four hours with the loss in efficiency due to the cold air entering the furnaces and high loss of unburned carbon in the ash. The importance of the last-named loss is indicated by Table II, which shows data taken from a number of observations at hand-fired plants giving the percentage of boiler ratings, the rate of combustion, the consequent percentage of carbon in the ash and the percentage of loss resulting therefrom.

The analyses and sizes of coal used when these data were observed are those given in Table I for the corresponding numbers.

The data quoted in Table II indicate that the loss due to carbon in the ash is the most serious one encountered in burning this kind of fuel, but much heat is lost in the flue gas; in fact the loss is larger than when burning other kinds of coal. This is due in part to three things: first, the excess air necessary to effect combustion; second, the difficulty in obtaining the mixture of the excess air with the gas distilled from the coal and, third, the slowness with which combustion takes place under the best conditions.

The small units of straight-tube boilers first installed were set with a distance of 5 ft. from the boiler room floor to the bottom of the front headers, and it was not until grates of a depth greater than 7 ft. were installed that this height was increased so as to increase the distance from the lowest tube to the grate surface at the bridge wall. In boilers of the bent-tube type with arches over the furnaces, an effort has always been made to cover as much as possible of the grate surface with the arches.

As the depth of the grate was increased, in order to provide sufficient clearance from the ends of the arches to the front bank of the tubes, where the length of the arches was extended to cover the grates, the boilers were raised and the arches lowered. This latter construction resulted in long shallow furnaces of small volume, with the fuel body cut off by the arch from any direct radiation to the front bank of tubes. This feature has been gradually changed by raising the boilers and shortening the arches so that they could be raised to a greater height above the grate, thus giving more volume in the primary furnace and exposing more of the front bank of tubes to the radiation from the fuel bed.

TABLE I—PROXIMATE ANALYSES OF SAMPLES OF FUEL USED AT HAND-FIRED MINE PLANTS

Sample No.	Per Cent Moisture	Per Cent Volatile	Per Cent Fixed Carbon	Per Cent Ash	B.t.u. per Lb. Dry	Per Cent of Various Sizes of Buckwheat

	152	21.62	42.52	22.88

The furnace construction used in the bent-tube boiler was perhaps responsible for the idea entertained by many, that no furnace could successfully burn the small sizes of anthracite unless its entire surface was covered by an arch. This idea led to the installation of a number of boilers of the straight-tube type with extension furnaces or with deep grates partly covered by arches underneath the tubes. Such construction made it necessary to set the boilers 10 ft. or more from the floor to the bottom of the headers, with a resulting increase in the furnace volume. The furnaces operated successfully, but as the arches gave out they were never replaced. The boilers were reset with the grates directly under the heating surface and operated with apparently the same or greater capacity and efficiency when burning even the small sizes.

Another cause of loss in burning the small sizes is that found in the "unaccounted for" item of a careful heat balance, a large part of which is unconsumed carbon blown out of the furnace by the draft. This loss when burning a fuel made up of 4 per cent, No. 1; 14 per cent, No. 2; 74 per cent, No. 3; 8 per cent under No. 3 buckwheat, amounted to 4.11 per cent when the boiler was operated at 93 per cent of rating and 6.63 per cent when the boiler was operated at 130 per cent of rating.

No direct measure of the loss due to unconsumed carbon in the flue dust was made in the observations which were available to me, but by assuming a definite loss for radiation and heat in the ash, the balance of the "unaccounted for" may be safely assumed as representing the loss due to the unconsumed coal. The changes in furnace design described above, leading to not only a greater furnace volume but to a construction in which the velocity of gas is low, probably do much to cut down loss from this cause.

Coincident with the development in boilers has been the improvement in the arrangement and proportions of the drafting apparatus. Note has been made already of the low rate of combustion possible with the small sizes on account of the large percentage of ash present and the difficulty of forcing sufficient air for combustion through the fuel bed. The air pressure necessary for the combustion of various sizes at different rates is given in Table III.

It will be noted from this table that a pressure equivalent to nearly 2 in. of water is required to burn 25 lb. of No. 3 buckwheat per square foot of grate surface per hour, which is equivalent to approximately 150 per cent of rating for a boiler with a ratio of heating surface to grate surface of thirty to one. If the boiler is of the straight-tube type with a bank nine

TABLE III—AIR PRESSURE RECOMMENDED AT VARIOUS RATES OF COMBUSTION

Rate of combustion, lb. per sq.ft. grate area	Air pressure required for No. 1 buckwheat	Air pressure required for No. 3 buckwheat
10	0.25	0.40
15	0.45	0.75
20	0.68	1.25
25	1.00	1.90

tubes high, the draft loss would be equivalent to not quite one half inch of water and a stack 110 ft. high would be required to overcome this resistance.

The earlier plants were equipped with stacks of a height seldom exceeding 50 ft. while in nearly every plant the boilers were equipped with apparatus for developing a plenum draft either by means of a steam blower or fan. Such an arrangement gave an insufficient stack draft, which resulted in a plus pressure in the furnace with a consequent deterioration of brick-work, arches and baffles, and loss in efficiency due to such deterioration.

The Lehigh Valley Coal Co. was one of the first companies to correct this draft condition in a plant which was erected at Hazleton Shaft. In this plant, built about 1897, both plenum and vacuum fans were installed to supply pressure under the grates and pass the gases through the boilers. The installation was the first in which this combination was used.

For a long time no one attempted to do away with the vacuum fans by building high stacks. This was partly due to the nature of the ground on which most colliery power plants were built. However, in 1911, the engineers of the Pennsylvania Coal Co. with great courage and enterprise built a stack 175 ft. high in connection with their plant at Underwood, and later built two stacks of the same height at their No. 14 colliery.

The difficulty of obtaining a fair rate of combustion and therefore a high rate of evaporation from the boilers together with the lack of sufficient stack draft has led in many instances to ill-advised changes in baffles to obtain larger gas passages and the resultant lowering of draft resistance. Or, if these changes have not been deliberately made, the lack of draft sufficient to meet the demands for steam has been responsible for failure to maintain this important part of the boiler.

Very often no attempt is made to maintain a balanced draft, and in order to generate the steam required under the condition imposed by the lack of stack or induced draft, a pressure is used under the grate sufficient to create a plus pressure in the furnace with ensuing deterioration of the walls and arches.

The loss due to unconsumed carbon in the ash at hand-fired plants is attributable to the manner in which the fires are cleaned and could be cut down by saving all the live coal in the cleaning by pushing it back or to one side. In almost all hand-fired plants, however, the process of cleaning consists in either dumping or pulling a large part of the fires and leaving very little of the old fire bed for kindling the new. There is nothing that can be done in the construction of the furnaces which will cut down this loss; it can be controlled only by better operation.

A development in the design of the traveling chain grate has been the placing of an arch over the rear of the stoker surface so that the gases which have passed through the rear part of the grate pass over the surface of the fuel bed in a direction opposite to that of the travel of the grate and throw any particles of

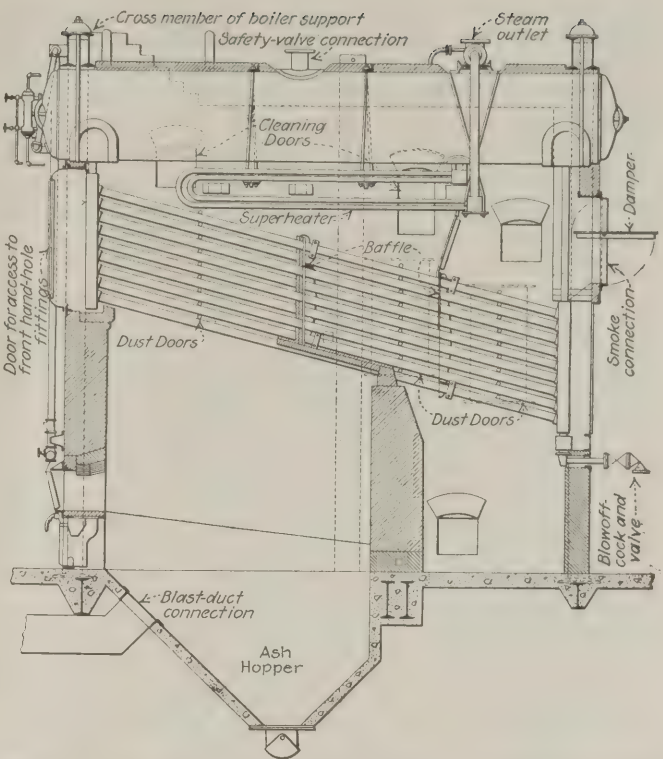

FIG. 1—STRAIGHT-TUBE BOILER WITH DUMPING GRATES FOR BURNING SMALL SIZES OF ANTHRACITE

The baffle on the lowest row of tubes helps to provide the desired ratio between grate surface and heating surface. This arrangement of the ash hopper is desirable for all grates having a depth in excess of 8 ft.

incandescent carbon which have been lifted from the grate by the blast toward the front of the grate. This construction has been remarkably successful, yet its control is still largely dependent upon the operator.

Another difficulty is presented in the removal from the fire bed and the disposal of the large quantity of ash resulting from the combustion of the small sizes of anthracite. Passageways are installed under the fire-room floor for handling it, and in the use of grates of a depth exceeding 7 ft. this construction is imperative as the difficulty of scraping the ashes from a pit of this depth is as great as, if not greater than, cleaning a fire on a stationary grate of a corresponding depth.

Several ingenious ways of handling the ashes by flushing have been devised. In some of these the ashes are flushed directly into abandoned workings in the mines for surface support, but in others, notably at the Nanticoke and Hampton plants of the Glen Alden Coal Co., where this opportunity does not exist, the ashes are flushed into wells from which they are removed by clamshell bucket and crane.

As already noted, the principal source of loss in burning small sizes of anthracite is in the large percentage of carbon in the ash. No changes in the design of the hand-fired boiler itself suggest themselves to remedy this, but it is apparent from an examination of Table II that great economies may be accomplished by cutting down the rating at which it is necessary to operate the boilers.

In a boiler plant burning bituminous coal the principal loss is the heat in the flue gases. In the boiler plants under consideration burning anthracite this loss is large also, although equalled or surpassed by that due to the carbon in the ash. Of a number of representative analyses of flue gases at these plants the best average analysis showed 10.12 per cent CO₂, which is

equivalent to 80 per cent excess air over the theoretical amount required for combustion, or 14.63 lb. of gas per pound of coal burned. With a stack temperature of 524 deg. F. the heat loss represented 14 per cent of that of the coal. This analysis was obtained with an average combustion rate of approximately 25 lb. of coal per hour per square foot of grate with the boiler operating at 148 per cent of its rating, which was 463 hp. The fuel fired contained 83 per cent of No. 3 buckwheat and smaller.

A higher rate of combustion often is maintained in hand-fired plants, but it is difficult to do so and keep the CO_2 even up to the figure noted above. At these higher rates a delayed combustion occurs, which results in high stack temperatures and trouble with dampers, baffles, etc. Increasing the volume of the furnace has overcome this difficulty to some extent, but there is room for investigation along those lines, and it still remains for some courageous person to omit entirely the arches from a hand-fired boiler of the bent-tube type.

The loss and trouble from delayed combustion is accentuated in the stoker-fired boiler both by a more uneven distribution of air and a demand for higher ratings from this type of apparatus. The reverse-arch construction already referred to helps to overcome this difficulty by causing the gas to move in opposite

direction from the two ends of the furnace and mix at the outlet. Later types of construction of straight-tube boilers with stokers have been built with furnaces 15 ft. and 20 ft. high and boilers of the bent-tube type have been installed with several arches to further the mixing of the gas. These plants are just being put into service and while in consequence there is no authentic data as to their performance, they should reward the designers and builders with both capacities and efficiencies higher than those of boilers with lower and less elaborate settings.

Reducing the rate of combustion will not only cut down the ashpit losses as noted, but will help to keep down the loss in the chimney gases. An increased rating means a thicker fuel bed and an increased air pressure under the grates, not only to supply the additional air required for the combustion of the larger amount of coal but to provide sufficient force to drive the air through the thicker fuel bed.

We have seen from the foregoing that the ashpit losses and the chimney losses increase at extravagant rates and that the efficiency decreases as the rate of combustion increases beyond a limited amount of coal per square foot of grate in furnaces equipped with either hand-fired grates or stokers. In plants of this character, however, there is a very large demand for

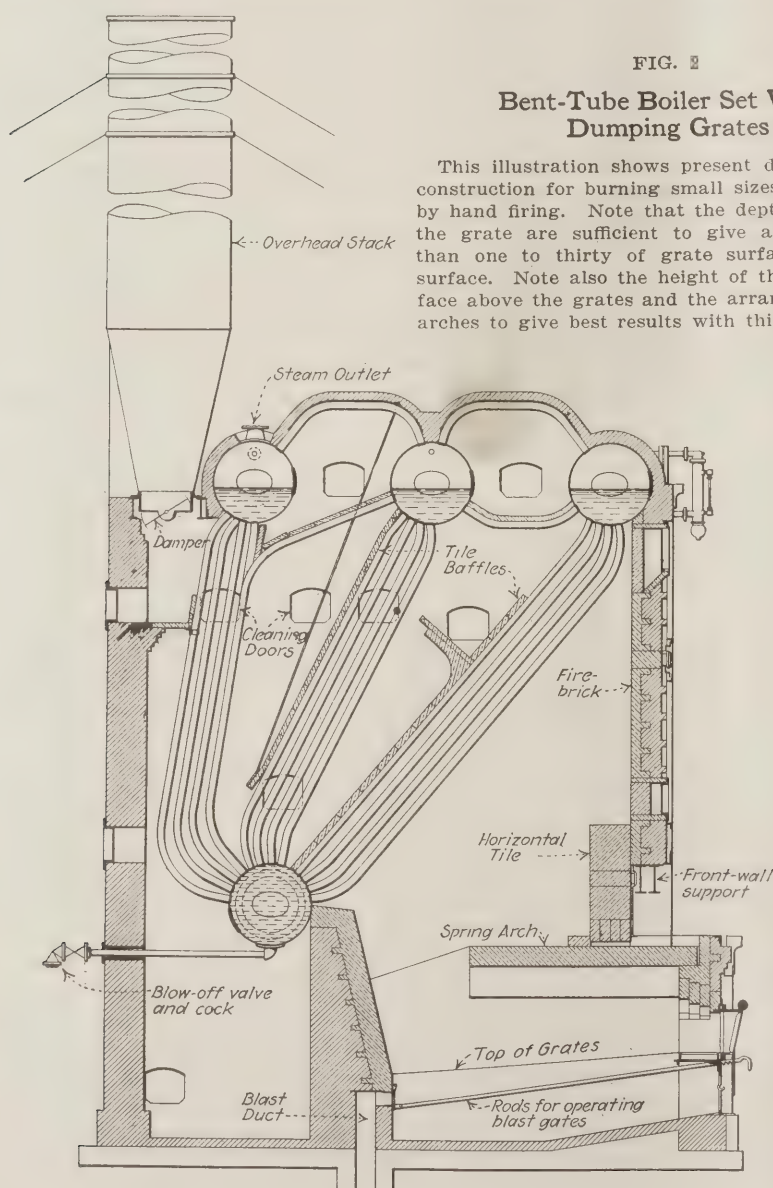

FIG. 2

Bent-Tube Boiler Set With Dumping Grates

This illustration shows present day practice of construction for burning small sizes of anthracite by hand firing. Note that the depth and area of the grate are sufficient to give a ratio of less than one to thirty of grate surface to heating surface. Note also the height of the heating surface above the grates and the arrangement of the arches to give best results with this fuel.

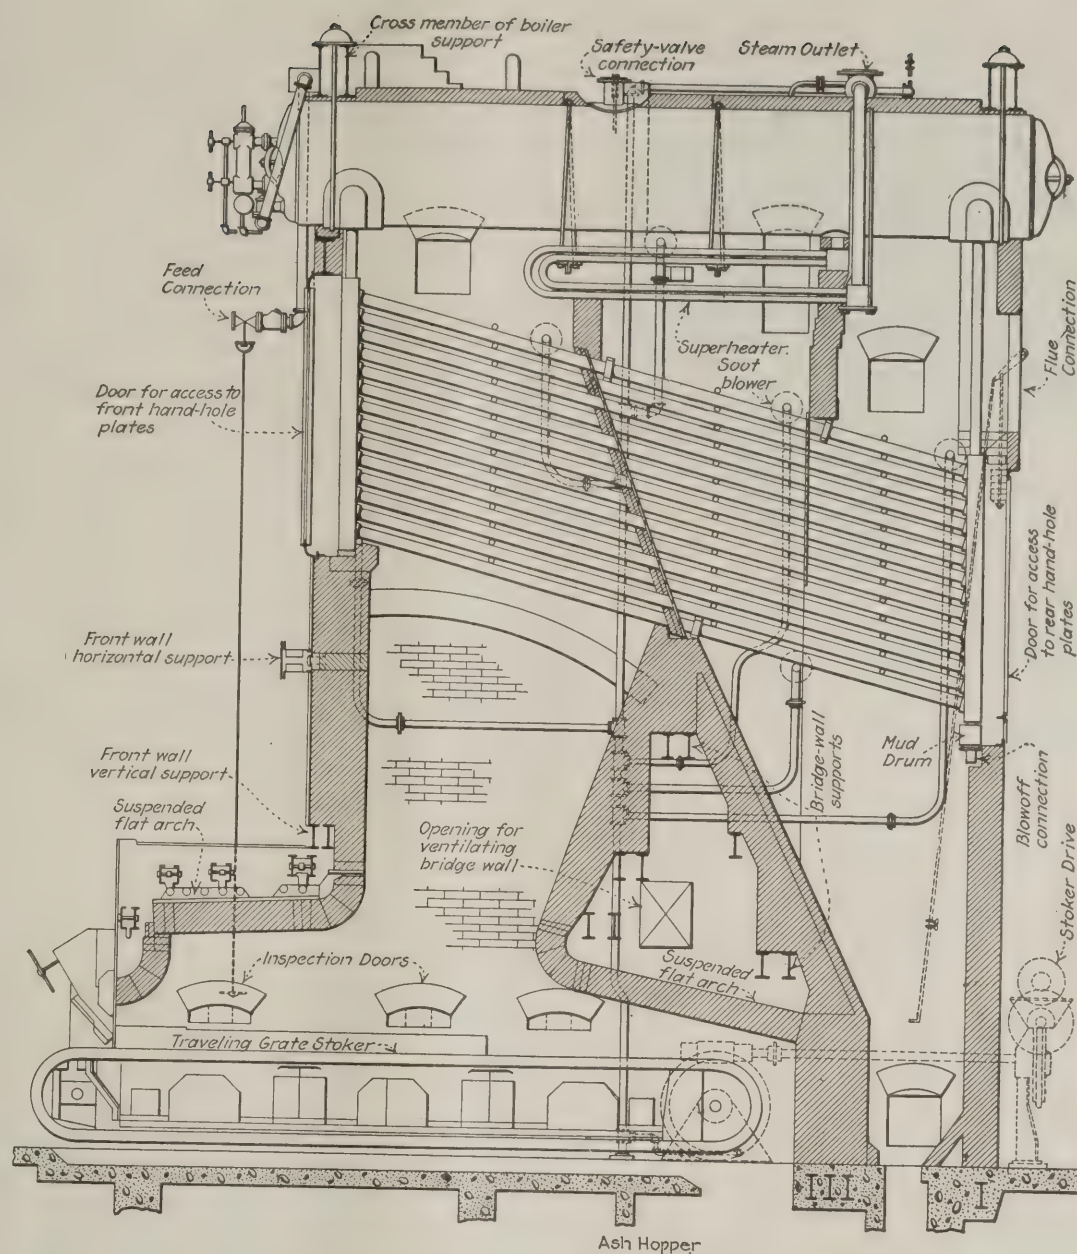

FIG. 3
Chain-
Grate Stoker
Under Straight-
Tube Boiler

This drawing shows how the boiler is set high above the floor to give a large combustion space and ample opportunity for the thorough mixing of the gases before they reach the heating surface. The construction of the bridge wall and flat arch over the rear end of the stoker causes the gases to move over the fire so as to get a better mixture of the suspended carbon and air.

steam and the problem seems to resolve itself into that of obtaining a greater capacity for a rate of combustion which is economical. Apparently we have reached the limit in the size of grate which can be installed per foot of furnace width; therefore to increase the efficiency we must—outside of giving the coal better preparation—increase the steam-generating capacity per square foot of grate by installing economizers or more and better feed-water heaters, or by installing more grate surface, which means installing more boilers.

Economizers have been installed in several colliery power houses, but at the time of their installation probably little thought was given to the increased steaming capacity of the plant which would result from the use of this equipment, or to the fact that this increased capacity would permit the operators to run with lower and therefore more efficient rates of combustion. The argument for economizers is generally the other way, viz.: that economizers permit higher ratings by cutting down the high chimney-gas losses consequent thereto, but in the plants burning small sizes of anthracite the ashpit loss is as great or greater than the chimney loss and increases with, and out of all proportion to, the rate of combustion.

Therefore the measure of gain from the installation of such equipment in these plants lies not alone in the amount of heat absorbed from the flue gases but also in the increased economy of combustion due to the lower rate demanded when the economizers are in use. The development of individual economizers for each boiler is thus justified, and besides this they require little additional boiler room space. The effect of economizers upon the capacity of a plant is readily seen from a study of the following concrete cases.

It is proposed to install a boiler plant which will evaporate 117,000 lb. of water with a feed temperature of 150 deg. F. into steam at 275 lb. pressure and 150 deg. superheat, which is equivalent to the evaporation of 137,726 lb. from and at 212 deg. F. for 4,000 b.hp.

If five 668-hp. boilers are installed with traveling stokers having a grate surface each of approximately 12 ft. x 17 ft. without economizers, this amount of steam may be generated by operating four of these boilers at 150 per cent rating, allowing one boiler to be always out of service for cleaning and repairs. If these boilers were equipped with economizers to raise the feed temperature 100 deg. F. the heat added to the feed water would be equivalent to the evaporation of

12,050 lb. from and at 212 deg. F., which would make possible the generation of the total steam required by operating the four boilers at 136 per cent rating.

Although the effect of heating the feed water in reducing the work required of the boilers and grates is considerable, and should be obtained in all plants of any magnitude, this effect is easily lost unless a sufficient number of boiler units are installed so that it will be possible to operate with a combustion rate not to exceed 25 lb. of coal per square foot of grate per hour, even when some of the boilers are off the line for cleaning and repairs. With a ratio of heating surface to grate surface of thirty-five to one, a coal with a heat value of 11,000 B.t.u. and a boiler efficiency of 60 per cent, this means a steaming rate of 140 per cent of rated capacity. A reduction in the ratio of heating surface to grate surface, assuming the same coal and efficiency, would bring this rating up to 160 per cent.

To persons accustomed only to the use of high-volatile fuels high in heating value and low in ash such limitation in rating may seem extravagant, but boiler plants designed on such liberal lines are a necessity at the anthracite mines, not only to permit the use of low-grade fuels but also to provide a plant which will generate the steam required and allow the removal of each unit from the line for cleaning and repairs at proper intervals.

We have come a long way from the practice which

prevailed with the use of the cylinder boiler, but there is still a lack of appreciation of the sensible limit of overcapacity possible with the use of small anthracite. And conversely, on account of this same limit in capacity, there is no other class of boiler plants which will show such fine returns for liberal design and proper upkeep.

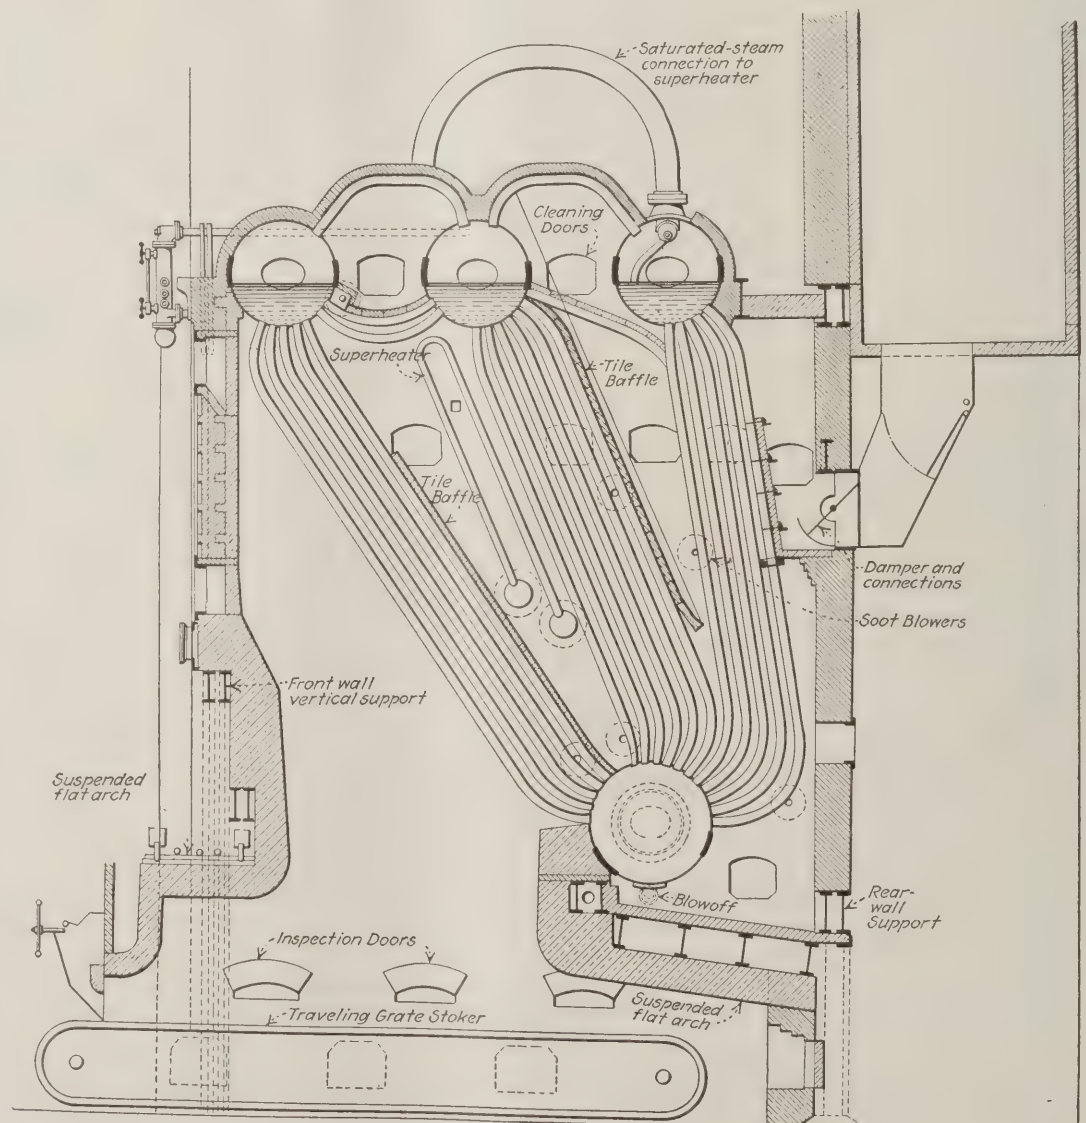

Every factor entering into the efficiency of the plant must be taken into consideration in order to make the use of the unmarketable sizes economical. This fuel may have no value before it is delivered to the boiler house, but handling and freight charges may readily bring its cost delivered to the boiler room up to 75c. to \$1 per ton. The low efficiency with which, of necessity, it must be burned calls for the consumption of greater amounts of fuel, the handling of more ash and the use of more labor than would be required with the use of larger sizes and better coal, so that it is difficult to determine just what proportion of the larger sizes may be mixed with it economically.

The same limitations as to rate of combustion and boiler rating, however, apply in the use of the better grades as apply in the use of the unmarketable sizes, but in the one case it improves the combustion of a fuel which can be sold, and in the other case makes possible the combustion of a fuel which is unmarketable and sets free for market a corresponding amount of the marketable coal.

FIG. 4

Automatic Stoker Under Bent-Tube Boiler

Note the large amount of heating surface exposed to radiation from the fuel bed, the height of the mud drum above the floor and the arrangement of the suspended arch at the rear end of the stoker for the better mixture of the gases.

Wasted Time at Partings Adds to Cost of Operation*

Evidence That Even in the Best Mines Cars Are Lacking at Partings to Keep Haulage Force Busy—Time and Size of Locomotive Trips Unequal and Uncertain—Haulage Units not Definitely Controlled

THE basic policies of production management in our industrial plants have been gradually undergoing a fundamental change during the last ten years—a change from the military type of control, where a superintendent or foreman is assumed to be omniscient in every branch of the operation—general supervision, maintenance of quality, inspection, the obtaining of large output, distribution of work and materials to men and machines, care of equipment, operation of machines, and repairs. From this the industry has advanced to the functional type of management, in which every supervisor is a specialist in his

foreman, the extent and diversity of the underground operations have been presented. The remark was made that the solution of the difficulty lies not necessarily in an increase in the number of foremen of the present type but in the development of management methods that will give specific attention to certain kinds of inefficiency.

Our examination of mining operations pointed out to us how necessary it is that underground management should follow the trend that has proved so effective in producing economies in those industries which operate above ground. In some directions this trend already has been exemplified at coal-mining plants. At several bituminous mines, for example, we find that stores are controlled with running inventories and a systematic plan has been devised for the issuing of supplies which is in every way as effectual as those of many of our best industrial plants.

We believe the cost-accounting and payroll records in coal mining are more systematic and uniform than in any other industry in the country. We question whether the plants, large and small, in any other business than mining would have had on file the unit cost and payroll data which enabled coal operators without difficulty to fill out certain of the Commission's questionnaires.

But mining-engineering problems in general are not well handled. A few mines are developing statistical information of incidental value in management. Underground, however, the methods of controlling the operations, except in a few instances, are scarcely different from what they were fifty years ago.

MINE FOREMAN MUST BE AIDED BY SPECIALISTS

The mine foreman with his long experience in mining must continue to function, but his efforts and his knowledge of mining must be supplemented by the aid and information supplied by specialists who are experienced in applying, to problems of management, engineering analysis and planning, for it is a physical impossibility for him to devote sufficient time to make these analyses. It is readily apparent that they are needed, and in no place is this more evident than in the control of underground haulage.

Irregularity of Haulage of Mine Cars.—Underground haulage is the circulation system of the mine. Upon the proper delivery of pit or mine cars to the miner

FIG. 1—NUMBER OF LOADED CARS ON PARTING AT ANY GIVEN TIME IN MORNING.

Where no black blocks rest on the base line, as is the case, for instance, in that part of the record for the period shortly after 8 a.m., a locomotive arriving would find no cars to take out. At other times it would find, it will be seen, an insufficient number for a full trip. It would have been helpful if the time when locomotives arrived and pulled out had been indicated in the diagram. In every case, whether the loaded track was full or empty, it was completely cleared by the locomotives, which apparently took trips of quite varying length.

particular line. Notably, the planning of the work and the determining and maintenance of standards have been separated from those duties that are strictly executive in character.

In the previous discussion of the work of the mine

*Third installment of report on "Underground Management in Bituminous Mines" made by Stanford E. Thompson and associates to the U. S. Coal Commission. Previous installments may be found in the issue of Nov. 8, p. 691, and of Nov. 15, p. 733. Other sections of this interesting report will follow later.

FIG. 2—NUMBER OF EMPTY CARS ON PARTING AT ANY GIVEN TIME IN MORNING

Where no black block appears resting on the base line the empty track was indeed empty, being empty of empties. At such times, trips of loads would come in, and the hauling equipment would have no empty cars to take back. Looking at the "sky line" it is easy to see that the main-line locomotives hauled trips of mine cars of varying length, that at 9:30 a.m. being unduly short.

depends his ability to do a good day's work. Moreover, the supply of coal to the tippie for shipment also is dependent upon the haulage.

Though the general schemes of transportation and trackage are fairly well planned, in the actual operation of the mine the whole control of transportation is almost universally in the hands of the assistant foreman or face boss or still oftener is handled at the will of the man driving a mule or a gathering locomotive. In one or two cases, however, we found a traffic man provided, to whom the motorman reported by telephone so that the trips might be taken up when ready, but even this did not directly reach or influence the delivery of cars to the miners.

The resultant irregularity in the distribution of mine cars is responsible for the agreement with the union that each loader shall have an equal or "square turn," which requires, in effect, that during each pay period every loader shall be given an opportunity to load as many cars as any other loader by being offered the same number of empty mine cars. This is intended to prevent favoritism and the possibility of one miner being required to spend the greater part of his day waiting for cars while another miner in a location where the management is anxious to push production would be given all the cars he could load.

MOVEMENT OF TERMINALS HAMPERS PLANNING

In non-union mines, in order to avoid complaints, keep the men contented, and produce as much coal as practicable, the foremen, so far as we are able to determine by conversation with the miners, treated them as equally as management methods permitted without the tendencies to restriction found in some union mines of keeping back cars from the exceptional men who desired to make large money.

The problem of underground haulage is a transportation problem complicated by the fact that all the terminals except the track to the tippie are continually advancing, and the number and location of the advance terminals change from day to day. The cumulative

advance of all inside terminals in a large mine may easily total 1,000 ft. daily, though each terminal will advance only a few feet.

Compared to the problems of transportation of the modern railroad or army those of the coal mine are relatively simple. They are in no way complicated by continual changes in the types and quantities of goods to be hauled, by perishable articles, blizzards, crop-moving seasons, or greatly varying velocities of travel.

Coal-mine transportation, however, falls heir to all the other troubles of the modern railroads, to which are added many special difficulties peculiar to mining. It is complicated by roof falls, explosive gas, multiplicity of terminals—400 or 500 being not uncommon—but is simplified by the fact that its freight is of only one type and is carried relatively short distances, four miles ordinarily being the maximum distance. Sufficient progress has been made in some mines to warrant a general assertion that mine haulage is susceptible to close control under proper management and that most of the losses now occurring can be eliminated.

Whether the problem is simple or not, as compared with that of the movement of material in other industries, underground haulage cannot be expected to run itself and this is practically the way in which the transportation in the majority of mines visited was

FIG. 3—ONLY AT THE BEGINNING OF THE DAY WERE THE MAIN-LINE LOCOMOTIVES REALLY BUSY

The morning started with 97 cars accumulated on the previous day, when the tippie and main-haulage system were idle. Note the irregularity in arrival of the main-haulage locomotives and the variation in the size of trips hauled. The two figures in the base line of the diagram, 11:00 and 11:30, show the noon half-hour during which loaded cars evidently arrived but did not leave the parting.

FIG. 4—RECORD OF FIG. 3 SEEN FROM OTHER SIDE

All the cars at the parting being full at starting time, the main-line locomotives were busy, but the seven gathering locomotives were idle for forty-five minutes. The day started splendidly at the tippie, but the scene was quite other at the parting. After 8.15 a.m. the faults were corrected and at all times thereafter empties were standing on the track.

being performed, notwithstanding the fact that these mines were among the best in the various regions studied. Generally the foreman is not equipped by training to handle transportation systematically. Even when he has the training it is of but little use, for he cannot spare sufficient time from his other duties properly to direct haulage.

Illustrations of Haulage Irregularities.—The efficiency of haulage is so great a factor, both to the miner in determining his day's work and money earned and to the operator in affecting output and ultimate unit labor costs, that several charts covering actual

FIG. 5—IRREGULAR TIME IN MAKING STANDARD TRIP

The distance between the parting and the tippie is fixed and barring congestion at the latter, the time between trips should be equal, yet here the time of trips varied between twenty-six and seventy-nine minutes.

experience in the mine will be given for the purpose of showing the possibility of constructive progress. It is probable that these cases represent conditions if anything slightly better than average in the mine observed because it is natural that when operations are being timed the management and men should be interested to make a good showing.

Studies of the number of cars on partings from

which the main-line locomotive takes the loads are shown in Figs. 1 to 8. These diagrams exhibit graphically the number of loaded mine cars and empties during a day at partings in four representative mines the haulage conditions of which were analyzed. Horizontal distances in the charts represent the time of day and the vertical distances show the number of cars on the parting.

The horizontal distances between the longer vertical lines show the elapsed time between the arrivals of the loaded trips of the main-line locomotive at the parting, and the length of these longer vertical lines in each case shows the number of loaded cars taken per trip. The jogs represent the delivery of loaded cars or the removal of empty ones by mules or gathering locomotives.

Fig. 1, representing half a day, shows that there were twenty-one loads on the parting at the beginning of the day, that the time between the trips of the main-line locomotive was fairly uniform and that on

FIG. 6—GRAPH SHOWING EMPTIES HELD AT PARTING

This shows that the empties at the parting made a bad start. This parting is the same as that for which Fig. 5 shows the tale of loads. For 50 minutes in the first hour and a half there were no empties on the parting track and motormen were waiting for some to arrive. After that there were always more empties than the trips could remove.

each trip out the locomotive took all the loads on the parting, varying from eighteen to twenty-nine.

Fig. 2, which is for the same mine, shows four periods in four hours during which no empties were standing on the parting. During three of these periods drivers and mules were idle waiting for cars.

Fig. 3, which is for another mine, shows a large accumulation of loads (ninety-seven) on the parting at starting time, due chiefly to coal being loaded on the previous day when the mine was idle. Note also, how

FIG. 7—FLAT PEAKS SHOW DELAYS ON MAIN ROAD

Mules brought in the loads to this parting and it is easy to see that they did it till there were no more empties to take away. Then came a long wait for the locomotives. Sometimes it was an unusually long one, as when the trip was away one hundred and one minutes. Fig. 8 shows that one mule must have gone away on that occasion without empties to gather a trip of loaded cars.

FIG. 8—GRAPH EXPLAINING FLAT PEAKS IN FIG. 7

The hollows in this graph correspond to the flattened peaks of Fig. 7. The quickened trips of the locomotives in the afternoon kept empties on the parting from about 1.20 p.m. till quitting time.

irregular was the time between main-line haulage trips—varying from eight to forty-five minutes—and the number of cars hauled—from thirteen to fifty-five. Sometimes the trip was pulled by one and sometimes by two locomotives.

This same mine, in Fig. 4, shows no empties at all delivered to the parting for forty-five minutes after starting time. Seven haulage locomotives with fourteen drivers and tripriders were idle during this entire period. Forty-five empties were then brought in but were all taken out by the gathering locomotives within twenty-two minutes and another period of twelve minutes of waiting ensued. By the end of the day there were fifty-three empties on the parting, and the following morning at starting time the haulage conditions at that parting would be the complete reverse

FIG. 9—CUMULATIVE RECORD OF LOADS GATHERED

The record of each locomotive is separately recorded. No. 17 was a consistently dilatory load gatherer to a degree not explicable by its greater length of haul. Unless it had peculiarly difficult grades it must have been out of condition, must have had derailments or been manned by a singularly inert motorman. The record seems to show in partial excuse, however, that he failed to get loads till a late hour and may have had to wait for empties.

of the day shown; the parting being full of empties and only sixteen loads waiting, in contrast to no empties and ninety-seven loads at the start of the former day.

Fig. 5 shows in another mine a pronounced variation in time between main-line haulage trips, varying from twenty-six to seventy-nine minutes.

In Fig. 6, for the same mine, the gathering units waited fifty minutes for empties during the first hour and a half. After that the supply was steadily in-

creased and from eleven o'clock on there was a surplus supply of from eight to twenty-two empties, more than were needed by the haulage locomotives. Whether the surplus at this parting was resulting in a shortage at other partings at the same time is not known.

FIG. 10—ANOTHER RECORD OF LOADS GATHERED

This also is cumulative. It is clear that the twenty-three men dependent on locomotive No. 7 got poorer service than the nineteen men who were served by locomotive No. 3.

Fig. 7, which represents conditions at a parting in a fourth mine, shows a variation from forty-eight to one hundred and one minutes between the arrival of main-line locomotives, and, as is shown in Fig. 8, not only was there a big variation in the time between the arrival of empties but a comparatively long wait for the mule drivers after each of the haulage locomotive trips due to the fact that there were no cars on the parting. The first three of these periods of waiting did not, however, cause loss of time to the miner. The miner began to wait for cars about 11:30 a.m.

The difference in the number of loads hauled by mules or by gathering locomotives to the same parting in three different mines is shown in Figs. 9 to 11. The variation in the number of cars gathered by different mules or locomotives in the same mine is marked, but not all explained by the differences in the distances hauled or the grades to be surmounted. The time that a locomotive or mule spends in traveling is much less

FIG. 11—WHERE GATHERING WAS BY MULES

Here also the mule with most places to serve gathered least loads, suggesting a need for a better arrangement of service.

than generally appreciated by the foreman or others who supervise mine hauling. This is particularly well borne out by Fig. 9. The gatherings of seven different locomotives to one parting are shown on this chart by accumulative plotting of the loads brought in from the time of starting until the last trip made by each locomotive.

It will be noted that locomotive No. 17 brought in only twenty cars, whereas the others hauled from forty-eight to seventy-eight. When the foreman was asked during the day why No. 17 was apparently bringing in so few trips his reply was "Oh, he has to gather way down in the south entries, and has a much longer distance to travel than the other locomotives." The actual average difference in distance of travel between locomotive No. 17, which brought in twenty cars, and locomotive No. 15, which brought in seventy-eight cars, was not over 900 ft. per trip.

The rate of travel of these locomotives was approximately 600 ft. per minute. The additional time, therefore, that should be allotted No. 17 for gathering greater distance would be only nine minutes for six trips. The fact that it consumed almost four hours more seemed perfectly natural to the foreman, and no effort was made by him to change the condition. Similar variations are shown in Figs. 10 and 11.

German Coal-Toasting Plant Has Scraping Gear to Clear Carbon Scale on Cylinder

A LONG slowly revolving horizontal retort is used in the Fellner and Ziegler process for the low-temperature carbonization of coal. Through this retort coal, crushed to about 1-in. cube, travels continuously, being heated externally by gas from a producer or by the rich gas evolved in the process. The temperature of carbonization is about 1,119 deg. F. (600 deg. C.). The retort is a steel cylinder, 65 ft. 6 in. long and of 8 ft. 3 in. internal diameter, inclined 1 ft. in 20 downward toward the discharge end, and set in suitable brickwork combustion chambers. It is revolved by suitable gearing which is actuated by a 40-hp. motor at the rate of about one revolution in 3 min. 25 sec. The output is three tons of coal per hour. Inside the first 23 ft. of the cylinder is a mechanical scraping gear, consisting of a number of arms projecting from a central revolving shaft, and extending to within $\frac{1}{2}$ in. of the inner surface of the cylinder. This detaches partly carbonized material which is deposited on the plates and which, if not removed, would soon reduce their conductivity.

The low-temperature fuel, with about 19 per cent volatile matter, is chiefly gasified in producers, and the small breeze is mixed with pitch and briquetted, or burned as pulverized fuel.

SALT AIDS MINERS TO ENDURE HEAT.—In England. George S. Rice, chief mining engineer, U. S. Bureau of Mines, had the opportunity of observing the experiments being made at Oxford and Birmingham universities into the health and working capacity of miners employed in excessively hot mines. As the result of the researches of Dr. J. S. Haldane, eminent mine physiologist, it has been developed that miners working in hot atmospheres lose chlorides rapidly, which is very weakening. The energy of the workers, it has been found, to a large extent can be re-established by the taking of salt in water, or through other liquid.

Is the Coal of Vancouver Island Nearly Exhausted?

Canadian Government Bulletin by the Late
J. D. MacKenzie Shatters Previous Beliefs—
Finds Only One-Sixth of Expected Reserve

BY F. H. MASON
Victoria, B. C.

"THE Coal Resources of Southern Vancouver Island", a government publication of which, as yet, only advance mimeographed copies have been issued by the Canadian Geological Survey, will tend to shatter preconceived ideas about the vastness of the coal reserve on that island. It indicates the presence of but one-sixth the coal supposed to have been available.

The memoir is so important that perhaps it will be well to say a word or two about the author, the late J. D. MacKenzie, who died last autumn as the result of a surgical operation, performed with the object of drying up a wound in the left lung; the wound was received in Flanders in 1917 and had not healed. Post-mortem panegyrics from colleagues on the staff of the Canadian Geological Survey and on that of the Massachusetts Institute of Technology and from geologists and mining engineers with whom he had come in contact all proclaimed MacKenzie as a painstaking and conscientious observer who was ever careful to take all possible precautions to verify his facts before arriving at definite conclusions.

NOT LIKELY TO MEET WITH APPROVAL OF PUBLIC

The field work on which the conclusions set out in the memoir are based was performed during the years 1921 and 1922, the last work done by the author, and in this work he had the wholehearted support of practically all the mining engineers now operating in the field. Records of boreholes and development and all available data were thrown open for his inspection; he had the run of the mines and surface croppings, and every aid that a generous and busy body of men could be expected to offer to a colleague. It will be well to bear this in mind, because the memoir is almost sure to meet with considerable opposition from some quarters. None of us likes to have his idols ruthlessly shattered, and MacKenzie's estimate reduces the present actual coal reserve on Vancouver Island to such proportions that, instead of its end being reached in some hazy, distant future that will trouble only our remote progeny, at the present rate of output the end will come during the lives of many now living. This statement, of course, refers to actual, not to probable and possible, reserves, some of which latter two are certain to be developed into actual reserves before the present actual reserves are exhausted.

MacKenzie reviews the work of previous observers—James Richardson, in 1871; George M. Dawson, in 1885, and C. H. Clapp, in 1911—the records of whom have appeared in publications of the Canadian Geological Survey, and he gives to each full credit for work performed often under exceedingly difficult conditions. Richardson examined the coast line from the head of Comox harbor to Victoria and that of the adjacent islands; he also traversed the rivers and creeks and the few trails available at that time.

In a map accompanying his final report (Geological Survey of Canada Report of Progress, 1876) he colored

COAL-RESOURCE MAP OF VANCOUVER ISLAND, B. C.

This map, made before the report was rendered by J. D. MacKenzie, shows the coal fields of Vancouver Island as they were believed to exist before his inquiry. Black shows anthracite and bituminous-coal areas and the cross hatching, beds that might bear such deposits.

a strip of land from the head of Comox harbor to the head of Sanich peninsula, some 130 miles in length, as being underlain by productive coal measures. The northern half of Saltspring Island and the adjacent islands to the north also were so colored. Evidently Richardson based his theories on the knowledge geologists had at that time of the more regular coal measures of the Carboniferous series in Nova Scotia, and he believed that the seams he had found along the coast would persist for great distances under the water and that other seams would be found below them.

"As a matter of fact," MacKenzie wrote, "the progress of exploration during the last fifty years has made it clear that there are only three principal coal-bearing zones in all this area, and that even those zones are not always productive. Further, throughout a great part of the area only one zone exists, and in the remainder only two of the three are found. Instead, therefore, of the probability of finding coal throughout a zone of rocks more than 100 miles long and covering a large area along the southeastern coast of the island, it is now known that the areas from which future production is likely to come are relatively restricted."

Dawson, who went over the ground in 1885, seems not only to have supported Richardson's findings but to have supposed that the coal-bearing area extended inland from the Campbell River in a northwestern direction to the Salmon River, a distance of 35 miles, thus greatly extending the productive area, a supposition, however, that MacKenzie has shown to be incorrect. Clapp's estimate, made in 1911, MacKenzie found to be altogether too optimistic.

As has been hinted, MacKenzie's findings are likely to meet with some opposition, but those who may wish to controvert them will find themselves facing a difficult proposition, for this survey, like all those made by MacKenzie, is thorough. He lucidly defines what he means by actual, probable and possible coal, and he states clearly how he has reached his conclusions. He takes the two main areas, subdivides them into lesser areas, and measures the various seams in each division.

In this way he finds that the Comox area contains 18,900,000 tons of actual, 39,000,000 tons of probable, and 245,230,000 tons of possible coal in seams thicker than 3 ft. and 12,000,000 tons of actual, 50,050,000 tons of probable, and 181,000,000 tons of possible coal in seams between 1 and 3 ft. thick.

In the Nanaimo area he finds 34,070,000 tons of actual, 67,220,000 tons of probable, and 68,000,000 tons of possible coal in seams more than 3 ft. thick and 7,802,-

000 tons of actual, 20,842,000 tons of probable, and 122,000,000 tons of possible coal in seams of between 1 and 3 ft. in thickness. To the quantity in the Nanaimo area he adds 35,000,000 tons of possible coal below 2,000 ft. in depth. In the Cowichan area he finds no available coal; in the Gulf island area, none; in the Alberni district—who knows?

Thus he finds a total of only 52,970,000 tons of actual coal in workable seams—that is, 3 ft. or more in thickness—and a grand total of 835,000,000 tons of possible coal—about one-sixth of the previous estimate.

But worse is yet to come. The foregoing estimate is of the quantity of coal in the ground. With regard to the mining of it MacKenzie said:

"It does not follow that anything like this quantity is available for recovery under present conditions of mining or under the conditions likely to obtain for some time to come. In the first place, it is only under exceptionally favorable conditions (which are, unfortunately, only too rare on Vancouver Island) that seams of less than 3 ft. average thickness can be profitably mined. Furthermore, the expense and difficulty of exploration, development and operation at depths exceeding 2,000 ft. prohibit economical production.

"Again, the coal in the ground and the coal that the mine reasonably may be expected to produce are not the same thing. There are always losses—sometimes large losses—incidental to mining. A certain quantity of coal is left in pillars too thin to remove or is crushed by movements of the strata after the surrounding coal has been extracted. Every coal miner on Vancouver Island is only too familiar with the 'rolls' and 'pinches' that have made the extraction of coal from certain areas of the mines impracticable, if, indeed, the movements of the overlying rocks have left any coal in these thin places. Some areas are so broken by faults that economical extraction is impossible.

"In one district knobs of the underlying barren pre-Cretaceous rocks project through certain parts of the seam. These knobs not only form areas of no value in themselves but by their effect on the seam as it approaches these old shore lines, interfere with the placing of haulage roads and their ventilation. Large areas of coal may be lost by mine fires, by excessive gas, by water, or by other causes. It is no exaggeration to state that in large areas of some of the Vancouver Island mines barely 50 per cent of the coal developed and actually found in the ground has been extracted, because of conditions quite beyond the control of the operators."

Coal-News Gatherer Finds A Near-Paradise In Cardiff Exchange

Leaders in Busy British
Coal Marts Descant Freely
on Varied Phases of the In-
dustry—All Eager to Help

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

FUEL DISTRIBUTOR WADLEIGH telephoned me one day shortly before I left for Europe and asked me to go over to his office to meet a man prominently connected with the British coal industry. On arriving there I was introduced to S. A. Bacon, one of the partners in the firm of D. L. Flack & Son, Ltd. When I told him of the trip I had in prospect he offered to do all within his power to help me and suggested that I call on him immediately on my arrival in London. He was so evidently sincere in his offer that I accepted his invitation and was in his office before I had been many hours in the British metropolis. He all but suspended his business for the day. I know he answered two hundred of my questions, but when I left his office I had a clear mental picture of the existing situation in the British coal fields, as well as a background that was to stand me in good stead afterward.

The next day, at his suggestion, I returned to his office and discussed with the various specialists on his staff their respective branches of the work. This gave me an insight into the problems of marketing, bunkering, chartering and rail transportation.

On the day following I left London for Cardiff. Mr. Bacon had advised his Cardiff office as to the purpose of my visit. On my arrival there, S. H. Lewis, in immediate charge of the South Wales operations of Flack & Son, had everything ready to put me in immediate touch with the best sources of information. To see that I was introduced properly, he unloaded his duties for the day on his efficient Mr. Larkin, and took me on to the floor of the coal exchange. He had arranged that I be accorded the privilege of the floor.

If there is a paradise for the gatherer of coal news, it will be something like that Cardiff exchange. Here all those interested in buying, selling or transporting coal put in an appearance at some time during the day. Here the dealing for most of the coal is carried on. Comparatively little business is done over the telephone or by calls at offices. There is a social feature, too, about the exchange. Whether members have coal to sell or not they put in an appearance and hear all the talk that is going the rounds. I will go into the details of the operation of this exchange in a separate article.

I was in clover on the floor of that exchange. I would talk a while with one man and then ask him to introduce me to someone else near by. In this way I was able to get the viewpoints of ten times as many men as I could have looked up at their individual offices.

In addition to my visits to the floor of the exchange, I had the advantage of a personally conducted tour of the harbor, with Mr. Lewis doing the conducting. His wide knowledge of chartering and bunkering brought out many interesting points about the conduct of the greatest coal-shipping port in the world.

I was anxious to get the railroad viewpoint, par-

ticularly with regard to car supply and distribution, and the effect on the coal industry of the consolidation into one system of all the lines of south Wales and southwestern England. This information was supplied by W. S. Horace Williams, assistant superintendent of the Great Western stationed at Swansea, and by officials of the road to whom Mr. Williams referred me.

Since the Northumberland and Durham fields present other aspects of the British situation, I journeyed to Newcastle-on-Tyne. Here again was that splendid facility, the exchange. There I was taken in tow by the Newcastle representatives of D. L. Flack & Son. Through the personal kindness of T. B. Charlton and H. E. Dodd I came in contact with the men most familiar with the various phases of the industry there.

Herbert Shaw is the secretary and mainspring of the Newcastle exchange. If I had my way about it, I would establish a coal exchange at Norfolk and import Herbert Shaw to manage it. If the industry will conduct a fair experiment with such an exchange here, the institution is certain to thrive and in my opinion yield 1,000 per cent dividend in service and convenience, to say nothing of the stabilizing effect on prices.

NEWCASTLE FORTUNATE TO POSSESS RIDLEY WARHAM

In Newcastle I met a man who impressed me as being a particularly great asset to the district. He is Ridley Warham, of the Ashington Coal Co., Ltd. His clear thinking and willingness to insist at all times that the industry be conducted on the highest possible plane has made him a great influence for good in the Northumberland and Durham fields. Many of the thoughts which he presented will appear in the articles to follow. I made note of every word he told me and while I promised not to quote him, every sentence that he uttered will find its way into these stories.

I did not call on Sir Richard Redmayne until I had completed my visits to the coal fields. I knew in advance that he could explain any point on which I was not clear, and then, too, I wanted to take advantage of his vision and his knowledge of the economics of coal when I would be in a position to ask more intelligent questions and when I would have the background to understand better what he would tell me.

There again I met with the strict injunction that it would be better to use his thoughts rather than to attempt any quotations. By giving this promise, I am sure I obtained a great deal of information which would not have been forthcoming otherwise. In this particular, the contrast between the British desires and those of many of our men in prominent positions is particularly striking. On Capitol Hill, in Washington, most men feel aggrieved if they are not quoted.

[Next week Mr. Wooton writes of transportation and wage problems in Great Britain's coal industry.]

Automatic Track Switch

THE automatic switch thrower is a labor-saving device designed to do anything a switchman can do with a switch. The device consists of four distinct units, which operate in conjunction with each other to perform the particular work for which they are designed. A device called a traveler is attached to the most convenient place that may be found on the side of the locomotive, and is operated directly with the hand, or if out of reach of the hand, as it is most frequently installed, a rod is connected to the handle which is within reach of the motor runner. An operating device is installed alongside the outer edge of the track rail, attached securely to the rails and resting on the ties. A tripper is installed in the same manner as the operating device. A bell crank to which are attached rods connecting with the operating device is fastened to the track rail and controls the movement of the switch points.

If the switch is set normally for the straight track and the motor runner wishes to go into the parting through the switch he merely pulls the handle on the traveler, which causes the plunger to descend to a level with the bottom plate of the operating device, and as this plunger passes between the two guides on the operating device, it pushes a lever which actuates the bell crank at the switch points, thus opening the switch, which remains in that position until it is desired to close it. The motor runner releases the handle and a spring pulls the plunger back to the first position, so

AUTOMATIC TRACK SWITCH IN OPERATION

Safety, convenience and economy are the goals sought by the increased application of automatic equipment in the mines. This device makes a bid for a place in the long list of successful labor-saving appliances.

that it passes over the tripping device without disturbing the switch.

The tripping device may be located at several points, depending upon how it may be desired to close the switch. It can be set a distance beyond the switch points equivalent to the longest trip, so that it may be closed after the trip has passed through, or it may be set in advance of the operating device, so that other trips which follow may close the switch should they desire to proceed over the straight track. If the switch is closed after the trip has gone into the switch, it will pass out as a spring latch, or if it is opened and a trip wishes to come out on the main track, it likewise passes through as a spring latch.

When it is desired to install this switch thrower for making flying switches, the tripping device is installed at a point beyond the switch points, so that just as soon as the rear wheels of the locomotive pass through the switch, it will close, permitting the car or trip to take the other track, even if the first car is against the bumper of the locomotive.

The mechanism of the different units is so constructed that they can be adapted to any variation in the track or manner of switching which they may be called upon to care for. The traveler and operating device may be placed on the opposite side of the track if necessity requires and with a few modifications in the working parts it will operate equally as well.

When installed on a grade as a safety measure against runaway cars or trips, a back switch is installed if sufficient room can be found; otherwise, a short track will divert the cars from the main track leading them into the rib where they will be stopped before any great momentum is acquired. In cases of this kind the switch is always open against the descending trip, which has the tripping device installed just ahead of the switch points. The descending trip closes the switch with the tripping device. The switch thrower is installed at a point equal to the length of the longest trip, and after the last car has passed the switch points the switch is again opened.

While the switch thrower is primarily designed as a safety device, it possesses valuable economic features by way of power saving. By eliminating the necessity of stopping the trip to permit one of the trip crew to run ahead and throw the switch, it reduces the amount of power required to move the trip by eliminating unnecessary acceleration peaks.

The elimination of the stop also saves the wear on brake shoes, tires and rails; saves the tear on locomotive and cars from jerking and bumping.

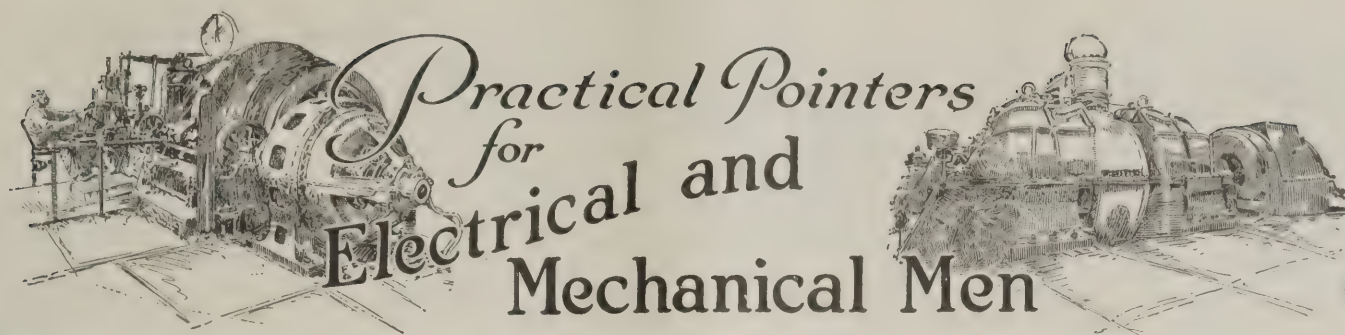

One of many of these automatic switch throwers has been installed by the American Mine Door Co. of Canton, Ohio, the manufacturers, at the Bureau of Mines Experimental Mine at Experiment, Pa.

Here are a few figures that tell a big story—How the soft coal operator has kept costs as low as he has with mounting wages.—From U. S. Coal Commission Report on Engineering and Management.

Make Rolling Stock Carry Safety Message

W. C. HOLMAN, chief engineer of the Stag Canyon Branch of the Phelps Dodge Corporation, Dawson, N. M., sends the illustration accompanying this article informing us that posters are glued to the sides and ends of the mine cars and the sides of the locomotives and are covered with a coat of white shellac. He says: "Usually a poster is pasted on each car and motor. We term the posters 'Silent Foremen.' Some

USING MINE CARS AS SANDWICH MEN

The cars with their silent warning do not wait at a respectful distance from the drift mouth but on every trip each one singles out his man, enters his room and gives him the warning.

of the posters in use are: 'Be Careful of Your Eyes'; 'Look Out for Your Fingers and Toes'; 'Take Down That Loose Roof'; 'Set that Prop Now'; 'Is That Prop Too Close to Track?' 'Don't Let Machine Jack Slip'; 'Don't Get Squeezed.'"

What's the Trouble with Mine Power House? Why Not Modernize It?

I AM a new man to the coal industry, having been connected with it for only a short time, and naturally I have much to learn about it, but I should very much appreciate some enlightenment as to why there apparently is such a notorious lack of understanding of modern power-plant practice and such a waste of power about bituminous-coal mines as exists in certain fields.

In the last few months I have visited over twenty mines the daily output of which ranges from about two thousand to approximately six thousand tons and at many of these mines there was a shortage of steam-generating capacity or electric-generating capacity or both, this shortage of power being so acutely felt that the management was either putting in or figuring on putting in public-service power, using motor-generator sets to furnish direct current for mine work, while enormous quantities of exhaust steam was going to waste in the atmosphere.

The majority of the mines were generating d.-c.

electric power with automatic engines running non-condensing. In fact, not a single condensing engine was seen, although three turbines, two of which were mixed pressure, were found, and of course these were operating condensing. Plants with sufficient steam going to waste to generate from 500 to 1,500 kw. of current on low pressure steam were no uncommon sight. What is the reason for this? Is the mixed-pressure turbine a failure, is the mine management asleep, or can a public utility company sell power for less than it can be made at the mine?

Some mines were hoisting from deep shafts and were putting out over six tons of coal per boiler horsepower and had plenty of power, while others were putting out less than two tons per boiler horsepower and then were short of power.

The total boiler capacity of the mines was about evenly divided between fire-tube and water-tube boilers, the fire-tube boilers being hand-fired and the water-tube boilers being generally stoker-fired, chain grates being used, yet the modern boiler plant was often furnishing steam to ancient engines.

The caustic comments of some of the members of the U. S. Coal Commission can well be appreciated after visiting the mines, but how is the matter to be remedied? Talk about Rip Van Winkle being behind the times! Rip had nothing on these fellows when it comes to being asleep on power.

Think of carrying direct current a mile and a half to the face, generating it with automatic non-condensing engines, operating a fan on 24-hour service and running it with a plain slide-valve engine taking its steam through a line 300 to 500 ft. long, generating the steam at 125 lb. gage pressure or less, without superheat, in boilers that have brick settings without a sign of mastic cement or other coating to stop air leaks, and wasting 75,000 to 400,000 lb. of exhaust steam per working shift from a hoisting engine and using live steam to heat the wash water for the miners and then wonder what is the matter with the power plants of the mining industry! The average plant is a joke, for which the owner pays dearly.

Pittsburg, Kan.

IRA A. BUTCHER.

There is no doubting that many mining-power plants have become old and inefficient. Investigations by individuals and commissions have brought to light many instances of gross waste. Then again there are some mining properties where the saving in the power-house equipment is a big factor in placing the mine on the proper side of the ledger.

There is much to be done, however, in more efficient consumption of coal at the mines, in the industrial plant and in the home. Fortunately, the mine manager has many high-class central station plants and many highly developed mine-power plants, recently installed,

from which he can pattern his own plant. Big developments are sure to come along this line, rapid advancement in efficient combustion of fuel and a multiplicity of devices for generating steam and using it economically are already available and in successful operation.

It would be most interesting for our readers to discuss these points which lead the way to greater production of the mine with less worry and fewer shutdowns.

Repairing Badly Cracked Engine Cylinder

RECENTLY a cylinder of a 24x48-in. hoisting engine was badly wrecked by water entering the cylinder. It was impossible to obtain a new cylinder without considerable delay so it became necessary to make a hasty yet safe and efficient repair.

As shown in the figure the cylinder was cracked in three different places and it is interesting to note how each crack was repaired because each was a somewhat special job in itself.

Crack A, which will be noticed between the cylinder and valve chest, extended back 8 in. to the port chamber. In repairing this crack a steel link was shrunk in the surface of the metal to close the crack. This link was about 1½ in. long.

Crack F was 3 ft. long and extended from the center of the top of the cylinder to the drip tap at the bottom.

SHRINKING LINKS AND SPOT WELDING KEPT THIS CYLINDER IN OPERATION

The cracks were closed and a temporary repair effected with little loss of time.

It was closed by shrinking in links as shown by the dotted lines.

In both these repairs the links were spot welded and the outside of the cracks closed by the same process.

Crack D started at the front head and extended 18 in. through the top of the chamber which connects the valve chest and cylinder. This crack was chipped out into a V shape and closed by first inserting a row of ½-in. studs on both sides and then tying the studs and sides together by welding.

Because of the shape of the casting it was impossible to run studs from the front to the back head so the above method was used.

At present this engine is running with normal load and shows no sign of weakening.

An Efficient Method of Cross-Bonding

IT IS always difficult to explain the operation and the reason for certain things to men unacquainted with the theory of electricity. Every mine electrician knows the advantage of good bonding of the tracks wherever mine locomotives are used or other equipment is operated from the trolley circuit and the return made through the rail. However, this is one case where it is far from easy to explain the advantages of good bonding to the layman. To anyone familiar with resistances it is easy to show the high power losses which result from poor bonding. There are many other disadvan-

A CROSS-BOND THAT BONDS

The necessity of having cross-bonds increases with the number of turn-outs as usually it is here that open circuits occur in the track circuit.

tages of poor bonding, principal among them being loss of voltage. After a pair of rails have been well bonded, considerable attention should be given to cross-bonding.

Because of their particular location cross-bonds usually are likely to be cut or torn loose in the event of an accident. The accompanying sketch shows an application of the cross-bonds which we have been using to great advantage. It will be noticed that only the welded terminal is above the top of the tie, and owing to the fact that this weld usually is very strong it is practically impossible for it to be knocked loose. The particular advantage of this method of installing the bond is that all the cable is well protected from being cut. Care and consideration should be exercised in fastening the bond to the tie. If this is properly done it will rarely come loose, and, therefore, cause little trouble.

WEST VIRGINIAN.

Maximum Current-Carrying Capacity of Bare Copper Conductors Used in Mines

THE Standardization Division of the American Mining Congress has adopted the following table covering the maximum current carrying-capacity of bare copper conductors used in the mine:

Size of Conductor B. & S. Gage	Current Capacity Amperes	Size of Conductor Circular Mils	Current Capacity Amperes
10	80	250,000	690
8	105	300,000	790
6	145	350,000	880
4	210	400,000	965
2	280	450,000	1,050
1	320	500,000	1,140
0	375	550,000	1,215
00	435	600,000	1,285
000	525	650,000	1,370
0000	615	700,000	1,450
		750,000	1,520
		800,000	1,590
		900,000	1,730
		1,000,000	1,870

USE SEAWEED FOR BRIQUETTING BINDER.—Report declares that a factory is to be erected at Stromness, in the Orkney Islands to the north of Scotland, for the manufacture of briquets from the coal dust and the colliery waste of South Wales, the binding material being a special kind of seaweed found in enormous quantities near the islands. *The Engineer*, which contains the information, states that the report is unconfirmed.

Problems of Operating Men

Practical Notes on the Safety of Flame Safety Lamps

Low Flame Safer Than High Flame in Testing for Gas—Origin of the Idea—Protective Value of Burned Air at Top of Chimney

IN THE report of Inspector of Mines, Henry Devlin, made recently on the Wakesiah explosion of Nov. 24, 1922, Nanaimo, B. C., it is stated that, as a result of the disaster, the management have decided that all firebosses must carry two lamps, a Wolf safety lamp, having the flame set very low for use in testing for gas, and an electric headlight for illuminating purposes.

It will be remembered that this question of firebosses carrying an electric cap lamp was broadly discussed in *Coal Age*, recently. I think there can be no doubt but that the majority opinion favored the carrying of an electric cap lamp, in addition to the safety lamp needed for testing for gas. The principal argument against the cap lamp was the claim that the brightness of the light obscured the test for gas.

Incidentally, however, the ruling of the management has an important bearing on another point in controversy, regarding the use of safety lamps in making the test for gas. The requirement in the ruling that the lamp wick be "set very low" calls to mind the claim made by a previous writer, in *Coal Age*, that a high flame carried in a safety lamp was safer than a low flame, provided the lamp did not smoke.

TRACING ORIGIN OF LOW TESTING FLAME

Inasmuch as the advocacy of a low testing flame is not confined to mine officials in British Columbia, it is worth while to ascertain on what basis the claim is founded. Going back in the history of the safety lamp, we find that the practice of lowering the wick flame when about to make a test for gas, existed from the time the single-gauze Davy lamp first came into use.

The practice followed, as a sort of natural sequence, the common custom of the early firebosses, who made the test for gas with a bare candle, reducing the wick to a single thread, in order to give the least possible illumination and heat.

When safety lamps protected by wire gauze first made their appearance in the mine, the habit of lowering the flame continued, largely because the small non-luminous flame made the flame cap more visible. At that time, the luminosity of the flame could only be reduced by lowering the wick.

For many years, the general opinion prevailed that there was an element of danger in increasing the lighting value of a safety lamp flame above 0.26 of a standard sperm candle. Later experience has proved, however, the absolute necessity of providing the miner with a better light, as a means of reducing the number of

accidents from falls of roof and coal. On that account, the illuminating power of safety lamps has been gradually increased by various means, without impairing its safety value.

Today, it is possible for a miner to use a safety lamp of two standard candlepower, with greater safety than was formerly afforded by the use of a lamp of less than $\frac{1}{2}$ cp. Even allowing that the modern safety lamp is a hotter lamp to handle than one of the old construction, yet the heat is so disposed that the gauze cannot become dangerously heated when the lamp is properly handled.

IMPORTANT PRINCIPLE OF STEPHENSON LAMP

Before closing, allow me to draw the attention of those who think that the only safeguard of a bonneted Wolf safety lamp is the cooling action of the wire gauze, and remind them that the burnt air consisting chiefly of carbon dioxide and nitrogen has a strongly protective value confined in the top of the lamp.

This was the principle of the old Stephenson safety lamp and has not been forgotten in the construction of our modern lamps (*Mine Gases & Ventilation*, Beard, p. 268). So great is the importance of this principle that the possibility of a dangerous explosion within the chimney of an approved safety lamp is practically eliminated in its careful use.

My argument is that increasing the illuminating value of a lamp gives a larger percentage of carbon dioxide through the increased combustion of the wick flame and the safety value is increased at the same time. Barring the presence of coal dust, my conclusion is that it would be impossible to obtain a condition that would cause the intense heating of the upper portion of the gauzes in an approved safety lamp as, I believe, was claimed by a witness in the Wakesiah inquiry.

JAMES ASHWORTH,
Mining Engineer.

Cowley, Alta, Canada.

Faults of Erosion vs. Displacement

Finding the coal beyond a fault not always a simple matter—Faults of erosion very common in the mining of coal—Rules that apply to faults of dislocation are no help in such cases.

LOOKING through the columns of *Coal Age*, recently, I ran across the letter of M. C. Butler, discussing the question of "Normal vs. Reverse Faults in the Mining of Coal," in the issue, Oct. 4, p. 519. Apparently, Mr. Butler refers only to faults of dislocation.

Viewing the matter from a practical standpoint, namely, that of a miner running up against a fault that has cut out the coal, that writer says, "The solving of the problem, as it occurs in coal measures, does not require a technical education," adding, "As far as the practical miner is concerned, it is simply a matter of observation and the following of a simple rule."

In my experience, faults of displacement to which normal and reverse faults belong are by no means the commonest type of faults found in bituminous coal seams. The type most frequently encountered, in the mining of bituminous coal, is that in which the coal has been eroded by some natural agency, causing what is commonly known as a "fault of erosion."

FAULTS OF EROSION, SO TO SPEAK, DIFFER FROM FAULTS OF DISPLACEMENT

It is evident that no simple rule will apply to this type of fault, where the coal-forming material has been cut out either by a stream flowing through the partially decayed vegetable matter, before it was covered by subsequent deposits. Or, the topography of the land may have been such that a hill or roll, being elevated above the general level of the basin or swamp, interrupted the continuity of the coal bed.

In one instance to my knowledge, there were indications of the erosion of the coal-forming material, caused by a stream that had flowed through the basin. In its flow, the stream had cut out a strip a mile in width and 12 miles long, across the entire basin and later the cut had been filled with material that formed a sandstone.

Simple rules that apply to faults of displacement do not help one to locate the coal when the fault encountered is one of erosion such as I have described. In my opinion, too much emphasis is often placed on rules given in textbooks, which seem to convey the idea that it is a simple matter to find the coal if the rule is followed. Much to his disappointment, the young engineer is often misled and finds, too late, that it is not nearly as simple as the textbooks explain.

CHARLES E. LAWALL,
Asst. Prof. of Mining Engineering,
West Virginia University.

Morgantown, W. Va.

Blasting Out Timbers Dangerous Practice

Fine dust lodged in timbers readily ignited by the high temperature and intensity of the flame of the dynamite charge. Instance cited of explosion caused by blasting timbers.

REFERRING to the letter of Oscar H. Jones, *Coal Age*, Sept. 20, p. 440, in which he comments on the practice of blasting out timbers, as mentioned by a previous writer, I heartily agree with him that the method is not safe and other means of removing timbers should be used.

Putting it a little stronger, I consider such practice extremely dangerous in a dry and dusty mine, as the high temperature of the flame and gases emitted by the explosion of the dynamite is liable to initiate a dust explosion with all its disastrous results. The mine timbers are always coated with dust, and moreover, the dust that adheres to the timbers is of the finest nature.

EXPLOSION OF DYNAMITE IGNITES DUST

By the force of the blast this dust is raised into suspension in the mine atmosphere and easily ignited by the high temperature of the gases and flame emitted by a charge of dynamite. Ignition of the dust invariably occurs when dynamite is exploded under these conditions in mine workings.

I recall a very disastrous explosion that took place some time ago in this state. (I have forgotten the

name of the mine.) Dynamite was used to blast out some timbers on a station at the foot of the shaft. The explosion wrecked the mine in that immediate vicinity and it was fortunate the blasting occurred when there were no men in the mine, or the loss of lives would have been truly appalling.

It was decided upon thorough investigation, as I recall, that the explosion was caused by the charge of dynamite emitting flames of sufficient intensity to ignite the fine dust that had lodged in and around the timbers and cribbing and lay on top of the same. As previously mentioned, this dust accumulated on the timbers, clinging to the roof and sides and lying on the floor is of the finest nature, and, by its absorption of the oxygen of the air it has been rendered highly inflammable.

CAUTION IN USE OF HIGH EXPLOSIVES

While in my past experience I have, at certain times, used high explosives to blast out timbers and induce a fall in pillarwork, I was always careful to see that the conditions were such as to eliminate the chances of an explosion and possibly a mine fire resulting from the ignition of the coal dust. I would warn anyone who attempted to use this method to be very careful and not, in any case, use dynamite. Instead use a permissible explosive, and see that the place is not dusty, in the section where the blast is to be fired.

The method suggested by Mr. Jones of using an 8-in. post suspended on a rope, which serves as a battering ram, appears to me as a very dangerous method. A person using an 8-in. post, swung on a rope attached to two convenient posts, must necessarily be very close to the post he is striving to discharge; and there is great danger that possibly, by discharging these posts, the unsupported roof behind is weighting and will draw back over the posts on which the battering ram is hanging and trap the man engaged in the work. Personally I favor the post-puller advised by the editor and illustrated on page 20, of the issue July 5, 1923, which is the Sylvester or Sylat type. It is important, however, to use sufficient rope to allow the operator to be in a place of absolute security.

Charleston, W. Va.

J. W. POWELL,
Shaft Contractor.

Retrograde of Mining Examinations

Recent examinations made easier than former tests—Reason for the change hard to understand—Effect of decline shown in various ways.

SOME references that have been recently made, in *Coal Age*, with respect to decreasing the number of mine accidents, have turned my thoughts toward one phase of the subject that I consider most important. In order to do effective work in keeping down accidents, we must strike at the root of the matter and do everything possible to secure capable and efficient mine officials.

It is with regret that I have observed a steady decline in the examination of candidates for the positions of mine foremen, assistant foremen and fire-bosses, in the bituminous field of Pennsylvania. It has been remarked by many that the examinations for the present year were not up to standard. The questions were much easier and required far less time to answer than questions asked in previous examinations.

Any one who considers the matter, naturally asks himself why it was the examination was made so much easier than heretofore. The purpose of the examina-

tion has not changed and yet, for some reason, the examining boards in the state appear to have lowered the standard. It might be assumed that the purpose in view was to obtain a larger number of men holding certificates, in order to reduce the number of uncertified men employed in an official capacity.

EASY EXAMINATIONS PRODUCE INCOMPETENT MEN

Again, a less plausible reason might be that the aim was to reduce the expenditure for the maintenance of examining boards. If that was the purpose, however, there is hardly a question but that the amount saved will be paid twice over in the increased cost of production and compensation for accidents, to say nothing of the coal lost beyond recovery by reason of poor management.

No one can consider for a moment that past examinations have been of too high a grade and that, in order to remedy the situation and secure a larger number of certificated men, it was necessary to make the examinations easier. We all know that would result in certifying incompetent men. Close observation of the coal mines of the bituminous field must serve to convince any one that the requirements of mine officials must be made more rigid than ever before if safety and economy are to be practiced.

The numerous recurring accidents in mines, together with the number of prosecutions for violations of the law and mining rules and regulations, and the increase in insurance ratings, which has been found necessary at some of the mines, all show the effect of incompetence and carelessness on the part of many mine officials.

NEED OF A HIGHER STANDARD

The recent report of the Coal Commission, regarding the amount of bituminous coal lost beyond recovery, is only another evidence of the need of raising the standard of examinations for mine officials.

If late examinations have been made easier for the purpose, as I suggested, of increasing the number of certified men, it must be admitted that the value of the certificate has fallen. We cannot expect to obtain something for nothing. If the certificate is to have any value, its possession must involve sacrifice on the part of the man who wins out. If gotten without sacrifice, the certificate means nothing.

Only a short time ago the majority opinion of writers who discussed the question of the certification of mine officials, in *Coal Age*, was strongly in favor of the certified man. Now, if the certified man is to be on the same level with the man who could not secure his papers under the old standard, I think the result would change the opinions of many of those writers.

It has been my fortune to attend three examinations in the bituminous field of Pennsylvania, from 1917 to 1922. In my opinion, none of those examinations was a bit too hard for a man seeking a real mining certificate. Far be it from me to find fault with any step taken for the betterment and welfare of the coal industry in our state and country.

The old saying comes to me: "As the teacher, so will be the scholar." I apply this rule to mine-official examinations. A poor examination is bound to turn out poor mine officials. My advice is to maintain the standard of mining examinations and make them more rigid, in the interest of safety and economy.

Mayport, Pa.

JAMES THOMPSON.

Inquiries Of General Interest

Exchanging a Four-Entry for a Two-Entry System

Four-Entry System Necessary in a Mine
Generating Gas—Roof Conditions Not Favorable
to Proposed Change Requiring Wide Entries

WE ARE working a very gassy mine that has been opened on the four-entry system. The seam of coal is about 42 in. in thickness and is overlaid with a very loose top of drawslate averaging about 3 ft. in thickness. Above that is a more solid layer of drawslate 12 ft. thick and over that again is solid sandstone. In working out this coal, the lower drawslate is first allowed to fall and loaded out of the mine. The upper drawslate, being more solid and making a fair roof, is then timbered with crossbars spaced 6 ft. apart. The four entries have all been driven 7x9 ft. in section, which makes the total sectional area of these entries $4(7 \times 9) = 252$ sq.ft.

With a view to reducing the cost of driving and maintaining these entries, it has been suggested to change the system and drive two entries instead of four, but making the entries of such size as will afford the same sectional area as the four original entries. This will require each entry to be 10x12.6 ft. in section. I want to ask if this change would be advisable under the prevailing conditions. Those who favor making the change claim that it will reduce the present cost of entry driving and the future cost of upkeep almost one-half what it is in the present four-entry system.

Trinidad, Colo.

SAMUEL BERKOVITZ.

The four-entry system is particularly adapted to the working of a gassy mine. It provides a separate return air-course for each side of the mine, while the two center entries are available for a haulage road and manway, respectively. Together, they furnish an ample intake area for the entire mine.

By changing this four-entry system to a double-entry plan, even allowing that the total sectional area for intake and return is not reduced, there are provided but single intake and return airways, which must also serve as main haulage road and manway. The plan calls for the building of the same number of overcasts and has no advantage in that respect over the four-entry system. The saving in cost of driving four main entries, instead of the two entries in the proposed plan, would probably be more than offset by the increased cost of upkeep in the double-entry system. The two entries will need to be wider and higher than in the old system and require the use of more timber at a greatly increased cost. Moreover, it is a question whether the roof conditions will permit of driving these wide entries. It is quite probable that the upper drawslate will be found far more difficult of support and give an increasing amount of trouble.

In any event, the question of furnishing adequate ventilation in this "very gassy mine" is the main consideration and of far greater importance than an

assumed saving in cost of driving two main headings instead of four. Regarding the advisability of making the proposed change, therefore, we fail to see any benefit to be derived therefrom; but, instead, foresee increased danger and cost of maintenance in the future operation of the mine.

Examination Questions Answered

Anthracite Foremen's Examination Districts 1 and 2, 1923

(Selected Questions)

QUESTION—*What are the requirements of the mine law when a workman is about to fire a blast? State fully.*

ANSWER—The General Rule 33 (Art. 11) requires that a workman about to fire a blast "shall be careful to notify all persons in danger therefrom, and shall give sufficient alarm before and after igniting the match, so that any person or persons who may be approaching shall be warned of the danger."

QUESTION—*If, on examining a mine map and measuring a place, on the map, driven from the gangway, you found its length to be $1\frac{3}{4}$ in., what would be the length of the place represented, the scale being 100 ft. to the inch and the place having an inclination of 50 deg.?*

ANSWER—A measurement of $1\frac{3}{4}$ in. on the map represents a horizontal length of $100 \times 1.75 = 175$ ft. The corresponding pitch distance is found by dividing the horizontal distance by the cosine of the angle of inclination. Thus $175 \div \cos 50 \text{ deg.} = 175 \div 0.64279 = 272.25$ ft.

QUESTION—*If the pillars in a mine are 8 yd. thick, at a depth of 300 ft., how thick should they be at a depth of 900 ft., under equal conditions?*

ANSWER—There are many conditions that affect and determine the size of room pillars, in mines, which make it impossible to give a reliable answer to this question. The physical conditions are, the character of the roof, floor and coal, as determining the ratio of pillar to opening. Other data concerned in the calculation are the depth of cover and the thickness and inclination of the seam. In a general way, the relative width of pillars may be taken as varying with the cube root of the square of the depth of the seam. In other words, the width-of-pillar ratio is equal to the cube root of the square of the depth ratio. In this case, the depth ratio is 300:900; or 1:3. Then, calling the required width of pillar x , at a depth of 900 ft., when the conditions call for pillars 8 yd. wide, at a depth of 300 ft., we have $x = 8\sqrt[3]{3} = 8 \times 2.08 = 16.64$ yd. This assumes that the thickness of the seam, the width of opening and the character of the roof, floor and coal and other data are the same in each case.

QUESTION—*What is the strain on a rope caused by a load of 6 tons on a slope pitching 25 degrees?*

ANSWER—Assuming that the given load of 6 tons is the load on the rope, the strain on the rope would be the same. The probable meaning of the question, however, is that the weight of the moving load is 6 tons and in that case the strain on the rope is the sum of

the grade and track resistances. Therefore, assuming a track resistance of, say 15 lb. per ton of moving load, the grade resistance being 20 lb. per ton, for each per cent of grade, or $20 \times 25 = 500$ lb. per ton of moving load, the total load on the rope is then $6(15 + 500) = 3,090$ lb., or 1.545 tons.

QUESTION—*How would you find the depth of a shaft having no chain or tape to measure it?*

ANSWER—The use of the aneroid barometer enables one to ascertain the depth of a shaft, with fairly close approximation, by taking a careful reading on the surface at the head of the shaft and another reading at the shaft bottom. These readings should be taken at the same time, or closely follow each other, to eliminate any possible atmospheric change that may occur in the interval between the readings. Also, it is necessary to shut down the fan while taking the reading in the mine, or make due allowance for the effect of the ventilating pressure to increase or decrease the aneroid reading, according as the fan is blowing or exhausting.

Under normal atmospheric conditions (temp. 60 deg. F., bar. 30 in.) 1 in. of barometric pressure, at sea level, in the difference in the two aneroid readings, corresponds to a depth of 923 ft. At an elevation of 1,000 ft. above sea level, under the same atmospheric conditions, 1 in. of barometric pressure corresponds to a depth of 960 ft. From these data, the depth of a shaft may be estimated by a simple proportion.

QUESTION—*A dam 10 ft. wide and 6 ft. high is filled with water to the top; what is the pressure at the top of the first square foot?*

ANSWER—The reading of the question is a little ambiguous; but, assuming what is wanted is the unit pressure (lb. per sq.ft., or per sq.in.), at a point 5 ft. below the top of the dam, or the pressure due to a 5-ft. head of water, this is $5 \times 62.5 = 312.5$ lb. per sq.ft.; or $5 \times 0.434 = 2.17$ lb. per sq.in.

QUESTION—*State in detail what, in your opinion, should be done to reduce the number of accidents due to falls of roof, coal and mine cars.*

ANSWER—Strict rules and regulations should be made and enforced by suitable penalties, in order to reduce the number of accidents due to the fall of roof and coal. Close supervision of all working places, while the men are at work, and careful instructions given to each man in regard to the safest manner of performing his work are necessary. It is important to adopt a systematic form of timbering suited to the particular conditions in the mine, and keep an ample supply of props and cap-pieces needed in each place. Every miner should be instructed to carefully examine the roof and coal in his place before starting to do any work.

The same careful supervision, rules, regulations and instructions are needed to avoid accidents from the movement of cars. No car must be left standing in the mouth of a room, or at the face of a chamber driven to the rise, unless the car is securely blocked to prevent its running out on the main road. Likewise, no cars must be left standing on sidetracks without they are securely blocked. Where drivers are hauling coal from different districts, a careful schedule must be prepared to avoid danger of collisions. On all roads used for haulage, where men must travel, shelter or refuge holes must be provided, except where rooms are turned off the entry. These holes must be kept free from all obstruction and should be whitewashed and not more than 20 yd. apart.

People's Right to Coal Paramount To Quarrels of Operators And Miners, Says G. O. Smith

All the fact-finding has not discovered any simple cure-all. This explains the absence of a clean-cut program as the final pronouncement of the Coal Commission.

The mine workers' method of giving a trouncing to their employers is, in fact, giving a clubbing to the public.

The practical problem we face is to find a substitute for force.

The Commission might well have hesitated to wholly abandon the idea of compulsory arbitration as a legal defense against those who declare industrial war against the whole people.

Compulsory arbitration and the coal industry as a public utility were discussed by George Otis Smith, former U. S. Coal Commissioner, in an address reviewing the recommendations of that defunct body, before the New York City Academy of Political Science on Nov. 20. He said that if the economic fact that coal mining is an indispensable service can be justly disputed or the legal right of the public to protect itself can reasonably be denied, coal is not a national issue and Congress might as well devote its thought to asparagus growing. Arbitration must be made compulsory, he said, if either party in the coal industry is unmoved by the moral pressure implicit in their joint obligation to furnish the public with coal.

"Plainly the Coal Commission needs an interpreter, yet no individual, however close he may have been to the now defunct Commission, can claim any exclusive warrant as authoritative interpreter; the field of constructive criticism to seek 'a wise and efficient policy' for the coal industry is open to all.

"The basic finding of the Commission was its statement of the economic fact that the mining of coal is a business clothed with a public interest, and this but repeats the underlying thought of Congress in providing for fact finding as a preliminary to legislation.

"The continued play of the spotlight has brought out many details," Dr. Smith said, "but all the fact finding has not discovered any simple cure-all. This explains the absence of a clean-cut program as the final pronouncement of the Coal Commission." The finding is: one of divided responsibility for things as they are and therefore of distributed obligation to make things different.

"The Commission's unequivocal declaration of belief that the union has been potent in bettering the workers' condition but that it can win public approval only as it in turn 'accepts in practice the principle that the public interest is superior to that of any monopolistic group, whether employers or employees,'" Dr. Smith says, "might have been condensed into the blunt statement that the union is needed to protect the miner, and the non-union fields are equally needed to protect the public. But this competition by the non-union fields, while affording the consumer a large measure of protection as to both price and supply, has cost dearly in other ways, especially in promoting overdevelopment and all the evil consequences that flow from it."

The Commission's recommendations, he said, are all well supported by findings of fact, yet "each and all of these reforms will fail to stabilize the industry and better the conditions for all concerned if periodic suspensions of mining are to continue.

"The people's right to a supply of coal at reasonable prices should be equally enforceable against a combination of operators raising the price or a combination of miners shutting down the mines. We have already outlawed combinations of capital attempting restraint of trade or even control of price; a country-wide combination of labor with the declared purpose of enforcing its own decrees by creating public distress would seem even less justified. When its half million or so members—a sixth of whom do not care to be American citizens—direct their united efforts against the whole people, the militant spirit of the mine workers' union takes on the ugly aspect of civil revolt.

"The open threat of tying up the commerce of a nation and shutting down its industries, the menace of economic chaos, is neither a just nor a legal method of obtaining higher wages for one class of workers in half a dozen states. Surely, the economic rights of the whole body of American workmen are greater than the rights of a small fraction of that body. The mine workers' method of giving a trouncing to their employers is in fact giving a clubbing to the public. This dangerous weapon, whether we term it strike or economic force, is one that does violence to the principles of popular government.

"The Commission interprets the public attitude as seeking from the union 'satisfactory guarantees of a fair and orderly adjustment of controversies in other ways than by the exercise of economic force,' and the practical problem we face is to find a substitute for force. The Commission has recommended voluntary arbitration for settling disputes and has also urged the fundamentally constructive method of building up the day-to-day relations between employees and employer, as well as the method of continuous investigation and timely publicity, yet full success of governmental action of this type, as the Commission realizes, would depend upon the recognition by operators and workers alike of the 'finality of the public insistence on continuous operation.'

ABUSE OF MONOPOLY POWER FORCES ISSUE

"If, however, either party to the controversy is unmoved by this 'irresistible moral pressure implicit in their joint obligation to furnish the public with coal,' it becomes all too obvious that arbitration must be compulsory. The outright rejection by the United Mine Workers at Atlantic City of any arbitration was most disheartening to many who wished the union well. Such use of monopoly power at once forces the issue, and the public's right to its coal supply demands protection from the strike. With that experience so fresh in mind and the threat of a bituminous strike next spring already heard, the Commission might well have hesitated to wholly abandon the idea of compulsory arbitration as the legal defense against those who declare industrial war against the whole people. Some of us believed that in default of a voluntary agreement compulsory arbitration would have afforded a more equitable adjustment of the recent anthracite controversy than the terms finally agreed upon. In the bituminous industry, however, compulsory arbitration of a wage-scale structure, to be fully successful as an agency of economic welfare, would need to have its awards enforceable throughout all coal fields, whether organized or unorganized.

"If coal mining, like transportation, is clothed with a public interest so great that its uninterrupted service requires public supervision of settlement of wage disputes, then those wage rates must be governed only by economic conditions, general and local, not by membership or non-membership in a union. The need of continuity of mine operation appears to involve mine worker and mine operator alike in a relation to the public quite different from that prevailing in less essential industries, and public safety and general welfare must soon force such legislation as will insure an uninterrupted supply of coal.

"The Coal Commission, moreover, sees other possibilities

for the mine workers' organization: in a transition from militancy to efficiency, the union thus becoming an active agency in improving the individual worker's status; in a program of education in mine safety, where joint action of operator and miner alone can fully protect their common interest; in a drive for Americanization and better citizenship, with the improvement of local living conditions; and above all, in building up the general realization that coal mining at its best is a co-operative enterprise that must be successful if it is to yield wages and profits. This common interest in continuous and successful operation is being stimulated in the British coal mines by the present adjustment of wages to results.

"Any turn-about-face in the policy and tactics of the union leaders, however, cannot be expected unless a similar reversal is made in the attitude of many of the operators—the employee in his period of dominance has copied all too much the earlier practices of the employer. Operators, like mine workers, have refused to arbitrate, and arrogance and tyranny were not invented by labor leaders.

"Throughout the investigation it was evident that everyone in the long line from householder to coal miner wishes someone else reformed and even regulated by law if need be. In fixing the place where something should be done the zeal appears to increase directly as the square of the distance of that place from home, and the average citizen's appraisal of the value of the work of the U. S. Coal Commission is likely to be affected by the direction in which its recommendations are aimed. Recommendations that involve all concerned plainly cannot be expected to win general acceptance."

Anthracite Operators Oppose Rate Cut Except on Steam Sizes

The hearings being conducted by the Interstate Commerce Commission on the question of a proposal for reduction of freight rates on anthracite coal was resumed at Philadelphia on Nov. 13. W. J. Thompson, secretary of the Anthracite Coal Operators' Association, chief witness for the day, said the operators are opposed to any reduction in freight rates on domestic sizes. If there is to be any reduction in freight rates, he said, it should be applied only to steam sizes, which are the only grades competing with bituminous coal. His reasons for advocating such reduction, he said, were predicated on the fact that one could not be produced without the other and that the domestic coals were consumed so much more rapidly than the steam coals accumulated rapidly and became a glut on the market. With a cut in freight rates on steam sizes, he said, the latter would move more freely to New England industries and elsewhere where soft coal is now used.

H. A. Taylor, general solicitor of the Erie R.R., for the carriers said that since the commission's last order to reduce rates the railroads, except for a brief period in 1923, had failed to yield the expected percentage of return on their property.

Harlan County Operators Decline To Meet Union Officials

"The United Mine Workers are trying to gain a little publicity or else stir up trouble, with their invitation to Harlan County operators to meet their officials. We will not meet them," declared R. C. Tway, head of the Tway Coal Co., of Louisville, Ky., and president of the Harlan County Coal Operators' Association, after he had received an invitation Nov. 11 asking the operators to meet union leaders at Harlan, Ky., Nov. 26, "for the purpose of negotiating a joint wage agreement for Harlan County." The invitation of the miners was signed by William Turnbaker, president, and E. L. Reed, secretary of the Southeast Kentucky-Tennessee union district. These officials said they "represented the miners of Harlan County." The operators point out that Harlan County is not unionized and they will not recognize the union as representing the miners there.

Nation's Lawmakers Await Pinchot Conference of State Executives

See Possible Influence on Coal Legislation—
Determination to Keep Up Non-Union
Wages Significant—Expect Demand for Laws

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

On Capitol Hill, where many lawmakers now are at their desks in preparation for the opening of Congress Dec. 3, those interested in coal are concerned principally in speculating on the possible effect on legislation of Governor Pinchot's meeting of state executives. Among the coal specialists, however, much more significance is attached to the apparent determination of all non-union operators to maintain wage scales on a reasonable parity with those being paid in union mines. They see in this a general realization of the unsettling influence of ill-advised and sporadic wage reductions.

While a generally held opinion among Senators and Representatives is that Governor Pinchot is making all the political capital he can out of the coal situation, sight is not lost of the fact that the meeting of Governors may have great significance. Such a meeting commands full publicity. The public will be acquainted with the details of the sessions. The action that will be taken will be of a character likely to influence and stimulate public opinion. It is expected to add to the demand that coal legislation of some sort be enacted.

It is generally admitted that Mr. Pinchot has not risen in the public esteem since he began taking a hand in coal questions. The disappointment felt because of his failure to make good on his promise that there would be no increase in retail prices, legislators point out, does not mean that the public is satisfied with the action of those directly interested in the production and distribution of anthracite.

Despite the tendency to speak rather lightly of Governor Pinchot's activities, it is apparent that the lawmakers recognize his ability to keep the anthracite question to the fore. In addition, he is in a position to require the anthracite companies to make full and detailed explanations as to the necessity for increasing the price.

The action of the non-union operators in giving a new stability to their wage scales is interpreted by some as a justification for the present level of wages in the industry. It will be recalled that the returns to the Coal Commission showed that the non-union scale was but little below that being paid in union mines. It tends to substantiate the position of those who contend that the pushing of non-union wage scales up and down has constituted one of the principal causes for the instability of the bituminous-coal industry.

The fact that the non-union operators are acting in groups on this question is held by some to indicate that they have discovered what the Central Competitive Field operators learned long ago—that the adjustment of wages by individual operators without reference to the rate of pay in the field as a whole has a demoralizing effect. When one operator is not entirely certain as to the wage scale being paid by his neighbor, frequent changes in the rate, with their unsettling tendencies, result. It also is noted that the recent action shows that the men in immediate charge of the mine are having the deciding voice in wage matters rather than leaving this important question to absentee boards of directors.

In this connection attention is called to the fact that southern West Virginia and eastern Kentucky must not forget that they may not be permanently rid of the United Mine Workers. Operators in the Kanawha district and in southeastern Kentucky, fields that were formerly union and now are running on an open-shop basis, must realize, it is believed, that a reduction in their wage scales at this time would be the worst thing that could happen if they desire to maintain open-shop operation. Nothing would furnish a better talking point for the union sympathizers.

Scientists and Politicians Discuss Coal In Two-Day Session

Symposium on "The Price of Coal" Elicits
Broadside from Pinchot Against Anthracite
Operators—Warriner Defends Producers—
Union Organizer Lauds Governor

Governor Pinchot, of Pennsylvania, S. D. Warriner, for the operators, and Thomas Kennedy, for the miners, were the speakers at the principal meeting of the first day's session of a symposium by the National Academy of Political Science on "The Price of Coal," in Philadelphia on Nov. 16 and 17. Governor Pinchot launched a broadside against the anthracite operators, charging them with maintaining a "hard-boiled monopoly" whose prime interest in the public was that it should consume their coal at their prices. He charged that it was a matter of common belief that the monopoly extends from the operators through the wholesalers to the retail dealers, implied that there is a conspiracy to keep prices at a high level and demanded that they clean house or have the public do it for them.

After quoting margins of retail dealers in anthracite in the larger cities of the East, which in some cases vary from 90c. to \$5.25, the Governor asked, "Is there a city anywhere whose range of prices at all corresponds with the range of margin? Just how does it happen that the retail price got to be so uniform? Have several somebodies been talking things over, or do the operators ration the coal to the retailers and so prevent price-cutting?"

"Mining costs of the operators vary from \$4.25 to \$10.25 per ton. Yet sales prices are within a few cents of each other. Have any persons talked these prices over?"

Mr. Warriner, speaking before Governor Pinchot, defended the operators, saying that the anthracite-producing industry had not averaged over the past ten years a 5 per cent return on book value, stating that the book value is even less than the present market value of the anthracite properties as determined by the engineers appointed by the Coal Commission. He said that the Governor's proposal that the operators refuse to sell to retail dealers who charged the public more than they had a year ago was asking the operators to violate the law in restraint of trade. He charged that although the law of Pennsylvania fixed the tax of 1½ per cent on the selling price of anthracite at the mines, the Pennsylvania state officials had assessed the operators in excess of the actual sales realizations on the ground that they had not realized the full market value for their product. This, he asserted, was strange in view of the contention that prices were too high.

The recent settlement of the anthracite strike, to accomplish which Governor Pinchot gave the miners a 10 per cent increase in wages, came in for its share of discussion.

"If the recent settlement be in accordance with economic law imposing fair treatment for all concerned, the result should be satisfying and no explanation or justification required," Mr. Warriner said. "If, on the other hand, it represents a dislocation of economic law by a resort to expedience, then those who are responsible must bear the consequences, economic and otherwise. The public criticizes the entire industry for the occasional malpractices of a few and denies that industry freedom to co-operate for their correction."

Governor Pinchot vigorously defended his settlement of the hard-coal strike. "The wage increase I suggested," he said, "was just and necessary to provide a decent American standard of living, to match the going wages in similar industries, and to compensate in part, but only in part, for the extra hazards of an industry in which 20,000 men are hurt each year. The 10-per cent increase was fully warranted not only because a supply of anthracite even at a small increase of cost was infinitely better than no anthracite at all but also because the eight-hour day and the 10-per cent increase on their merits were completely justified. The anthracite workers deserved and should

have had both of them, wholly without reference to the threatened strike."

In a subsequent session Van. A. Bittner, International organizer for the United Mine Workers, took occasion to laud Mr. Pinchot and to say that for his stand on the hard-coal settlement, wholly aside from the wage increase, he deserved to stand with the greatest statesmen of the country. Alba B. Johnson, president of the Philadelphia Chamber of Commerce, presiding officer at the Saturday afternoon session, remarked that, speaking as a Vermonter, he noted that Pennsylvanians have had a way of making a political question of anthracite and of bungling it in the past as at present. The state sales tax he characterized as contrary to American institutions and concluded that the coal industry is where the railroads were thirty years ago, with public opinion forcing them in a way contrary to good public policy.

Thomas Kennedy told why the miners are opposed to arbitration. He laid this attitude to the results of the 1920 arbitration before the Thompson commission, appointed by President Wilson. He said that the award of that commission was contrary to the facts presented and contrary to what they—the miners—had been led to expect. Without saying so, he gave the impression that the union considered that it had been double-crossed. Coal miners' wages are not responsible for the price of coal, he asserted. The United Mine Workers will stand firm, he said, for two things: a good and increasingly better standard of living, and independence of action as a union.

REVIEWS COAL COMMISSION'S WAGE STUDIES

The first session on Friday morning was devoted largely to wages and earnings of anthracite mine workers. Miss Anne Bezanson reviewed the studies made for the Coal Commission, Horace B. Drury compared earnings and wages of coal-mine workers with men in other industries, and John H. Libby, economist for the Bituminous Operators Special Committee, led the discussion.

The afternoon session was opened by Francis Walker with a historical review of the anthracite industry, followed by papers on costs of distribution and production by John W. Adams and David Wing. O. P. Hood, of the Bureau of Mines, talked on storage of coal, and E. W. Parker, Stephens Howarth, of the Coal Consumers Association of Philadelphia, and Roderick Stephens participated in the general discussion. Mr. Stephens said that to conquer the root of the trouble, cessation of production at the mines must be eliminated. "When an adequate supply of coal is mined it will be available at low and fair prices."

Willard E. Hotchkiss and J. H. Willits led the Saturday morning session on Labor Relations in Coal Mining. Mr. Hotchkiss said that the management must accept leadership in industrial relations and asked whether the coal operators had made industrial relations a major matter in their industry. He questioned whether management had mastered the job and whether it really knows the situation. Professor Willits reviewed the recommendations of the Coal Commission on labor relations, and Rice Miller, president of the Illinois Coal Operators Association, read a paper on labor relations in the Illinois coal fields. Francis J. Drumm, president of the miners' union of Maryland, told why the miners have a union. F. G. Tryon read a paper on "The Effects of Competitive Conditions on Labor Relations in Coal Mining."

The world's present fuel resources were discussed by Dean Holbrook, who demonstrated that water power and oil can never supplant coal. Hugh Archbald discussed

Efficiency of Mine Management. J. B. Neale, L. W. Wallace, H. S. Person and Van Bittner discussed Mr. Archbald's paper.

In the evening session E. E. Hunt read a paper summarizing the recommendations of the Coal Commission, and William Draper Lewis, professor of law, University of Pennsylvania, spoke on "Coal Price Regulation and the Constitution." He recommended a coal commission in line with the proposition Governor Pinchot is expected to suggest at his meeting of Governors next week. The final speaker was Judge Wm. S. Kenyon, of Iowa, who recommended more careful consideration of the code for industrial relations that while Senator he had proposed as a result of his investigations of the West Virginia situation.

Proposed Commission Legislation Analyzed

Recommendations Call for National, State and Municipal Enactments, National Coal Association Summary Shows

In view of the possibility of coal legislation coming before Congress next month, the following analysis of the Coal Commission's proposals for legislation, prepared by the National Coal Association, is interesting. This summary divides the recommendations into three groups; those requiring national legislation, state legislation, and municipal legislation. Summary follows:

A. Those Requiring National Legislation.—There are several recommendations which would require legislation in the nature of the formation of a permanent Coal Commission. The specific recommendations in connection with this are:

"1 (a) That Congress provide for the continuing co-operative study of and action against the problem of unemployment.

"(b) A continuing co-operative study of the principal jobs and of the existing rate differentials by the general government.

"(c) Continuous investigation and publicity by the federal government of the basic facts upon which industrial relations depend.

"(d) Special compulsory investigation when the prospect of failure to renew an agreement is imminent—specifically an investigation under authority of the President of the United States." (This latter part might require additional legislation other than that providing for a permanent commission.)

"(e) Continuous, compulsory publicity of rates and rate changes in the non-union fields by the general government."

2. They recommend that a division of the Interstate Commerce Commission should be established so that:

"(a) The powers of the federal government over interstate commerce may be used by an effective agency with sufficient funds, experience and powers for such regulation and supervision as may be necessary. This agency to be charged with direct responsibility for such activities." (They suggest that a special Division of the Interstate Commerce Commission be established and that the reports now received by the Geological Survey and Bureau of Mines be put on a permanent and co-ordinated basis.)

"(b) That the Interstate Commerce Commission be given authority through supervision to grant or withhold transportation service.

"(c) The long-haul to be no longer encouraged by favoring rates.

"(d) To readjust rates to cause economic zoning.

"(e) That in the future in determining the rating of a mine for the purpose of car distribution consideration be given to the commercial ability of the mine to sell its production as well as to its physical capacity to produce—that the commercial factor should be given a controlling influence in future mine ratings." (This may require a change in the Transportation Act.)

(f) It is recommended that: "Legislation provide for regular accounting reports to be rendered by all companies whose product moves in interstate commerce," and further recommended "that the agency to which the reports are

rendered shall have the power to prescribe the form of accounts." It is also recommended "that equal compulsory publicity of union accounts be required.

"3. The licensing of all who ship, buy or sell in interstate commerce.

"4. That under federal supervision natural limitation of markets by adjustment of rates, division of territory and consolidation and pooling of mines should be permitted.

"5. That operators should be exempted from the Sherman law for the purpose of collective bargaining.

"6. That the leasing law should be amended so as to give the Secretary of the Interior full discretion to make his approval of the opening of a new coal mine on the public domain contingent on a showing before the Interstate Commerce Commission that such a mine would serve the public interest.

"7. Levy a graded tax on royalties and differential profits." (This might be accomplished by national legislation or by state legislation.)

B. State Legislation.—1. (a) Safety service organizations should be compulsory in connection with compensation insurance.

2. State legislatures should provide for committees to revise the mining codes.

3. "That the practice of discounting 'script' be made illegal."

C. Municipal Legislation.—That each community license retail dealers' organizations, organize co-operative associations and establish municipal fuel yards.

Company Blamed for Glen Rogers Disaster

Responsibility for the mine disaster at Glen Rogers, Wyoming County, W. Va., on Nov. 8, when twenty-seven miners lost their lives in an explosion of gas, has been placed upon the Raleigh-Wyoming Coal Co. by a coroner's jury, according to an announcement just made by R. M. Lambie, chief of the Department of Mines of West Virginia, who conducted the inquest. The jury's verdict attributed the disaster to "Disregard of the vital requirements of the mining law on the part of the company's representatives in allowing the use of a dangerous electric drill, not approved by the mining department."

The explosion is said to have resulted from a spark from the electric drill in use at the time of the explosion, the spark, according to the head of the mine department, flying from the arcing of the brushes on the commutator of the drill. It is said that the head of the department had accepted such a theory at his first visit after the accident and upon his first examination after the bodies of the victims had been recovered. The drill in question was sent to the Pittsburgh electric laboratory of the U. S. Bureau of Mines and was in evidence at the coroner's inquest.

In all there were nineteen witnesses, among whom were Robert Stockdale, Clarence Rohig and Robert Lilly, mine inspectors; Charles Forbes, superintendent of the New River mine at Cranberry, a volunteer rescuer; William Steen, mine inspector for the New River company, also in a rescuing party, and several employees of the Raleigh-Wyoming Company. Just what action may be taken further in the matter is being considered.

THE U. S. SUPREME COURT granted a writ of certiorari Nov. 19 to review the decision of the Tennessee Supreme Court by which John D. Flanagan lost a suit for alleged breach of contract against the Federal Coal Corporation. Flanagan contracted with the coal company early in 1920 for delivery of 200 carloads of Tracy City coal that autumn at \$9 per ton, f.o.b. mine. The company accepted 73 cars and rejected 127 cars. Flanagan alleged the refusal to accept the coal was due to falling prices. He sued for \$28,000. The coal company's defense was that Flanagan had not paid the Tennessee State license fixed for wholesalers or brokers in coal, and hence the contract was invalid. The lower courts sustained this defense and the State Supreme Court concurred. Flanagan contended that the coal was for interstate shipment and hence the state license law did not apply.

Pinchot Calls Governors in Parley To Curb Anthracite Prices

Warriner Replies Sharply on "Housecleaning"
—Roderick Stephens Scores Governor's Plot
to Saddle Increased Price on Retailer

Gifford Pinchot, Governor of Pennsylvania, has invited the governors of twenty-eight anthracite-consuming states either in person or by representative to meet him in Harrisburg on Nov. 26 for the purpose of discussing the hard-coal situation, at which time he will outline a definite plan for national legislation and for state action. At the same time the Governor sent a letter to Joseph J. Walsh, Secretary of Mines of Pennsylvania, directing him to make an investigation of the quality of coal shipped and to make weekly reports of examinations.

In his letter to the various Governors, Mr. Pinchot refers to the conferences he has had with the committee headed by S. D. Warriner, representing the anthracite operators, concerning retail prices for coal, the last of which was held on Nov. 9, at the conclusion of which Mr. Warriner in a statement said that the Governor suggested that they should agree not to sell coal to retail dealers charging more for coal than last year, in reply to which Mr. Warriner pointed out the legal difficulty in such action and that it was the operators' understanding Governor Pinchot would obtain further advice and send him a definite plan operative within the law.

In his letter to the state executives, under date of Nov. 13, the Governor says:

"Since the coal strike was settled in September, I have taken up the question of price in a series of conferences with the members of a committee of the operators. On Friday last, this committee finally declined to recommend to the coal industry that it should clean its own house of extortion, as I have been urging it to do.

"We do not have to prove the existence of abuses in the anthracite industry or of crying injustice to the consumer in extortionate prices. They are matters of common knowledge. It would have been merely the most elementary common sense for the committee of operators to take these evils in hand. Being the producers of the coal, they have the power to do so most effectively. They could, if they would, not only give the consumer a square deal but at the same time free their industry of the public condemnation which now rests upon it. They have declined to do so. Then we must turn elsewhere.

"Since the settlement of the coal strike an investigation of anthracite prices has been in progress at Harrisburg and has resulted in the outline of a definite plan for national legislation and for state action.

"About 90 per cent of the anthracite mined in Pennsylvania is burned in other states. Therefore, justice to the great body of anthracite consumers must be reached mainly by national action. Such action can be secured most certainly and effectively if the governors of the anthracite-using states will unite in support of a single specific program.

"I am prepared to submit a suggestion for such a program, and I am asking the governors of the anthracite-consuming states to meet, either in person or by representative, in the Governor's office at Harrisburg on Monday, Nov. 26, at 2:30 p.m., to consider this program, and, if it is found practicable, to agree upon a definite plan of legislation to be laid before Congress at the opening session.

"To the extent that the State of . . . consumes anthracite your people are as deeply concerned in securing justice for the consumer as the people of Pennsylvania. For that reason I hope that it will be possible for you to be present in person at Harrisburg on Nov. 26, or in any case to be officially represented. May I have the pleasure of your company at a very informal dinner on that day at 7 o'clock."

The letter was sent to the Governors of Connecticut, Rhode Island, Vermont, New York, Maine, New Hampshire,

New Jersey, Maryland, Delaware, Virginia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Minnesota, Missouri, Nebraska, North Carolina, North Dakota, South Carolina, Tennessee, Texas, Wisconsin, Alabama, Massachusetts and West Virginia.

Samuel D. Warriner, president of the Lehigh Coal & Navigation Co., chief spokesman for the anthracite operators' policy committee, on Nov. 14 sent a letter to Governor Pinchot, in which he said he viewed "with indignation" the Governor's statement of Nov. 9 that the operators had refused to recommend to the industry that it clean its own house of abuses known to exist.

The letter said the Governor suggested that the operators agree not to sell coal to retailers who charged higher prices than last year, but that the operators feared such a plan would be a violation of the criminal laws of the United States, as it would mean an attempt on the part of the producers to fix retail prices in more than 25,000 communities. The letter also pointed out that the Governor had been assuring the operators for four weeks that he would endeavor to obtain the opinion of the State Attorney General on the point and that the opinion had not yet been received.

Governor Pinchot is charged with conspiring to force retail dealers to carry the increased cost of anthracite, in an open letter made public Nov. 15 by Roderick Stephens, chairman of the governmental relations committee of the National Retail Coal Merchants' Association.

Mr. Stephens wrote Mr. Pinchot that he hoped he would be guided by established facts in the coal situation, "rather than by prejudice, preconceived notions, political calculations or carelessly assumed obligations." The letter added:

"We submit that the retail coal dealer may very properly be held to account for any unwarranted addition to the cost of coal, over and above a fair margin to cover his costs of doing business, and to provide a fair return for capital invested, but in no sense can he be held responsible for ultimate prices to the consumer, which necessarily are based, not only upon the retail dealer's margin, but also upon the cost at the mines plus cost of transportation from the mines to the dealers' yards.

Coal-Price Agreement to Protect Public Not Illegal, Pinchot Is Told

Producers of anthracite "can agree with each other to control prices for the benefit of the public without infringing on the common law," although they might be in danger of prosecution under the Sherman law if they agree to hold prices below a maximum, according to an opinion by state Attorney-General George W. Woodruff to Governor Pinchot made public, Nov. 17. The opinion added that "it is hard to find how they could be attacked unless the Federal Department of Justice were hostile to action in favor of the public interest."

"In my opinion," Attorney-General Woodruff said, "independent arrangements or promises, with or to the Governor by each operator separately, intended to hold prices at the mine and to the consumer within some maximum figures would not be a combination in restraint of trade or a conspiracy either under the common law or the Sherman law."

The opinion at the outset took up the common law rule, holding that this makes it criminal, "for two or more to combine to fix prices contrary to the public interest," the basis of which, the Attorney-General declared, "is not combination itself but the harming of the public welfare through the combination."

"Therefore," he said, "under the common law it is my opinion that a combination in effect and intent protecting the public interest by holding down the price of anthracite coal to the consumer would, as far as the common law is concerned, be the opposite of criminal."

A copy of the opinion has been sent to S. D. Warriner, spokesman for the Anthracite Operators Policy Committee, who has had several conferences with Mr. Pinchot at the Governor's request to work out a plan to keep prices this winter at the same level as those of last year.

Production and the Market

Weekly Review

Day by day buying of soft coal continues sufficiently strong to move the balance of the output not under contract, but there is no snap to the market. Better inquiry is reported from some sections and the decline in production during the past couple of weeks has enabled shippers to clean up much of the distress coal which was so prominent. Nothing has developed to indicate that consumers are looking forward any more distressfully to what might happen April 1 and the industry seems to have settled down to a state where minor changes are noticed.

Coal Age Index of soft-coal prices was 183 on Nov. 19, the same as on Nov. 5, after having gone up one point on Nov. 12. The average mine price last week was \$2.21.

PRODUCTION RECOVERS QUICKLY

Output of both anthracite and soft coal recovered quickly from the interruption of election day. During the week ended Nov. 10 the soft coal produced is fixed at 10,737,000 net tons by the Geological Survey, while the anthracite output is estimated to have been 1,967,000 net tons. Soft coal produced during October amounted to 49,171,000 net tons, an increase of 2,955,000 tons over September, while the cumulative production to the end of the tenth month stood at 462,647,000 tons. During the past six weeks the average daily production of soft coal has been around 1,800,000 net tons.

There is no activity in the Middle West markets. Low production kept lump from Illinois and Indiana on a level, but other sizes drag heavily. Screenings are forced, although prices are down to what appears to be the bottom. There is no rush for anything in most sections. Kentucky operators are beginning to discuss the April 1 situation, at which time one contract expires, while another contract has a year longer to run. Reports from Ohio indicate dullness, except where distress coal can be gotten at low figures. There is no hope for better business held out in the Pittsburgh

market, which continues in bad shape. In New England there is no perceptible increase in demand and consumers show the same indifference they have maintained for several months.

A better feeling exists in the anthracite industry. Although demand for stove and chestnut sizes exceeds the supply most shippers believe that the consumers' wants will be well in hand before Jan. 1 and that there will be plenty of all domestic coals to be had. Production during the week ended Nov. 10 was 594,000 tons greater than the previous week's total. October shipments amounted to 8,724,000 net tons, making cumulative output for the ten months of 1923, 79,998,000 net

	Week Ended Nov. 12	Season to Nov. 12
Cargo	864,870	27,400,046
Fuel	45,655	1,479,018
Totals	910,525	28,879,064

tons, exceeding the production for each of the nine preceding years except 1917 and 1918, when the war stimulated mining.

With but two or three weeks remaining in the present Lake season, the total shipments of soft coal for 1923 are estimated to be but 825,375 net tons less than the 1918 shipments, the year of record movement. Up to

Estimates of Production

(Net Tons)

(a) Subject to revision. (b) Revised from last report.

Nov. 11 the shipments of anthracite through Buffalo and Erie amounted to 3,063,674 net tons.

Increased activity is reported in the export market, Italy figuring heavily in the news as well as increased demand from South America. Dumpings at Hampton Roads during the week ended Nov. 15 for all accounts amounted to 290,492 net tons, an increase of 64,865 tons over the previous week.

Midwest Market Still Low

Utter dullness prevails in the Midwest region in the trading of almost all coals. Illinois and Indiana lump are kept on a fairly even keel because of the low production, but all other sizes drag so heavily that southern Illinois egg, nut and mine-run circulars have frankly been cut. Egg drops 35c. to \$4, nut 70c. to \$3.65 and mine run 25c. to \$2.75, but even these prices do not move the coal. "No bills" in these sizes are still numerous. Screenings are moving only by force, although southern Illinois producers stick to their \$1.40@1.50 quotations. Central Illinois screenings are down to 70c. and Standard district remain at 50c.

Practically no coals from outside Illinois and Indiana are making any headway in the Midwest markets just now, although western Kentucky prices are alluring at \$2.75 for block coal and 60c. for screenings. Eastern smokeless continues to experience hard sledding around Chicago at a mine price of \$2.50 for mine-run with occasional shadings to \$2. Anthracite in moderate quantities moves steadily to regular trade, but there is no rush for anything. Scouts in the country south and west of Chicago bring in the news that although many retail yards have fair-sized stocks, the average retailer is doing little business and a small sudden demand for coal would exhaust the supply quickly.

Depression continues in the Carterville field and there has been added to the list a few more mines that have found it necessary to shut down. Even among the independents coal does not move. Cars are plentiful; service is a little slow, excepting on the M.P., on account of switching out "no bills." Similar conditions prevail in the DuQuoin and Mt. Olive fields. In the Standard field mines continue to suspend on account of no market.

There is no domestic business around St. Louis. The yards are full and everything is at a standstill. Similar

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

Index	1923			1922
	Nov. 19	Nov. 12	Nov. 5	Nov. 20
Index	183	184	183	343
Weighted average price	\$2.21	\$2.23	\$2.21	\$4.15

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

conditions are reported from the country. Locally wagon-load steam is easing up and while there was a little demand a week ago for carload steam, it too has fallen off.

Kentucky Is in Distress

The western Kentucky situation is far from satisfactory, and a number of operators are planning to close down, if there is not an improvement in prices or demand. It is asserted that a considerable tonnage is being moved at a direct loss. The low-cost strip mines which have been coming into the field rapidly are hurting the shaft mines to some extent. Car supply is a full 100 per cent or more on all divisions in western Kentucky.

Kentucky brokers and sales agents are having trouble in disposing of coal at any price just now, as retailers have stocks in hand. Industries are buying only cheap screenings. Mine-run is quite dull, as it cannot compete with screenings on price. Egg and lump are fair only. Block coal has been moving on a fair basis, considering the amount produced. Even screenings are running so low that some are stored at mines.

Northwest Talks Shortage

Shortage of acceptable sizes of hard coal is becoming more acute at Duluth and docks and dealers are urging the

use of substitutes. Three docks have definitely refused further orders for stove and nut, and others are taking care of only customers of long standing. Only three cargoes of hard coal reached Duluth last week in a total of thirty-nine cargoes and but two are reported on the way from lower lake ports in a total of nineteen en route.

It is estimated that Duluth and the Northwest would need about 300,000 or 400,000 more tons of hard coal to carry comfortably through the winter, and it seems impossible to bring this up before the close of navigation.

Lack of action in bituminous and fear of fires on the docks has caused the prices of screenings to sag. Hocking screenings are off 25c., and it is reported that a quiet shading on Youghiogheny and other grades is taking place.

Prices of soft coal at the Head-of-the-Lakes on lump, mine run, and screenings are: Kentucky, \$7.50, \$7 and \$4.25; Youghiogheny, \$6.50, \$5.55 and \$4; Hocking, \$6.25, \$5.25 and \$3.50; Splint, \$7, \$6 and \$4; Pocahontas, \$10, \$6.50 and \$5.50. Coke remains at \$10.50, with little demand as yet and briquets at \$10.

Around the Twin Cities trade is exceedingly slow and marked by much snowbirding. There the talk of anthracite shortage gets only a little attention, although it is admitted that the most desirable sizes probably will run a little short toward the end of the winter.

Warm weather continues to check the demand at Milwaukee, and there is little doing either by jobbers or retailers. A steady inflow of coal by lake, mainly bituminous, continues. Shipments to the interior by rail are below normal, however, and stocks on the docks are piling up. The present situation is bound to continue until the first cold-wave signal is hoisted.

Cargo receipts of coal for the first half of November aggregate 55,700 tons of anthracite and 315,556 tons of soft coal, making the season's cargo receipts since the opening of navigation to date 840,024 tons of the former and 2,913,257 tons of the latter. Car-ferry and rail receipts will augment these figures considerably.

West Shows Little Change

Little change in Western markets was shown during the past week except that in the Kansas City region screenings were dropped another 25c. down to \$2 in order to keep mine tracks sufficiently cleared so that coal can be loaded out to meet the slowly improving demand for domestic sizes. Mines in Kansas are averaging about 60 per cent running time nowadays.

In Colorado the market continues on its slow way with only a trifling improvement in domestic demand. Mines are running about 2½ days a week. Car supply and transportation generally are good, although a slide on the Moffatt line blocked tunnel No. 17 and shut off Routt County practically all last week.

Utah producers find business none too good. But the market seems a little spotted. Most operators are bogged down in screenings while one or two are a little behind in screenings orders. Some report better demand for nut sizes while others still suffer from middle sized "no-bills." Lump demand is fairly good, however. There have been no price changes. State figures just issued show that during the first nine months of 1923 total Utah production was 3,237,657 tons as compared with 3,462,690 tons in the same period last year. September production was 489,220 tons compared with 403,536 last year.

Ohio Markets Dull

Market conditions in nearly all parts of Ohio are dull. Buying is practically at a standstill except when distress coal can be picked up cheaply. In the Cincinnati territory, due to the weakness in low-volatile domestic coals, sales have been reported as low as \$4.75@\$5 for New River coal, though the standard companies handling Pocahontas deny they have changed their price from the \$6 circular. Although there are many idle mines in parts of Kentucky and West Virginia and there has been a reduction in output in the smokeless fields, tonnage coming to the market is in excess of demand. Industrial concerns in Ohio, Michigan and Indiana are not buying and are reported to have supplies

sufficient for from sixty to ninety days. Retail prices, as well as buying, have been settling down, and cuts were made in the price list last week.

Demand is quiet at Cleveland and the market is unable to absorb the coal available since shipping to the Lakes has eased up. More mines are closing and production in the eastern Ohio district shows a reduction. There is less slack to be had and quotations on this grade of coal for the past week show a slight advance.

At Columbus buying is slow, reserves are large and consumers are not disposed to increase their present accumulations unless they can pick up distress coals at low prices. Retail prices are showing the effects of the draggy market and are declining in sympathy with mine prices. Pocahontas and other smokeless coals are in best demand while some Kentucky coals are being sold for domestic purposes. There is a better feeling in the slack market.

There is no particular hope for real improvement in the Pittsburgh market unless there should be an interruption to free movement on the railroads. The market continues in poor condition and consumers seems to be convinced that nothing can prevent them from obtaining all the coal they may want at approximately the prices ruling in the past few months. Some distress coal is to be had, going sometimes at very low prices. There is a feeling of optimism among the operators in central Pennsylvania, who feel that a change for the better is about due in the bituminous-coal industry. Buffalo conditions continue dull and inactive. There is a little new strength reported for slack.

New England Consumers Indifferent

In New England on steam coal there has been no pronounced price movement the past week, although there have been slight indications of firmer prices. This is to be attributed largely to further curtailment of output and to the fact that small tonnages here and there of distress coal have been absorbed. There is no perceptible increase in demand, however, and consumers are maintaining the same indifferent attitude that has been characteristic now for some months. A few corporation buyers are quietly improving their opportunities of buying small lots that offer at attractive prices, but this affords practically the only market that can be seen anywhere at this writing.

On No. 1 Navy standard coals at Hampton Roads the price level advanced early in the week to \$4.75 per gross ton f.o.b. vessel, but two days later the market had again receded to \$4.35 and \$4.50. Second-grade coals are still being offered down to \$4.25, with liberal quantities of slack available at the lowest range of price yet named. On cars at Boston the market is practically unchanged at \$5 per gross ton, and almost none is sold except under pressure.

There is no change in the situation all-rail. Even the producers of quality grades find it extremely difficult to keep mines in operation and unless there is marked improvement in the next few weeks there will be more and more instances of complete shut-down.

Tidewater Market Shows Strength

The tidewater market at New York shows more strength, due to a cleaning up of most of the distress coal and lower shipments from the mines. Spot buying is not active and producers do not look for any great improvement soon,

although some houses report an increase in inquiries. The general situation at Philadelphia shows little if any improvement. Some houses claim to be making better shipments both on contracts and spot orders. Consumers continue to be conservative in their purchases and are slow to replace their consumed coals. Baltimore market conditions are not encouraging. As in other sections of the seaboard buying is dull and there is practically no activity.

Conditions in West Virginia have been affected by the strike on the Virginian Ry. and production of smokeless coal has been curtailed somewhat. There is an almost utter lack of demand for steam coal in the Birmingham field. Few orders are being received for spot coals and buyers are manifesting little interest. Bunker business is very dull, and unseasonable weather has slowed up domestic demand. The soft-coal market at Toronto, although somewhat improved, is by no means brisk.

Favorite Anthracite Sizes in Demand

Stove and chestnut sizes of anthracite are still in heavy demand by both dealers and consumers. There is considerable easiness in both egg and pea, as well as the steam coals, some retail dealers in the New York territory advertising in the daily papers that they have plenty of egg coal for sale. However, the chief call seems to be for stove and chestnut sizes. Improvement is looked for by most shippers as soon as lake shipments end and most dealers expect that there will be plenty of coal available before the first of the year. The steam sizes continue to increase in volume and are being stored in large quantities by those producers who have storage facilities. Baltimore dealers are short of coal, but there is no real emergency existing. Retail dealers in Toronto are receiving many orders for hard coal and supplies are fairly regular.

Production of beehive coke for the week ended Nov. 10 is estimated by the Geological Survey to have been 256,000 net tons, a decline of 10,000 tons from the previous week. The production of byproduct coke in October is reported at 3,099,000 net tons and of beehive coke at 1,290,000 tons, as compared with 3,112,000 tons of byproduct coke and 1,373,000 tons of beehive coke in September.

THE FIRST STEPS of the Reading Company to comply with the decree of the U. S. District Court in divorcing its coal business from its railroad business was taken last week, when an application for approval of a merger of all the railroad corporations of the company was filed with the Public Service Commission at Harrisburg. The Reading Company, as the holding company, controls the Philadelphia & Reading Railway Co. and twelve other underlying companies. The merged companies will be known as the Reading Company, and the commission will hear the application Dec. 5. The company contemplates forming another holding company for the coal and iron business, independent of the railway company.

Foreign Market And Export News

Foreign Demand for British Coal Heavy; Welsh Miners' Wages Cut

Quotations for the various grades of British coal for the week ended Nov. 17 show no change from the previous week while output, according to a cable to *Coal Age*, declined 80,000 tons during the week ended Nov. 3, when compared with the previous week's production, the figures showing a tonnage of 5,595,000 tons as against 5,675,000 tons during the week ended Oct. 27.

Conditions in the Welsh market remain very unsettled, though to some extent influenced by substantial contract sales over next year and a fairly heavy business awaiting early execution. The steam coal section shows a better undertone for backward loading, but for prompt positions conditions are unsettled and supplies are excessive.

Demands are heavy from France, Italy and Germany, while the South American business is brisk. Prices are varying widely because some operators are offering concessions to effect immediate clearances.

The Welsh miners' wages are reduced from Nov. 1 from 41.47 per cent over the standard of 1915 to 28.66 per cent, which is only 0.66 per cent above the minimum. It was a severe shock to the Welsh miners, and has greatly stimulated the demand of the extremists for the termination of the existing wages agreement.

The Newcastle market remains about the same. The intrinsic position is sound and buying and selling for current and forward delivery is active. Business with Europe is steady, especially from France, Italy and Scandinavia. The German situation is obscure. The Norwegian State Railways has taken 25,000 tons of steams at prices from 25s. 4½d. to 25s. 11d. f.o.b.

French Coal Market

No appreciable change is noticed in the French coal market. Demand for domestic and industrial coals is easy, owing to weather conditions, and dullness in business. It is believed that a change in prices will result due to the

increase in wages granted the miners. The market is taking much British coal, imports of industrial coals being heavy, while only sufficient British house coal to meet immediate needs is being called for.

Retail dealers have prepared a schedule of so-called "popular" coals as asked for by the authorities and are ready to dispose of them at about 200 fr. per ton, but the Paris Prefecture would like to have direct supervision of the sales to the public. This matter is now under discussion.

During the ten days ending Oct. 20 the Office des Houilleres Sinistrees supplied France and Luxemburg with 30,000 tons of coal; 61,100 tons of coke, and 4,900 tons of lignite, a total of 96,800 tons, as compared with 103,200 tons supplied during the preceding ten days.

France secured from the Ruhr during the first nine months of this year 1,091,290 tons of coal, 1,231,180 tons of coke and 78,160 tons of briquets, this representing a shortage in Germany's obligations to the Allies of between 12,000,000 and 13,000,000 tons, according to the stipulations of the Versailles treaty.

Great Britain Coal Exports

Great Britain exported 59,472,942 tons of coal in the first nine months of this year, according to the Bankers Trust Co. of New York. This was 13,996,369 tons greater than the exports during the corresponding period of 1922, and exceeded by 4,955,154 tons the exports in the same months of 1913. During the first nine months of this year France received 14,117,000 tons of coal from Great Britain; Germany, 11,604,000 tons and Italy 5,760,000 tons. Exports of coal to South American countries increased by more than 500,000 tons during that period when compared with 1922, but were below the tonnage exported to South America in 1913, 3,084,749 tons having been shipped, as against 2,506,113 tons in 1922, and 5,196,835 tons in 1913.

Hampton Roads Market Stronger

Conditions at Hampton Roads were strengthened last week as a result of the engineers' strike on the Virginian Railway, and the consequent depletion of supplies at the piers of that road at Sewalls Point. Shippers, however, reported buying to be unchanged.

With other roads rushing coal to tide-water to obviate any shortage, the Sewalls Point piers were operating on regular schedule but under some difficulties. Coastwise business was slowly improving, while bunker trade held its own. Foreign business was slower.

Domestic business was on the up-grade, with prices remaining firm. The tone of the market was somewhat stronger than recently and prices were higher.

News Items From Field and Trade

ALABAMA

The Thomas-Weller Coal Mining Co. has entered into an agreement with the trustee of the bankrupt Montevallo Mining Co. for the operation of the Aldrich mines, which were closed down several weeks ago by order of the court. The new operators contracted with the state for the employment of 150 convicts on free labor basis and expected to resume the production of coal about Nov. 15. Montevallo coal is a high-grade domestic fuel.

Explosion of a gas pocket in the mines of the Moffat Coal Co., at Moffat Spur, Bibb County, Nov. 12, resulted in the death of one negro miner and the injury of eight white miners and one negro, some seriously. The explosion was a local one and only those men near by were affected. There were about 150 men in the workings at the time of the accident.

The Hercules Coal Mining Co., capital \$2,000, has filed articles of incorporation in Jefferson County. The incorporators are W. T. Simmons, J. J. Lee and F. G. Moore.

ILLINOIS

Nokomis Coal Co. mine No. 10 set a new hoisting record for central Illinois mines on Nov. 6 when 5,846 tons were hoisted in eight hours.

R. B. Miller, state forester of Illinois, has estimated that twenty million feet of timber is used each year in the coal mines of Illinois, which is one fourth cubic foot for every ton of coal produced.

What is said to be a new world's record for speed in sinking a coal-mine shaft was set at Mason, Nov. 12, when the Illinois Coal Corporation struck coal at a depth of 730 ft. Work on the shaft started on April 23 and it was driven most of the way through solid rock by three shifts working twenty-four hours a day, seven days a week.

Suit for \$100,000 damages against the Missouri-Illinois Railroad Co. has been filed in federal court in East St. Louis by George A. Wilson, coal mine operator of Chester, who alleges that the railroad company has "illegally obstructed the mining of coal on property owned by him for the last five years" in that it has maintained a nearby water reservoir. The Illinois authorities will not permit him to operate his property because this pond adjacent constitutes a hazard to mining.

P. H. Sauter, of St. Louis, Mo., in filing suit in the federal court at East St. Louis, Ill., for a receiver for the Kolb Coal Co. stated that certain financial interests in New York and Philadelphia had obtained possession of assets of the company worth \$1,400,000, with an expenditure of only \$100,000. He states that there are 12,000 shares of stock due him. Erwin G. Schaukegel, auditor for the company was appointed receiver but the receivership lasted but a brief time. The future of the company is much in doubt.

INDIANA

Judgment for \$21,236.89 has been entered in the Boone Circuit Court, Lebanon, in favor of Harry Booth, receiver for the Black Comet Coal Mining Co. of Indiana, against the Indianapolis Street Railway Co. on contract. The defendant appealed. The case involved the purchase and delivery of 6,042.2 tons of coal. The plaintiff asked judgment in the sum of \$25,000.

T. P. Tillman, of the Indiana board of tax commissioners, and H. B. Wenger, engineer for the board, have begun checking assessments on coal properties of Vigo County. It was said by Tillman that the work consisted of reaching an agreement with the coal operators and that the assessments would come before the tax board before figures would be available. Local boards of review last spring displayed a tendency to let the work of assessing coal properties fall to the state tax board, according to the board's representative.

By a vote of 60 to 9, coal miners in a mass meeting at Princeton, Ind., recently adopted a resolution requesting that a special convention of District 11, United Mine Workers of America, be called to consider

complaints that the legal department of the Indiana union organization has been lax in its work with compensation claims and other such duties for miners. Miners from more than 50 locals attended the meeting. It is said that if ten locals ratify the action of the meeting here, a special convention will be called to cost between \$35,000 and \$40,000.

IOWA

Nearly one million more tons of coal were mined in Madison County, the past year than in 1922. There are nineteen fair sized mines in the county and eight small ones. A total of 4,020,159 tons was produced by the 4,643 men engaged in this industry. One miner was killed for each 574,398 tons and one injured for each 18,873 tons. Coal is produced in nine townships of the county, Edwardsville, Collinsville and Oliver townships being the largest producers. Alton township is the smallest producer, a small mine operated in the yard of an industrial plant bringing up 1,520 tons of coal during the year. Electric power is used in all the mines excepting three. The majority of the mines worked from 150 to 212 days during 1923.

KANSAS

Southwestern Interstate Coal Operators' Association reports for the last four years give an idea of the extent to which business in this district has slumped. Lopping off odd figures, the reports for 1920 show a production of more than thirteen million tons; for 1921, eight and one-half million tons; for 1922, less than six million tons, and, at the present rate of production, the figure for 1923 will be under that for 1922.

KENTUCKY

With four locks and dams finished in the Ohio River this year, and four more to be finished next year, it is believed that by 1925 the Ohio River will have the long needed 9 ft. stage from Pittsburgh to Evansville, and that it will take only a year or two more to complete the deep-water stage to the Mississippi River, which will result in free movement of coal on the Ohio and increased transportation by water of general freight. River coal companies believe the day is coming back when coaling river steam boats will mean something to them.

The election of William H. Fields as Governor of Kentucky is supposed to mean the revival of the question of the coal tax in that state. Mr. Fields made his campaign upon the ground that this tax should apply.

MINNESOTA

W. W. Broughton, president of the Pittsburgh Coal Co. of Minnesota with offices at Minneapolis, has resigned his position and A. K. H. Roehl has been appointed in his place. Mr. Roehl has been with the company for twenty-five years.

Ray W. Thayer, district salesman of the Northwestern Fuel Co. at the Duluth office was drowned recently while hunting at Pelican Lake in northern Minnesota. Ice on the lake crushed Mr. Thayer's boat and he was caught beneath the ice. He leaves a wife and one child.

MISSOURI

Southwestern Interstate Coal Operators' Association, reporting for its members, who produce about 95 per cent of coal in Missouri, Kansas and Arkansas and about 40 per cent in Oklahoma, says that 722,303 tons was produced in September of this year as compared with 880,735 tons in the corresponding month of last year. Cumulative production for the first nine months of the year amounted to 5,650,149 tons as compared with 3,568,954 tons during the corresponding period of 1922. The 1922 tonnage representing only four months and six days' operation on account of the strike.

Gus Lester, 43 years old, employed at the Lester Coal Mine, near Moberly, Mo., was killed in October when he was caught under a large rock while at work in the shaft.

NEW YORK

W. S. Simms, formerly with the Cory Mann George Corporation, Ltd., New York and London, will hereafter represent the Ridge Hill Products Co., of Philadelphia, in New York City with offices at 50 Church street.

Joseph Kersten and Amand Andry, engineering representatives of the A. France-Focquet establishment at Lége, arrived in New York City Nov. 10 and expect to visit Pittsburgh, Scranton and other points for the purpose of interesting engineers in the Kheolaveur process.

The business conducted by Douglas Pugh, 44 Whitehall street, New York City, has been consolidated with that of the Lee Coal Co., Inc., at 17 Battery Place, and Mr. Pugh has become manager of bituminous sales with the latter company.

The Walter Engineering Corporation, 290 Broadway, New York, announces that C. L. Young has accepted the junior partnership of the firm. Mr. Young spent some time in the Winding Gulf District last summer making some special examinations for Chairman Hammond of the United States Coal Commission. The engineering firm are experts on financing, accounting valuation, income tax matters, transportation, marketing and all phases of mining operation.

J. P. Noonan will be the manager of the New York office opened by the Clark Coal & Coke Co., of Fairmont, Va. Mr. Noonan has been connected with the Farrell Fuel Co., the Koppers Company and the Carnegie Steel Co. The Clark Company, with several mines in the northern West Virginia field, produces about 650,000 tons annually, having mines near Clarksburg, at Erie, W. Va., and near Tunnelton.

George J. Mehan, sales manager of the Buffalo office of the Lake Erie Coal Co., has resigned and been succeeded by C. H. Crowder, who was assistant to him.

The Fuel Service Co., of New York City, formerly at 350 Madison Avenue, has moved to new and larger offices in the Whitehall Building, 17 Battery Place, Room 2643, and has new telephone numbers—Whitehall 8248-8249.

Charles F. Park, Jr., has been elected vice president of the Coal & Iron National Bank, New York City. He will be in charge of the bond department. Mr. Park was formerly a member of the firm of Hitt, Farwell & Park.

The Fair Price Coal Commission representing the state and New York City met for the first time on Nov. 14 and organized by electing Major General Charles Berry chairman. The other members are Health Commissioner Frank J. Monaghan, representing the city, and George J. Eitz, representing the coal dealers. Major General Berry was appointed by Governor Smith to represent the state. The committee announced that plans had been formulated for dividing the city into zones with a view to fixing fair zone prices for various kinds of fuel.

NORTH DAKOTA

Proposed increase in lignite freight charges in North Dakota will be vigorously opposed by lignite producers. The increase would apply on rates as far as Minneapolis. Lignite men see in the proposed change a move to protect coal interests of other districts, and claim that lignite has been cutting into the soft-coal business of other districts. The North Dakota Railroad Commission has suspended the proposed rates for four months, pending a hearing.

OHIO

Bids were opened Nov. 8 by the Board of Education of Columbus for furnishing and delivering 1,000 tons of nut, pea and slack to the Central High School as follows: Euga & Stinchcomb, \$2.91; Reliable Coal & Supply Co., \$2.98, and the J. C. McIntyre Coal Co., \$3. Contract will be awarded later.

The use of Ohio coal by citizens of the state is urged by Governor Donahey, who asserts that Ohio fuel is discriminated against. Unless something is done intense suffering will prevail in the Ohio coal fields this year, he declares. The state government uses only Ohio mined coal and the Governor urges city and county officials to follow the example thus set. Dealers also are asked to try to prevail upon their customers to use the Ohio product. The Governor said it is not a matter of charity but of justice. "The Ohio coal miner never has sought, nor does he seek now alms," he says. "Neither does he desire to become the object of public or private charity."

Oscar W. Gardner, for many years president of the Chesapeake & Virginia Coal Co., Lynchburg, Va., with offices at Cincinnati,

has sold his stock in the company and retired from the organization. He has been succeeded as president by Clinton DeWitt. W. W. Ruby has been made general sales manager.

Coal operators in Ohio are well pleased with the result of the election Nov. 6 as it applied to certain amendments to the constitution. One amendment, taking away from an employee the right to sue the employer after the award of the Industrial commission of workmen's compensation insurance is made, provides for additional compensation for employees where accidents and diseases result from failure to comply with specific requirements for the protection of lives, health and safety of employees, and provides a fund for the investigation and prevention of industrial accidents. This amendment was adopted by a heavy vote and will soon become a part of the organic law of the state. Operators of coal mines will now be relieved from the danger of being sued even after compensation for the injury has been made.

Jay C. Lathrop, Cincinnati district representative of the Conveyors Corporation of America, Chicago, has removed his office to 503 Neave Building.

PENNSYLVANIA

The Pocahontas-Sewanee Coal & Iron Co., of Pittsburgh, which started about a year ago to develop 2,000 acres of a 12,000-acre tract of virgin coal land in Tennessee, about sixteen miles from Dayton, has had to suspend operations on account of lack of funds to continue, after driving 1,000 ft. of rock tunnel to within 50 ft. of the coal. The company is now endeavoring to raise money to continue, having a seam of coal between 8 and 9 ft. thick.

Operators say that higher pay received by men employed in and about the anthracite mines, under the new wage contract is attracting a number of former residents from other sections of the state to the towns where they lived years ago. Several men who left the collieries to seek fortune elsewhere say they can do better in the coal regions than in the large cities, where, they say, the cost of living is higher than in the coal regions.

The unusual construction of the Scotch Valley Mine of the Beaver Valley Coal Co., near Bloomsburg, prevented entombment and possible death of fifty miners Oct. 16, when a large section of the roof of the main gangway caved in. The mine is constructed on a slope, with an opening at the foot of the mountain lower than the remainder of the mine, affording natural drainage. Natural ventilation also has been obtained through the digging of holes from the top of the mountain to the workings. Several of these holes have been dug at intervals toward the top of the mountain, and it was through these holes that the miners crawled to safety when their exit was cut off by the rock fall. Several hours' work failed to make any headway in clearing away the debris, as other rock fell almost as rapidly as portions of the first fall were removed, making the work extremely dangerous.

Eighteen properties in Throon were damaged by a subsidence of the surface over the workings of the Olyphant colliery of the Hudson Coal Co. recently. Danger of further settling is not past, owners of property in the vicinity of the cave fear, and occupants of homes in the affected region are prepared to vacate their residences at any moment that announcement of danger is made by coal company officials.

Officials of the United Mine Workers at Pottsville report they have abolished the last of the town locals and set up colliery locals in their place, in spite of persistent opposition. Former Representative Reiley, representing John L. Lewis, international president, brought legal proceedings against several locals and forced them to hand over their charters. They had been operating independently ever since the order to change from town to colliery locals was given out following the district convention. These locals have now given up their charters and are joining the colliery locals, thus ending one of the bitterest fights ever staged in the ranks of the union.

Directors of the Glen Alden Coal Co., have declared a dividend of \$250 a share, payable Dec. 20, to shareholders of record Dec. 1. Since its formation the company has declared two other dividends, one of \$1.50 a share in November, 1922, and one of \$2 a share last May.

The United Mine Workers at the tri-district convention held at Wilkes-Barre on Nov. 13 decided to send protests to Washington against the proposed consolidation of the New York Central, and the Central Railroad of New Jersey and the Philadelphia & Reading Ry. The miners assert that if the roads are merged the anthracite fields

will work only three days each week, because of a shortage of cars. Members of the board reported that the Pinchot agreement by which peace was declared for another two years in the anthracite field, is working out satisfactorily.

Another big colliery will be put into operation in the Hazleton district next spring, the Candelmas Coal Co. has announced, and its output will go south over the lines of the Jersey Central R.R. The announcement came soon after borehole tests south of the Old Silver Brook breaker, which showed two seams, one said to be almost 100 ft. thick and the other about 30 ft. thick.

A 300-acre tract of coal land near Pottsville has been obtained on a long-term lease by the newly organized Jordan Coal Co. The price of the lease is said to be \$50,000. The coal tract is on a mountainside only 150 yards from the Lehigh Valley R.R. The new company contemplates the erection of a \$200,000 breaker in the spring. P. R. Jordan, of Scranton, who has developed numerous mining tracts, has been elected president of the new company.

Officials and miners with their ladies numbering one thousand attended the sixth annual banquet of District 17, held in Pittsburgh, Nov. 10. The district always speaks of the event as the John I. Pratt banquet, for it is the state mine inspector who manages it. William H. Pratt, son of the inspector, acting as toastmaster. Addresses were made by Thomas S. Baker, president of the Carnegie Institute of Technology; Crawford Wilson, who came from the mines; P. T. Fagan, president of District No. 5 of the United Mine Workers, and Dean Holbrook, of Pennsylvania State College.

Coal companies recently incorporated at the State Department, Harrisburg, are: Park Hill Coal Co., of Scranton; capital \$30,000; Herbert L. Williams, 302 South Main Avenue, Scranton; purpose, mining and preparing for market and selling anthracite; incorporators, David Lloyd, Herbert L. Williams and John Allen, Jr., all of Scranton. The Big Bend Coal Mining Co., Philadelphia, capital, \$35,000; Howard E. Foulkrod, 5144 Keyser street, Philadelphia, treasurer; purpose, mining, buying and selling coal; incorporators, Howard E. Foulkrod, Charles B. Redgate, Philadelphia, and George C. McIntyre, Colwyn. Harvey C. Stineman Coal Co., South Fork; capital \$10,000; Harvey C. Stineman, Westmont, Johnstown, treasurer, and one of the incorporators, the others being J. C. Davies, Johnstown and L. G. Venn, New York City. The purpose of the company is owning, operating and developing coal lands.

The Orient plant of the American Coke Corporation was offered for sale Nov. 8, as advertised by the receivers. No bid was received, but all the supplies were purchased by the Hillman Coal & Coke Co., of Pittsburgh, which has a number of operations in the vicinity of Orient. J. H. Hillman, Jr., chairman of the board of the Hillman Company, holds a large mortgage on the Orient plant which he is foreclosing, and the plant will be sold Dec. 1 to the highest bidder at Uniontown, by the Sheriff of Fayette County.

Contests for election of delegates to the international convention of the United Mine Workers of America, to be held in Indianapolis next January, are expected to be lively in the hard-coal fields. These elections are to be held next month and the three anthracite districts are entitled to about 100 representatives, in addition to the district officers, board members and secretaries.

A dynamite explosion on the evening of Nov. 13 destroyed the tippie of the Goshen Coal Co., at Surveyor, Clearfield County, causing a loss of \$18,000. During the past four or five months there has been a reign of terror in the little town owing to the adoption of I. W. W. tactics by a certain element among the miners. The Goshen company operates an open-shop mine and normally employs 50 to 60 men. Since June only about half this number have been at work, the remainder contending for recognition of the union. A series of explosions have occurred from time to time. Once a store fell and only two weeks earlier two charges of dynamite were set off in front of the residence of mine Superintendent Langford. A determined effort is now being made to run down the perpetrators.

It is reported that Rinaldo Cappellini, of Scranton president of District No. 1, United Mine Workers is mentioned as a candidate for state Senator for the Twenty-first district, which is now represented by P. F. Joyce, of Pittston. Reports also have been current concerning the possibility of Thomas Kennedy, of Hazleton, president of the United Mine Workers, of District 7, run-

ning for Congress. This report is also left unverified.

The Lillibridge breaker, located at Blakely, was destroyed by fire on Nov. 13. The damage, according to the owners of the structure, will reach \$5,000. The breaker was built about eleven years ago by S. S. Spruks, who operated it successfully until three years ago, when it was sold to Levi Lillibridge and associates. When erected the structure was valued at \$13,500, but two weeks ago it was offered for sale at \$2,000.

Valuation of coal lands in the city of Scranton for purposes of tax assessment in 1924, has been fixed at \$800 per foot acre. The new figure represents an increase of \$480 over the present figure, which has stood for the past two or three years, or since counsel for the city and the coal companies agreed upon \$320 as a fair valuation on an 80-per cent basis. It is understood that the \$800 valuation set by the city officials is on a 100-per cent basis.

Shipments of anthracite during October, 1923, amounted to 6,564,526 gross tons as reported to the Anthracite Bureau of Information, Philadelphia. These figures are not comparable with the previous month of September on account of the suspension of mining during negotiations between operators and miners, operation not being resumed until Sept. 19. The average daily shipment in September after operation was resumed amounted to 219,490 gross tons, while the average daily shipment during October amounted to 262,581 tons, an increase of about 43,000 tons. Comparing last month's shipments with October, 1922, there is a decrease of only a little over 3,000 tons, but an increase of 691,743 tons when compared with October, 1921. Shipments by originating carriers were as follows:

	October 1923	Sept. 1923
Phila. & Reading.....	1,205,425	420,859
Lehigh Valley.....	1,174,768	372,997
Jersey Central.....	564,471	154,200
Del., Lack. & Western..	1,017,231	318,182
Delaware & Hudson....	861,705	298,775
Pennsylvania	576,345	196,839
Erie	707,076	251,277
N. Y., Ont. & Western..	174,707	61,229
Lehigh & New Eng.....	282,798	120,582
Totals	6,564,526	2,194,940

The semi-bituminous mines located at Dutch Mountain, Forkston Township, after being idle for the past twenty years have been reopened under the ownership of William Booth and Ralph Peters, both of Wyoming, Pa. New buildings have been constructed and the new owners plan to erect a breaker on the site within a short time. Construction of a railroad from the mines six miles to Mehoopany is now contemplated.

W. W. Inglis, president of the Glen Alden Coal Co. is this year heading the anthracite mines division in Scranton and Dunmore in the annual Community Chest drive.

The State Water and Power Resources Board is endeavoring through representatives of the anthracite coal companies to devise means of keeping the Schuylkill River at Port Carbon free from culm and coal dirt. Complaints about the condition of the river at that point have been filed with the board.

An opinion by J. W. Brown, Deputy Attorney General, just given to William B. McGrady, chief of the Bureau of Standard Weights and Measures, states that coal in Pennsylvania must be sold by weight, but that there is no law that compels a dealer to install scales. The inference of the Attorney General's department is that the local sealers of weights and measures must see to it that the dealers weigh their coal on public or other scales before delivery.

Patton, Cambria County, Local Union No. 842, United Mine Workers, at a meeting on Nov. 1 adopted a resolution requesting the Cambria County commissioners to lower the miners' occupation tax valuation from \$300 to \$200. The resolution stated that the miners' occupation tax is higher in Cambria County than in any of the neighboring counties and that working conditions of mining throughout the county are poor.

W. S. Ayres, consulting mining engineer, of Hazleton, who has been a member of the American Institute of Mining and Metallurgical Engineers since 1873, was unanimously elected by the board of directors at its recent meeting to the honor roll of senior members.

Over thirteen hundred miners attended the annual banquet of the Hazleton Mining Institute held at the Hotel Dupian, Hazleton, on Nov. 8. Dr. Charles Aubrey Eaton, of New York, was the speaker of the evening.

UTAH

The U. S. Land Office at Salt Lake City will offer for lease 1,120 acres of public coal land in Carbon County tributary to the north fork of Gordon Creek. The coal of this area is bituminous and is a high-grade domestic and steaming fuel. Lease for this tract will be at a Government royalty of 10c. per ton for coal mined, a minimum investment in mining operations of \$40,000 during the first three years of the lease, and a minimum production of 20,000 tons of coal a year beginning with the fourth year of the lease.

VIRGINIA

A charter has been issued to the Clinch River Coal Corporation, Colburn, with a capital stock of \$100,000, to mine and deal in coal and other minerals. Incorporators: William J. Jegen, president, North Glenside, Pa.; Mortimer B. Kelly, secretary, New York, and Jeremiah J. Kelly, New York.

The Clinchfield Coal Corporation has contracted for a complete Roberts & Schaefer steel tippie at its No. 52 mine at Dante.

E. M. Robinson has become local manager for the Eastern Coal & Export Co., Norfolk, to succeed C. L. Massei, resigned.

WEST VIRGINIA

The La-Go Pocahontas Coal Co. has just been organized with a view to operating on a fairly large scale in the Tug River field in McDowell County, the new enterprise being capitalized at \$100,000. The company will have its plant in the vicinity of Iaeger. Active in organizing this company were T. B. Lane, Carmie B. Lane, of Iaeger; C. L. Gaujot, of Glen Allen, and M. H. Leggett and A. F. Meyer of Cincinnati, Ohio.

When William Blizzard, president of sub district 2 of District 17, United Mine Workers, was placed on trial for the fourth time at Lewisburg on Nov. 12, charged with being an accessory to the murder of a Logan County deputy sheriff during the armed march of 1921, his counsel made a motion for a change of venue on the ground that Blizzard could not obtain a fair trial in Greenbrier County and at the same time asked for a continuance because of the illness of H. W. Houston, senior counsel in the case. The defense counsel submitted a large number of affidavits in support of the motion for a change of venue, stating that they had heard rumors of propaganda intended to prejudice the county against the defendant. It also was alleged that in view of the conviction of Howard Harrah, foreman of the jury which disagreed when Blizzard was tried last summer, and the conviction of G. C. Hickey, a defense witness on the charge of bribery, jurors would be afraid to vote "not guilty." The state in its answer replied that the petition dealt with an alleged situation which the defendants or those interested with them brought about and that they were thus endeavoring to take advantage of their own misdeeds. On Nov. 16 Judge Sharp denied the motion for a change of venue.

It is reported at Bluefield that the Pocahontas Fuel Co. had purchased the last thirty thousand acres of undeveloped coal of the original Pocahontas seam located in Tazewell County, Virginia and McDowell County, West Virginia, and known as the Faraday tract, owned by the heirs of the late H. C. Frick. It was reported the deal had been closed in New York and that \$500 per acre had been paid. The Faraday tract is the only undeveloped property of the original Pocahontas coal; not even the timber rights have been touched. In some places on the property the seam is over 10 ft. in thickness. Under certain provisions of the will of the late H. C. Frick, a certain sum of the money to be derived from the sale of this property was bequeathed to Princeton University, it was said.

The Federal Power Commission announced Oct. 30 that it had issued a preliminary permit to the West Virginia Power Co., of Charleston, for a power plant to be located about 5½ miles south of Hinton, with a transmission line about 22 miles in length, extending to Beckley.

A dividend will be paid before Jan. 1, 1924, by the Coal River Collieries Co., owned by the members of the Brotherhood of Locomotive Engineers, Warren S. Stone, president of the organization, announced at Huntington on Nov. 13, following a conference with officers of the concern. The amount of the dividend will be determined at a later date. The Coal River Collieries Co. was organized several years ago with a capital stock of \$2,000,000. It owns and operates extensive holdings in Boone County.

WISCONSIN

The Valley Coal & Dock Co., of Milwaukee, against which an involuntary petition of bankruptcy was filed in the Federal Court two months ago, has submitted a schedule of assets and liabilities. The liabilities total \$187,039, and the assets \$321,819.

The small steamer Wotan, which delivered a cargo of anthracite at DePere, a Green Bay port, is in the hands of the authorities pending inquiry as to the source and destination of a quantity of whiskey alleged to have been found on board.

The steamers Alex B. Uhrig and Jos. W. Simpson have been sold by the Milwaukee-Western Steamship Co., an auxiliary of the Milwaukee-Western Fuel Co., to the Reiss Steamship Co., a connection of the C. Reiss Coal Company of Sheboygan.

A voluntary petition in bankruptcy was filed in the Federal Court at Milwaukee Oct. 27 by the Standard Harlan Coal Co., a corporation engaged in wholesaling the product of Kentucky mines. Liabilities are listed at \$126,380 and assets at \$93,469.

WASHINGTON, D. C.

The Federal Trade Commission has announced that the hearing scheduled for Nov. 19 to take testimony in the complaints filed against Madeira-Hill & Co., of Philadelphia, and other wholesale coal dealers, has been postponed until Dec. 3. No reason was assigned for the postponement of the hearing, but it was understood that conflicting engagements for Nov. 19, between the commission and the respondents was responsible for delaying the hearing.

The National Retail Coal Merchant Association's headquarters have been established in the recently completed Transportation Building, in Washington, following removal from Philadelphia. Joseph E. O'Toole remains in charge as resident vice-president and Major Walter D. Rogers has assumed the duties of executive secretary. Major Rogers was a member of the staff of the Coal Commission during the life of that body, and previously had had wide experience in the retail phase of the coal industry.

Coal merchants of Washington soon will submit bids to Secretary of the Interior Work which officers of the National Retail Coal Merchants Association hope will lead to elimination of the Government Fuel Yard in the capital city. The dealers will bid only on delivery of coal to the government steam plants in the District of Columbia, without attempting to take over or interfere with contracts for purchase of coal at the mines by the government. The dealers expect to be able to establish by these bids that they can deliver coal to the government plants from various yards more cheaply than the government is now delivering in its own trucks from the central fuel yard.

Paul S. Black, who has been serving the War Minerals Relief Commissioner in a legal capacity, has been recalled to the service of the Bureau of Mines to undertake a study of state and federal coal-mining codes and workmen's compensation acts and laws dealing with safety in mining. This work is being undertaken in an effort to carry out one of the recommendations of the Harding Coal Commission. Dean Holbrook, of Pennsylvania State College, will co-operate with Mr. Black in this work.

Arthur P. Davis, past president of the American Society of Civil Engineers, who was summarily dismissed as Director of the Reclamation Service by Secretary Work, has been elected to honorary membership by the Washington Society of Engineers. This honor has been conferred on only four others. They are Commerce Secretary Hoover, Admiral H. T. Endicott, Admiral D. W. Taylor and Dr. F. H. Newell. Mr. Davis now is in England representing the Department of State on engineering matters coming before the Pecuniary Claims Commission.

Decisions of the lower federal courts by which the Diamond Fuel Co. was declared a bankrupt have been upheld by a decision rendered for the U. S. Supreme Court by Associate Justice Sanford. An involuntary bankruptcy petition was filed against the Diamond Fuel Co. by the Pittsburgh & West Virginia Coal Co. and two other coal companies. Before final action other creditors joined in the petition. The Canute Steamship Co. and others filed an intervening petition in opposition, claiming liens. They alleged the Pittsburgh & West Virginia Coal Co. was not a creditor of the fuel company, and hence that the petition had not had the necessary three creditors joined in the filing. The lower courts held, and the Supreme Court agreed, that intervention of other creditors validated the

petition under the bankruptcy laws and that it was unnecessary to pass on the standing of the Pittsburgh & West Virginia Co. The case had been appealed by the Canute Steamship Co. and associates.

CANADA

The capital stock of the Milnes Coal Co., Toronto, has been increased by Letters Patents from \$250,000 to \$500,000.

The Crow's Nest Coal Co. has declared a dividend of 1½ per cent payable Dec. 1 to shareholders of record Nov. 13, 1923.

The United Mine Workers local at No. 21 colliery at Birch Grove, near Glace Bay, and the Thorburn, Pictou County local have had their charters cancelled by the provisional officers of District 26, acting on instructions from International President Lewis due to the fact that neither of the two locals has paid its per capita tax into the International treasury for some months past. Officers of the Thorburn local have expressed their willingness to pay the back per capita taxes, to have their local restored to good standing. They have also extended the courtesy of the local to the provisional officers with a request that they pay a visit at an early date. The Thorburn local was informed that the provisional officers were not in a position to restore their charter, as President Lewis was the official who had the authority to do that. As a result of the revoking of the two charters, each and every member of the two locals must pay an initiation fee of \$10 before they can again become members in good standing.

The Mining Safety Device Co., of Bow-erston, Ohio, is furnishing part of the equipment for the new mine of the Dominion Coal Co., Ltd., at Glace Bay, N. S. They are installing Nolan automatic cagers at both top and bottom, Nolan automatic cushioned horn stops on the cages, and Nolan automatic retarders. All this material has been shipped and work is being rushed on the mine.

A comparison of the production of the different coal fields of the Province of British Columbia for the first ten months of 1923 compared with the same period last year shows that on Vancouver Island there has been a decrease of 166,005 tons; in the Nicola-Princeton Field a falling off of 35,343 tons; while in the Crow's Nest Pass there has been an increased output of 161,980 tons. The improvement indicated by the latter figures is accounted for by the fact that in 1922 there was a three-months strike in the Crow's Nest Pass while this year no labor trouble has interfered with the activity of the mines.

Frank Cherry, of Prince Albert, Saskatchewan, has filed a claim on coal lands near that city on the Little Red River, and has taken out a small trial shipment. The coal is said to be a fair grade of bituminous and improves in quality as distance is gained from the surface.

It is estimated that the coal production of Nova Scotia this year will amount to at least 6,200,000 tons. As the total production last year was 3,642,196 tons, the increase this year will be more than two and a half million tons. According to Hon. H. E. Armstrong, Premier and Minister of Mines, the collieries are in good condition and preparations are in progress for the opening of new mines.

JAPAN

The Government of Japan has conferred the second degree order of the Sacred Treasurer upon General Guy E. Tripp, chairman of the Board of the Westinghouse Electric & Mfg. Co. This is the highest decoration that can be awarded a civilian foreigner by the Japanese government. General Tripp is in Japan in connection with reconstruction work following the recent earthquake, and his decoration was in recognition of his activities in assisting the Japanese officials in rebuilding the devastated area.

Obituary

Thomas Thedford, former president of the New York Coal Exchange, died in his home in Allenhurst, N. J., Nov. 13 at the age of 82. He retired from his New York City coal business about fifteen years ago and moved to Allenhurst.

John Perry, 73 years old, one of the founders of the Central Coal & Coke Co. of Kansas City, died Nov. 7 at his home in Sandon, Chelmsford, England. For almost twenty-five years he had made his home in England, the place of his birth.

Publications Received

A new Department of Commerce publication to be known as the "Year Book," an annual review of the industrial developments of the country, having for its general purpose the presentation to business men of the country an analytical review of progress as a guide to trends of trade and economic forces, is now in course of preparation by Secretary Hoover. A feature of the book will be a chapter by F. R. Wadleigh, chief of the Department's Coal Division, dealing with the coal problem.

The Bituminous Operators' Special Committee has just issued for distribution a 32-page pamphlet entitled "Violence in the Coal Fields," embodying a series of news releases summarizing briefs filed with the U. S. Coal Commission by counsel for the Special Committee or co-operating organizations. The following is a list of subjects, by title, covered in the pamphlet: Brief of the General Policy of the United Mine Workers; Violence in Ohio; Union Activities in Northeastern Kentucky; Absentee Leadership Gives Advice (the Hermin Massacre); Stimulated Strikes in Central Pennsylvania; The Verdict of the Southwest (the War Against Labor-Saving Devices); Making the Public Pay Through Violence (the Campaign in Utah); Organized Intimidation in Alabama; The Unsuccessful Campaign in Somerset County; Kanawha (the Belgium of the Coal Fields); Periodic and Systematic Violence in West Virginia; Warlike Labor Monopoly in Indiana; Use of the War Chest in Georges Creek and Upper Potomac Coal Fields; Check-Off Abuses; Comparative Efficiency in Union and Non-Union Fields; The Company Town.

Traffic News

The Interstate Commerce Commission has decided that bituminous coal rates in carloads from mines on the Chicago & Alton and Wabash roads in the Springfield (Ill.) district, to St. Joseph, Mo., are unduly prejudicial to the extent that they exceed by more than 40c. a net ton the rates contemporaneously maintained by the carriers from the same points of origin to Kansas City.

The Interstate Commerce Commission has set Finance Docket 3131 for oral argument at 10:30 A.M., Dec. 29, before the full commission at Washington. This docket relates to the application of the Atlantic Coast Line and Louisville & Nashville R.R. for authority to acquire control, by lease, of the C. C. & O., C. C. & O. of South Carolina, and the Clinchfield Northern Ry. of Kentucky.

The defense of dock operators to the action brought by the Federal Trade Commission declares that the rate on coal from the docks to the Twin Cities of \$1.82 is at least 32c. too high and should be reduced to \$1.50. They assert that the high rate discriminates in favor of the Illinois all-rail operators.

Questions involved in the case of Burns Brothers, of New York, vs. the Pennsylvania Railroad Co., will be considered at an Interstate Commerce Commission hearing in New York Dec. 17. Examiner J. E. Smith will preside. On Dec. 20 Examiner McChord will hear at Big Stone Gap, Va., a discussion of the claims of the United Collieries, Inc., against the Southern Railway Co.

All records for shipment of coal over the New York Central R.R. from Ashtabula, Ohio, have been broken this year. To and including Nov. 8, 60,330 carloads, or 3,318,189 tons, of coal had been transferred from car to vessel over the New York Central docks at Ashtabula, as compared with 45,958 cars, or 2,099,001 tons, on the corresponding date in 1916, hitherto the record. The 1923 coal was forwarded in 800 vessels to Northwestern ports. This represents an increase of 58 per cent over the previous record. Eighty-five per cent of the total coal shipments for the year had been forwarded on Nov. 8, 1916. If the same proportion holds good this year the total for 1923 will be 3,903,700 tons. The grand total of coal shipments from all lake ports to Nov. 8 was 27,412,901 tons, New York Central shipments from Ashtabula amounting to 11.6 per cent of the total.

The Louisville & Nashville R.R. Co. has taken exception to the tentative report in the matter of divisions of rate with the Cumberland & Manchester R.R. and requests that oral argument be allowed. The

L. & N. contends that the examiner erred in assuming that because it has been the custom in the divisions of rates on coal to allow the Northern lines certain proportions under circumstances and conditions differing entirely from those involved in this case, the custom should warrant a dismissal of the present case. It is contended that the examiner was wrong in his failure to find that the present proportions are unjust. It also is argued that the examiner erred in ignoring the fact that the divisions of rates on coal from Cumberland and Manchester stations to all Southern destinations are involved in the proceeding.

Two indictments, each containing 100 counts, were returned against the Buffalo, Rochester & Pittsburgh Railway Co. and the Buffalo & Pittsburgh Coal & Iron Co. by a federal Grand Jury at Buffalo, N. Y., Nov. 12. The indictments charge that the two companies entered into an agreement when the coal mining suspension of last year was impending, whereby coal was to be held in cars of the railway company for its own use and for the coal company's customers. The indictments also allege that the railway agreed not to collect demurrage charges, that discrimination was shown against other coal shippers and that concessions were granted in freight rates previous to the actual mining suspension. The last charge is that the railway failed to collect reconignment charges on shipments made after the period of the emergency was ended.

In the case of the Victor American Fuel Co., the Bear River Coal Co. and the Routt Pinnacle Coal Co. vs. the Denver & Salt Lake R.R. Co., the Moffat Coal Co. and the Colorado-Utah Coal Co., two novel questions are presented. One is: Can a shipper, in a complaint case before the Interstate Commerce Commission, join as defendants, with the carriers complained of and obtain against defendant shippers, as well as against the defendant carrier, an order for reparation or other relief? The other question is: Can the complainant shipper in such a case obtain reparation in kind, that is, in cars, instead of in money, to an amount measured by the actual damage suffered? In reply to the first question, the attorneys for the Moffat Coal Co. contend that "neither the Commission itself nor any party complaining to the commission, in any of the almost numberless cases which have arisen and have been dealt with in that long period, has attempted to join as defendant any party other than a common carrier subject to the Interstate Commerce Act." They also contend that the commission is without power to award reparation in cars. One of the requests of the complainants was for an order requiring the carrier in future periods of car shortage to make up to the complainant coal companies the deficiency in cars resulting from the past acts complained of and that such shortage in car distribution to the complainants' mines be made up at approximately the same daily rate at which the shortage accrued from Aug. 1, 1922.

Due almost entirely to reductions in freight rates, made both voluntarily and by order of the Interstate Commerce Commission, the freight bill of the people of this country was approximately \$431,000,000 less during the first eight months this year than it would have been if the rates existing during the corresponding period in 1921 had remained in effect. Compared with the rates in effect during the first eight months of 1922, the freight bill this year represents a reduction of approximately \$282,750,000 due to the voluntary reduction on agricultural products that became effective on Jan. 1, 1922, to the general rate reduction of 10 per cent effective on July 1, 1922, and to a number of individual readjustments in freight rates. These estimates, which are made by the Bureau of Railway Economics from reports filed by the carriers with the Interstate Commerce Commission, are based on the freight traffic transported by the carriers from Jan. 1 this year to Sept. 1, which has been the heaviest in history.

Interstate Commerce Commission Examiner Paul Carter in a tentative report to the commission, states that there is no evidence that the rates on bituminous coal from mines adjacent to the line of the Chicago, Burlington & Quincy R.R. in the vicinity of Canton, Ill., were discriminatory against interstate commerce between Jan. 11, 1921, and April 18, 1922. The complaint in this case was brought by the International Harvester Co. and the Canton Gas & Electric Co. The complaint raised the question of the jurisdiction of the Interstate Commerce Commission. He recommends, however, that the commission modify its former order to the extent of permitting these rates to be reduced to a 60c. basis for the period mentioned.

The rules, regulations and practices relating to the weighing and reweighing

of anthracite and bituminous coal and coke are not unreasonable, the Interstate Commerce Commission has ruled in a formal opinion in the case brought by the National Retail Coal Merchants' Association against the sixteen railroad companies operating in trunk line and New England territories. The association asked the commission to prescribe rules which would provide that a shipper may be required to pay freight only upon the actual, accurate weight of the shipment; that he is entitled to a reweight upon request; and is entitled to show by reweighing, or by some other means, that the weight sought to be used is erroneous; that where a shipper requests the reweight of a shipment, and the reweighing shows error beyond the limit of tolerance fixed, (a) no charge shall be made for the reweighing service; and (b) freight charges shall be collected on the corrected weight, only, and that the total tolerance, for all purposes, should not exceed 1 per cent of the original weight, minimum 500 lb. In dismissing the complaint, the commission rather rebuked the association for not having introduced evidence to support its contentions. "As a basis for the entry of an order directing changes in the tariffs and practices of carriers," says the opinion, "we must have some reasonable ground upon which we can be satisfied that the law is being violated." The commission picks up language quoted in a previous opinion as follows: "The case seems to have been thrown together as if the commission needed only to have the opportunity presented to it in order to take favorable action. But we are administering this law upon no such basis. We are authorized under the act to order a reduction in rates only when it is made to appear that they are unjust, or unreasonable, or unjustly discriminatory, or unduly preferential. Complainants must therefore prove the issues that they raise by competent testimony or make out a prima facie case sufficiently clear and strong to require the commission in the public interest to enter upon an investigation of its own to ascertain the merits of the complaint."

Cameron Coal Co., Carbon Fuel Co., Independent Coal & Coke Co., Spring Canyon Coal Co., Peerless Coal Co. and Standard Coal Co., all of Utah, have appealed to the Interstate Commerce Commission for a rehearing in the Western Coal Rates case, in so far as they affect rates from Utah and southern Wyoming mines. The operators desire to present further evidence with respect to the disposition and distribution of coal from Utah and southern Wyoming mines and with respect to the relative operating conditions encountered by railroads in the movement of coal from their mines. They point out that these companies have an aggregate investment in coal properties of \$12,200,000. These investments, it is contended, were made dependent, to a considerable extent, upon the 25c. differential fixed by the commission, with the expectation that the differential would be reduced, if not removed entirely. A differential of 50c. against Utah coal in favor of Rock Spring coal on traffic destined to points beyond Pocatello will have the effect of decreasing the movement of Utah coal to that destination territory, it is argued, thereby greatly depreciating the investments of the Utah operators. The slack content of Utah coal is from 33 to 35 per cent, it is pointed out. Utah slack in considerable quantities has moved to points north and west of McCammon, Idaho, under a differential of 25c. A 50c. differential will make it utterly impossible to ship Utah slack to that territory. Since decreased production results in increased operating costs, the establishment of the 50c. differential, it is contended, will inevitably result in increased prices of coal to the Western consuming public. The increasing of the differentials against Utah mines is held to be unwarranted and unjustifiable.

Coming Meetings

Illinois Mining Institute. Annual meeting Nov. 24, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

Second National Exposition of Power & Mechanical Engineering. Grand Central Palace, New York City, Dec. 3-8. Managers, C. F. Roth and F. W. Payne, Grand Central Palace, New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

West Virginia Coal Mining Institute. Annual meeting Dec. 4 and 5, 1923, Huntington, West Va. Secretary, R. E. Sherwood, Charleston, West Va.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 24

NEW YORK, NOVEMBER 29, 1923

Number 22

The Virginian Case

THE Interstate Commerce Commission is expected to reverse itself in the matter of the application of the Virginian Railway for authority to extend trackage to one of the new mines of the Pocahontas Fuel Co. Even those who want to see overdevelopment halted by denying trackage extensions will admit that the Commission could not have selected a more unfortunate instance in which to test the theory. In normal years the Virginian is able to supply practically all of the cars that can be utilized. The period in 1922 cited by the Commission during which the mines on that line had an inadequate car supply was abnormal because of the coal strike and shopmen's strike then in progress. The railroad company has been making an effort to meet the requirements of the mines on its line. More than \$13,000,000 will be expended on the electrification of 134 miles of its line, while more than \$3,000,000 is being expended in increasing its coal-handling facilities. These expenditures would not be justified were there to be uncertainty as to the rate at which coal-mining expansion would be allowed.

The whole question of throttling coal-mine development by denial of transportation is before the government now. The U. S. Coal Commission declared in one report that the distribution of coal "must be free and untrammelled," that there should be no discrimination, such as by assigned cars. The Transportation Act clearly places on the Interstate Commerce Commission the responsibility of holding railroad expansion within certain limits. What is in controversy here is not the authority but its application. That, it appears, is in a fair way of correction in this instance. The unsettling aspect, however, is the readiness, the unseemly haste, with which the Commerce Commission resorted to the exercise of this power in controlling the coal mines. Fired with the zeal of a crusader, eager to grapple with this giant of overdevelopment, the Commission assumed a position that it will be forced to abandon.

The Real Cloud

THE officers of the United Mine Workers would doubtless be happy indeed if they could today sign up a two-year renewal of the soft-coal contract that expires next April 1. Likewise the union operators, no matter how hard pressed they are now for orders to keep their mines running, would prefer such an arrangement, since the alternative is a strike. Now when both parties are of mind what is to prevent the happy consummation?

In the first place, John L. Lewis and his lieutenants must sell to the bituminous-coal workers the idea that two more years at the present scale is the best thing for them. He must sell it to men who have seen how easily the anthracite workers got their 10-per cent

increase in wages by playing into Pinchot's political campaign.

The soft-coal operators, being unorganized, are drifting into two camps: Those whose mines are idle or soon will be and who therefore would expect to profit by a prolonged strike, and those who, convinced that a wage reduction is out of the question next year, desire nothing more than to have uninterrupted operation. The large companies are all in this class. They can hold the others in line, barring outside interference.

The real cloud on the horizon is not a disagreement between union mine labor and operators; it is the warfare between the non-union operators and the union. To keep the union out of West Virginia the operators there have been aggressive in campaigns against the organization. They have led the fight against the check-off. Now the Lewis men fear that the hoped-for peace and tranquillity of their coming joint sessions will be disrupted by demands for abolition of the check-off. They are blaming the generation of this feeling on the non-union influence in the National Coal Association. Union operators also are saying that the persistent propaganda of the past year on "violence" has been driving a wedge between them and the organized workers.

One wonders then at the outburst of Frank Keeney, union organizer and local president, this week. Speaking as the captain of a loyal but decreasing band of union mine workers in West Virginia, he sounds his battle cry: The United Mine Workers has money and will assault the West Virginia stronghold this coming year. West Virginia operators always rally to such a challenge and the trouble starts anew. Mr. Lewis is the big boss; does he desire peace? Is this the way to promote harmony?

Selling Ford Coal

HENRY FORD is now a regular coal operator. He has a string of mines and is grappling with the production and marketing problems that beset the ordinary mortal who engages in this fascinating business. He has found that his mine capacity is greater than his immediate plant requirements and he is seeking to get rid of his surplus, for he, as have others, learns that part-time mine operation adds to cost.

Mr. Ford would eliminate fluctuations in coal prices and irregularities in production—for his friends and his mines. There are said to be around 300 concerns manufacturing parts for his car and he is taking a paternal interest in their coal supply. Not so long ago he sent to each of these 300 a questionnaire concerning their coal supply and their fuel requirements. If he can contract to furnish them all with coal as he in turn buys their products, he can make his coal-mining ventures successful and at the same time help these sundry manufacturers to have a steady fuel sup-

ply. As a coal operator Mr. Ford is animated by the same motives that govern every well-managed coal operation.

The difficulty he finds is that common to the trade—the coal consumers are not all far seeing, for some have indicated to him that his all-the-year-around price is much above what coal is now selling for on the spot market and that they are buying at the lowest price. He has the advantage, however, that falls to any consumer-operator of dictating, to some extent at least, to those who burn coal and sell to him. For instance, this fall one large concern that sells to the Ford plant a large part of its requirements in a certain line found, one morning, several hundred cars of coal at the gate. Mr. Ford had shipped them, invoice to follow. What had been a competitive market for the commercial operator became a forced outlet for surplus Ford coal.

As a coal producer, Henry Ford has yet to make his mark, but as a coal seller he has mastered the fundamentals.

Let the Railroads Pay the Bill

ONE of the principal duties of a chief executive in this nation of ours is to satisfy the voters—the most numerous class of voters, of course. In politics we are no longer concerned with minorities. In this country we should do as was customary at the hustings in England years ago. Dickens records Mr. Pickwick as going to a political gathering and advising his little band of followers, "Shout with the mob." Mr. Snodgrass replied, "But where there are two mobs?" Whereupon Mr. Pickwick said, "Shout with the largest." Our chief executive follows the advice of Mr. Pickwick. He also shouts with the crowd, for the voice of the President always is heard whether raised or lowered.

On Oct. 16 the President urged the chief executive of the Pennsylvania Railroad, Mr. Rea, and through him sought to influence the presidents of the coal-carrying railroads, to lower the freight rates on anthracite, not so much because domestic-coal rates are too high but because they are higher than export rates to Canada. It is hardly necessary to say that if domestic freights are too high they should be lowered and that it is an excusable point of view to hold that our own citizens should not have to pay a higher freight rate than Canadians. All this is obvious.

But at the same conference, and as it were in the same breath, the President asked the railroads to let American wheat be delivered to foreigners at a lower rate than to citizens of the United States. How is it that it is all wrong to let foreigners have a lower freight rate when coal is concerned and all right when wheat is to be shipped?

Let us suppose the railroads concede a lower rate on wheat to foreigners. What is to protect the roads when the consumer discovers that he is paying a higher rate? Will he not argue with wheat as the President is now arguing with coal, that the domestic freight rate should be the same as the export, and leave the railroads with a lower rate on wheat all around?

The railroad executives have made dignified and sufficient answer. They have advised the President that they cannot offhand concede the lower rates on grain, and that furthermore they doubt the efficacy of such a remedy, inasmuch as foreign farmers would meet their cut. The matter is to be investigated by the Interstate Commerce Commission. As to anthracite the answer

is obvious; the Coal Commission asked, and the Commerce Commission has initiated an investigation covering these rates. It is now in progress. We do not know what will happen to the grain rates but we are willing to venture the surmise that as to hard coal the final decision will parallel that of 1915. Some, possibly many, individual rates will be adjusted, but the rate level will be undisturbed.

The railroads are not yet in position to reduce freight rates generally, though they are making progress in that direction. That the Interstate Commerce Commission has just refused to open its grain case to all basic commodities is evidence of the situation.

But the President is right; it is good diplomacy to side with the larger number of voters—with the consumer as to coal, with the farmer as to wheat.

The Four-a-week Mind May Change

THERE is constant proof that coal miners' wages need no increase provided there are few enough mines and miners to justify regular operation. Only last month two loaders in an Indiana mine drew \$500 apiece. And in one particularly propitious day this pair loaded out 38 tons per man. In another mine in that state it is not uncommon for loaders to make more than \$400 a month.

This sort of thing occurs in these days of flat markets only in mines fortunately situated as to disposition of output. In most union regions such performance of miners is known to be invariably broken by layoffs and petty strikes, as at the Brewerton Coal Co. mine at Lincoln, Ill. There, because of an excellent railroad contract for engine fuel, the mine operated continuously all summer while many neighboring operations were lucky to get two days a week. Four months of this produced the inevitable result—the men, yearning for a vacation, struck because the check weighman objected one morning to a new housing around the beam of an automatic recording scale. It is an old, old story to union field operators. When a mine exceeds four days a week regularly—look out.

Harassing to mine owners though this four-days-a-week psychology of miners may be at times, it at least has the virtue of hastening the day of complete machine mining and loading. When that day arrives the \$500 a month that is excessive pay to an underground laborer now will be a good payroll investment if it goes to a machine operator who gets maximum service out of his machine. Loader operation should naturally gravitate into the hands of men of an intelligence superior to the four-a-week mental process. It is thus easy to be optimistic for the future even in the face of present discouragement.

THAT BRIGHT SCHEME for pumping screenings direct from the tipples 15 miles into St. Louis would be fine for Standard district producers except for one trifling obstacle: They have freight ills and coal mines and power and pipe lines, but yes, they have no water.

ORIGINAL CENSUS RETURNS analyzed by the Coal Commission showed coal-mine operatives in every state Jan. 1, 1920. Florida had 24, but no coal mines, so they must have been at Palm Beach. But how did New York register 299 coal miners, unless they were Greenwich Village miners?

Tipple of Mines Nos. 1 and 2, Phelps Dodge Corporation at Dawson, N. M.

Run Mines on Batteries? Every Wire May Be Removed At Dawson to Prevent Explosions

Phelps Dodge Corporation Tries Out Big 80-Cell Units for Haulage and Cutting—Adobe Dust, Water and Education Do Their Parts in Redoubled Safety Campaign at Stag Canyon Operations

WHEN a single electric arc in a coal mine kills 122 miners in one fatal burst of unbridled energy it is time to eliminate arcs, even at the cost of heroic methods. The Phelps Dodge Corporation, which operates six mines at Dawson, in the Stag Canyon region of New Mexico, is hunting for such methods. For one thing it has practically decided to remove every wire from every mine. This means operating the mines on storage batteries from slope mouths to room faces, with consequent engineering problems galore. But possibly it can be done. The company proposes to find out.

Also, it is applying every other method it can devise or discover to increase the factor of safety in its mines, even though they already have been provided for years with safeguards of the most rigorous kind. The precautions it had taken did not serve to prevent the explosion of Feb. 8, 1923, which killed the 122 men. A runaway load on the main slope knocked down haulageway timbers. This dropped a feeder power line onto the steel car, forming an arc which ignited coal dust. The aftershock of the explosion was felt almost as keenly by the company as by the bereft relatives. So "Safety—whatever the cost" is now the company's motto.

Eliminating wires from the Stag Canyon mines means putting all haulage and cutting on storage batteries. If mechanical loaders are installed, they too, of course, must operate on batteries. Storage-battery locomotives already have been used for some of the

gathering in the mines of the Stag Canyon group. The first move now is to install battery locomotives on main haulageways. This experiment is to be made first in No. 6 mine, where there is a 6,000-ft. main haul. Later it is to be introduced into the other mines, until the system is perfected for the whole group.

The preliminary order is for two 15-ton locomotives to be run singly or in tandem. The standard battery unit will be of 80 cells mounted on a four-wheel truck. When operated in tandem, two of these will constitute a locomotive 16 ft. 6 in. long, 57 in. high and 68 in. wide, which are approximately the dimensions of the heavy locomotives now being used for main haulage. The charge in each unit will be freshened each time the locomotive reaches the outside, which on an average will be once every hour. Complete charging can be done at nights.

To operate cutting machines, standard battery units can be assembled close to each machine in whatever numbers are necessary, though it is possible that one will serve each cutter. Most cutters now require about 50 hp. for efficient operation. As the battery units are large and as it is proposed to discharge them at nine times and to charge them at six times their rating, it is hoped that the standard units will deliver enough power to run the underground machinery successfully and that the time consumed in charging and moving batteries will not seriously reduce their efficiency. The life of batteries under such strenuous usage remains to be proved—a reason for proceeding with caution.

GENERAL OFFICES, HOSPITAL AND DISPENSARY

W. D. Brennan, the general manager, has much confidence in storage batteries and has already done some pioneering with them for coal-mine use. He thinks it is possible for a mine to operate its underground works entirely on batteries and to charge at night when the load at a central station is light, buying electricity for night charging accordingly at a most favorable rate and being enabled to reduce by 75 per cent the capacity of its own power plant. In consequence the generally prophesied increase in power costs by the use of batteries may be largely counterbalanced at the Dawson mines by economies, not only in the plant but in transmission, mine accidents being reduced at the same time.

Other steps have already been taken in the Phelps Dodge mines to raise the safety factor. Adobe-dust barriers of the trough type have been installed at intervals in main and side entries. Also the practice of spreading adobe on floors along particularly dusty 1,000-ft. stretches of haulageway has been adopted. Non-inflammable dirt of this character can be obtained at the surface for the cost and trouble of loading it into cars, running it into the mine and distributing it.

The roadway to be treated is first cleaned of loose coal. Then about 3 in. of adobe ranging from coarse to 100-mesh is shoveled over the exposed surface. Once a month men with rakes go over it, working the inflammable coal dust safely down into it. Eventually the percentage of coal in the floor dust becomes so high that it is thought well to clean the roadway of the mingled coal and adobe, and another layer of the non-inflammable dust is spread. This is considered good protection against dust explosions in mines such as these, where dust is a real and constant menace.

Water always has been liberally used in the Dawson mines. It is piped to every room and used to wash

PHELPS DODGE CORPORATION'S STORE AND HOTEL

down entries. But since the explosion additional use is made of water. All outgoing coal is wetted thoroughly with it. Sprinklers have been installed at both the first and last partings so that whereas coal used to be moistened only on its way out it now is drenched, not once but twice.

For years the company has worked hard at promoting safety, believing that the safety spirit, if it is to be effective, must be actively shown by everyone from the highest official all the way down to the least important employee. W. F. Murray, safety engineer for the company, told the Rocky Mountain Coal Mining Institute something about the safety work at the Dawson mines in an address at a recent meeting. A part of his paper follows:

"Under the system in operation at the Dawson mines a safety engineer is provided to insist on compliance with the rules established to promote safety and to see that all safety equipment is kept in efficient working order. At least once a month the safety engineer, in company with a safety committee consisting of a miner, a company man and the mine foreman, makes an inspection of the working parts of all the mines to ascertain whether conditions are such as to assure safety

HOSPITAL OF PHELPS DODGE CORPORATION

He makes a formal report as to his findings to the manager.

"As is usually the case, men on these safety committees after having gone through the mines to examine other men's places are careful to keep their own working places in such good condition that the men following them will not find that they themselves have neglected to make their places safe.

"It is indispensable that the mine foreman believe in the value of these committees and that he realize that the committee is not there to criticize his work but rather for the purpose of assisting him in presenting to the uninstructed or careless workman by practical suggestions the manner in which the greatest degree of safety can be attained.

"As is the case in this day and age, the majority of workmen in the mines are composed of those whose education has been neglected and whose experience in the mines is limited, and in a great many cases accidents which have occurred to these men may be traced to the fact that they were not fully instructed as to the proper method of performing certain of their duties or that the instructions were not understood. It is to this class of workmen that the safety committees pay special attention. The proper methods of erecting timbers, placing cap pieces, drilling shotholes, spragging coal, blocking cars, etc., are explained. As the majority of people are susceptible to criticism, much efficient

work can be accomplished if care is taken to show the workman that his work is not being criticized for any other purpose than to reduce his liability to injury.

"At the Dawson mines, for the information and guidance of the new employee, the company gives him a set of published rules, printed in the various languages used by the several nationalities employed at the mines. These describe the safety rules in effect at that operation. They not only cover the duties which the miner must observe under given conditions but they describe also the special duties of the mine foreman, fireboss, shotfirer, timberman, trackman, drivers, motorman, nippers, fan attendants, and tippelmen. Each man entering employment for the first time also is given a copy of the state mining laws.

"Free picture shows, at which are displayed the safety films furnished by the Bureau of Mines, are employed to portray through the effective medium of the eye those safety truths that might otherwise never reach the heedless or illiterate miner. Throughout the mines safety signs and slogans are posted in conspicuous places to recall to the miner his constant exposure to danger and to keep him alert to its presence.

"Somewhat of an innovation has been made in teaching the lessons of safety by introducing them into an annual Community Night program. Community night is an evening set apart for the social enjoyment of the miner and his family. The program for last year was presented in the form of a vaudeville show, the five members of the safety department who took part in an act being starred as the 'Black Diamond Quintet.'

"In this act, a rescue team with complete equipment entered the darkened stage and demonstrated the rescue of a miner overcome with gas. Immediately following this demonstration a short talk was made relative to the use of the apparatus, its method of operation, and other points of interest. In this manner the interest of the miners' wives and families in the safety movement was aroused.

"Posted in a conspicuous place under glass cover at each check cabin of the mines is a large blueprint showing a graphic representation of nine 'thermometers,' representing the nine Dawson mines, upon which are designated by means of a graduated scale the number of serious accidents occurring at each mine during each month of the year. Beginning with the month of January, the red line which simulates mercury climbs one degree for each serious accident. At the end of the year the total record for each mine for the twelve months is graphically shown, month by month.

"For the purpose of registration and comparison, a serious accident is considered to be one which prevents resumption of work in less than 14 days. Fatal

FEDERAL VOCATIONAL COURSES—MECHANICAL DRAWING

accidents are included in this class. The period of disablement starts the moment the accident occurs and ceases the moment the workman is released by the doctor for return to work.

"The story told by the thermometers is visual and readily understood, provoking at least some reflection on the part of the miner who studies it. Twice daily as the miner calls for and returns his check, that constant reminder stares him in the face and draws to his attention the fact that the price of his safety is constant vigilance.

"Undoubtedly, the greatest value of this device as an incentive to safety is the opportunity it affords the miner and mine foreman for making a ready comparison between the number of accidents happening in his own mine and those occurring in the other eight. It stimulates in them both, an instant and natural desire that the mine in which they work shall have the reputation of recording the smallest number of accidents.

"Believing education to be an important asset to the welfare of a mining community, classes in mining science have been conducted under the supervision of the Federal Board for Vocational Education. These were started in September, 1919. Classes were also organized in mechanical, architectural and electrical drawing.

"In conformity with the vocational-board ruling, classes in mining are limited to underground men. These restrictions do not apply to the drawing classes. Anyone working in and around the mines is eligible to receive instruction in this training.

"As the instruction is free, men from all classes and drawn from all countries are enrolled. During the past year the nationalities represented were: American, Scotch, Welsh, Mexican, Italian, and Slavish and consisted of miners, drivers, motormen, nippers, track-

CLASS IN COAL MINING IN PUBLIC SCHOOL

WHERE MEN ARE TRAINED IN RESCUE WORK

layers, shotfirers and firebosses. Classes are held in the afternoon for the men working at night and in the evening for the men on the day shift. The ages of those enrolled range from twenty to forty-two years.

"The subjects taught consist of the following: Mining arithmetic, mine gases, mine ventilation, safety lamps, timbering, and shotfiring. Safety ideas are incorporated in the teaching of the various subjects, and the state mining laws are discussed.

"These classes are held for a term of nine months, at the end of which examinations to determine the students' proficiency are held, and the successful candidates are given a certificate issued by the state board for vocational education. During the past term fifty-three men were enrolled in these classes.

"The work of instruction is encouraged by the management in every way, the training station and its conveniences being freely offered for its use, books and periodicals being supplied and opportunities offered for practical demonstration.

"Realizing that the workman born in a foreign country, in order to become more efficient in his work and follow the ordinary rules of safety, as well as become a good American citizen, must know and understand the English language, the Phelps Dodge Corporation has for the past three years conducted night schools in all four of the Dawson school buildings. From a safety point of view the work is helpful, because the men learn to read well enough to understand the different safety and danger signs. They acquire enough English in a short time to enable them to understand and appreciate lectures on first-aid and safety precautions.

"A well-equipped training station, unique in some of its features, has been built and maintained solely for the use of the safety department. This two-story cement-block building was completed in 1910 and accommodates on its second floor a commodious first-aid and class room, the safety engineer's office and a reading room. The lower floor contains a storeroom, apparatus room, furnace and training gallery. Leading from the back of the training station into the side of the mountain, against which the training station is built, a training gallery has been driven. This gallery duplicates in construction a double entry underground and contains the features found in an ordinary mine.

"Classes in the use and care of oxygen breathing apparatus are conducted twice a week. One class meets during the day for the benefit of those working at night and another class meets in the evening for those who work during the day.

"The candidate for mine-rescue work must undergo

SMOKE CHAMBER, TRAINING STATION

a thorough physical examination. Before he is permitted to wear a machine he must familiarize himself with the apparatus, be able to designate the different parts, assemble them and test the machine. He is then required to wear the apparatus in normal air for a time, after which he is ready to enter the training

gallery, with its formaldehyde fumes. Here he is compelled to crawl over and under imposed obstructions, arranged as in a wrecked mine, and to work with various tools, setting timbers, etc. In this training, emphasis is placed on work such as would have to be done during a mine fire or explosion.

"After completing fifty hours' training with the use of the apparatus and having completed a satisfactory examination, the student is then considered thoroughly adjusted to the use of the apparatus and is given a certificate from the company, indicating that he is a trained man qualified to use and care for mine-rescue equipment."

Washery Water Improves Farm Lands

THREATENED with a suit by farmers and others for having destroyed the quality of the land, the Galloway Coal Co., of Holly Grove, Ala., induced the Department of Agronomy of the Alabama Agricultural Experiment Station at Auburn, Ala., to test the effect of the mine and washer water on the soil thus alleged to have been destroyed.

This was done by growing corn and velvet beans in it and supplying them with distilled water, water from the Auburn mains, water from the "contaminated" Lost Creek and from the Galloway washer. Five samples each of 300 lb. of soil from five different farms were used and several gallons of the different kinds of water. A fifth test was made by adding acid phosphate as a fertilizer to the various waters. Better growth was obtained with the creek and coal-washer water than with the distilled and Auburn water, and still better success with water containing acid phosphate.

The department offers to make a test next spring on a farm along Lost Creek to show that if the soil is fed with fertilizer supplied by the department much can be done with it and that the coal-washer water will aid in the stimulation of the ground. The conclusions of the Auburn Experimental Station were: That water from Lost Creek or from the coal washer at Mine No. 15 of the Galloway Coal Co. is not toxic to corn in sand or water cultures, nor to velvet beans in water cultures; that neither contains anything that would injure the growth of corn on lands flooded by Lost Creek and that these waters contain a small quantity of plant food in solution but not enough to be of benefit to the growth of corn in land thus flooded.

RESCUE MEN READY FOR UNDERGROUND TRAINING

Illumination by Light Projectors at Coal Mines

Need for Greater Application of Advanced Principles
in Correct Illumination—Hazards of Poor Lighting—
Function of the Reflector—Focusing the Headlight

BY EDGAR GEALY

Electrical Engineer; Associate Editor, *Coal Age*

BECAUSE of the very nature, location and processes through which its product must pass before being placed on the market a coal mine always suggests a black, dark place. Therefore it is natural to conclude that the coal mine is a field where the theory and ideas of illumination and light projection have been carefully applied. However, this is not the case; in fact, generally speaking, the coal field is a region not so well illuminated as one would expect.

Much has been done of late in the way of proper illumination in stores, factories and homes. It has been conclusively proved that improper illumination produces eyestrain, fatigue, cuts down production and increases accidents.

Then again, large savings in lamp costs, labor charges and power consumption are possible by the use of proper reflectors. In many mines and around mine properties it is an uncommon sight to see large candle-power lamps hanging without reflectors. In hoist rooms much can be done to decrease the liability of accident by the use of angle-type reflectors.

Perhaps the most necessary place for proper illumination is at the foot of the shaft or at a caging level. Here it is highly desirable to have efficient lighting units because it is the heart of the transportation system and delay here due to loss of light, insufficient light, or accident cuts down the output. For these reasons lights should be carefully located and provided with reflectors to direct the light not onto the top of the car, where it is useless, but between the double tracks, where used, and on the sides where the wheels can be seen so that the cars may be properly handled and controlled.

In the main haulage roads, gangways and entries lights should have reflectors so as to properly illuminate the roads and track and not the roof, where most of the light usually is wasted.

Light projection by means of reflectors also finds its place on the outside property of the mines for protection purposes and inside the mines on the locomotives of the haulage system. It is this phase of illumination which most interests us at this time.

Much of the efficiency of a light source is frequently lost because of a lack of understanding of the proper focusing of lights. This is not only true of mine locomotive headlights but also of automobile headlights and light projectors used for property protection and other special purposes. The result is that lamps of much larger size than is necessary are used for certain desired effects.

Light projection, as the term is commonly employed, covers the redirection of light flux emanating from an artificial source by means of suitable optical systems so that it may be utilized within solid angles which are small as compared with those encountered in equipment for general illumination purposes.

Two general classes of apparatus are used to direct the flux from a source into the desired small angle: Opaque reflector systems controlling the light by the principle of specular reflection, and lens systems depending upon the refractive properties of glass. It is the first of these classes which is involved in headlight reflection.

All light sources may logically be broadly classed under three heads: Point sources, line sources, and large sources, i.e., sources having length and breadth, or length, breadth and thickness.

Polished metal and mirrored surfaces reflect light rays in such a way that the angle of incidence is equal to the angle of reflection. The shape of a parabolic reflecting surface is such that all light rays which are parallel to the principal axis and which strike the surface are reflected to a common point on the principal axis, called a focus. If a point light source is located

FIG. 1—LIGHT SOURCE AT FOCAL CENTER

The light rays are parallel to the principal axis and produce a long, narrow beam.

FIG. 2—LIGHT SOURCE AHEAD OF FOCAL CENTER

The light rays converge to the principal axis, then diverge and produce a broad cone of light.

FIG. 3—LIGHT SOURCE BEHIND FOCAL CENTER

The rays diverge and produce a broad cone with a dark spot around the principal axis.

FIG. 4—LIGHT SOURCE AT FOCAL CENTER

The reflector is completely illuminated, the beam is intense and narrow, the light spot is uniform.

at the focus of a parabolic reflector, the converse holds true—that is, all the rays from the focus which strike the surface are reflected forward, parallel to the principal axis in a uniform beam.

The effects produced by a point light source in these positions along the principal axis of a parabolic reflector are shown in Figs. 1, 2 and 3. It will be seen in Fig. 1 that the source at the focal center results in a parallel beam, and the source in front of the focal point, Fig. 2, causes the light rays to converge, cross and later diverge; Fig. 3 shows that the source between the surface and the focal center results in a divergent beam. A line source lying in the principal axis and extending behind and in front of the focal point would produce these three conditions together, with the result that a very irregular light distribution would result.

It should be borne in mind, of course, that no matter where the source is located, the light emitted within the solid angle determined by the rim of the reflector and the source does not strike the reflecting surface at all and is therefore distributed as a broad cone, useful for illuminating nearby objects outside the path of the beam, but contributing only very slightly to the intensity of the beam itself. Referring to Figs. 5 and 6 it will be seen that of two reflectors of the same diameter, the one with the shorter focal length will reflect the greater volume of light.

From the foregoing it is apparent that a light source for projection work in general should be of small dimension. Other features to be considered are high intensity, convenience, interchangeability, dependability, steadiness of the light, economy, and safety.

Two sources of light for projection purposes are in extended use: arc lamps and mazda concentrated-filament lamps. Arc lamps emit their light from a very small source of extremely high intensity. Direct-cur-

rent arcs are more efficient than alternating-current arcs because most of their light is emitted from the permanent crater which is formed in the end of the positive carbon, and a considerable part of the light from the crater may be directly utilized. Arc lights usually are supplied with a resistance or reactance to give stability of operation. Mazda-lamps admirably meet the requirements of projection sources and because

FIGS. 5 AND 6—PROPORTION OF REFLECTED LIGHT

These two reflectors are of the same diameter yet the one on the left reflects a greater proportion of the light because it has a shorter focal center.

of their simplicity, convenience, and the fact that they may be obtained with filaments either condensed or well spread out, they are particularly adapted for projectors such as locomotive headlights, spotlights, etc.

In mining service nearly all types of equipment must withstand severe conditions and this is especially true with headlight equipment. Mining service is divided into two main classes, gathering service and main haulage. As gathering service usually is slow and fre-

FIG. 7—LIGHT SOURCE AHEAD OF FOCAL CENTER

The reflector is dark at the rim, the beam is broad and the light spot is dark at the center.

quently on very irregular and curved track, too strong a light is objectionable on account of its dazzling the eye. A long projected light beam is seldom required either, yet there should be sufficient light cast over a broad area for coupling and switching. Main haulage service is at greater speed and usually on straight road, therefore the light beam should be long and more intense so as to sufficiently illuminate the haulageway well in advance of the locomotive.

Where the trolley voltage varies over wide ranges the arc headlight will be found to operate much better than incandescent lamps, which as a class are very susceptible to fluctuations of voltage. Under-voltage materially reduces the illumination while over-voltage generally reduces the life of incandescent lamps.

The selection of a headlight lamp for mining incandescent headlights is therefore one requiring much consideration if the best results in illumination, efficiency, and economy are to be realized. From the very nature

of the work of the gathering locomotive regular filament lamps may be used with success because the light source is not concentrated and the result is that a broader cone of light is obtained. On main haulage motors it is desirable to use a concentrated filament or focus type lamp.

An important consideration in connection with the selection of any incandescent lamp is that the lower voltage lamps give best results. High-voltage lamps are not nearly as reliable nor as efficient as 110 to 125-volt lamps, because the filaments of the higher voltage lamps are made of a longer, finer wire than the lower voltage lamps and therefore cannot be wound in as small a space. Lamps of low voltage are wound with a short, heavy wire, which can be concentrated in a smaller space and which will withstand vibration better than the higher voltage lamps. As a matter of economy it is desirable to adopt a lamp of low yet popular voltage. For this reason some com-

FIG. 11

Main-Haulage Road Illumination

Obstructions and switch locations must be spotted well in advance of a fast moving main-haulage locomotive. For these reasons the headlight beam should be narrow and more intense than on the gathering locomotive.

FIG. 9—CURVE SHOWING LOSS OF CANDLE-POWER WITH DECREASE OF APPLIED VOLTAGE

A 10-per cent drop in voltage results in 15-per cent drop in candlepower. A 20-per cent drop in voltage cuts the candlepower to less than half normal. To get a certain quantity of light where overrated lamps are supplied the user, he is forced to adopt larger lamps. This is very uneconomic owing to the extra cost of the lamp which is larger than would be necessary if it were of the proper voltage.

panies have adopted the mill type 115-volt lamp which is also used in buildings having considerable vibration and also for extension lights. This selection minimizes the numbers of different types required for stock.

The most important consideration in the effectiveness of a headlight or other type of projector beam is to have the light source located at the focal point of the reflector. Incandescent lamps are likely to vary in the length of their light centers, and for perfect adjustment it is necessary that the receptacle be adjustable so that the filament may be located at the focal point of the parabolic reflector.

To properly focus a headlight it should be located in a place as free as possible from other illumination and

then adjusted until the best light beam is obtained. Another method is to throw the beam of light on a wall and move the lamp within the reflector until the smallest illuminated spot is obtained. A little practice will enable one to focus the lamp quickly and accurately.

Fig. 4 shows the conditions which result when the lamp is in proper focus—1 shows the reflector evenly illuminated; 2 shows the resulting narrow light beam, and 3, the spot of light produced on a screen. Fig. 7 shows the conditions resulting when the light source is ahead of the focal center. Here 4 shows the rim of the reflector illuminated, resulting in the divergent then convergent beam, 5; and the result obtained on the screen is shown at 6.

When the light source is behind the focal center the results are as shown in Fig. 8. The reflector appears as shown in 7, the beam is divergent as shown in 8, and the spot on the screen has a dark region as shown in 9.

From these photographs it becomes obvious just what adjustment should be made to a headlight to put the light center in proper focus. The adjustment may therefore be made by observing the reflector, the light beam or the spot of light resulting on a screen or wall.

BIG BUILDINGS LOWERED BY SUBSIDENCE.—Interesting developments in the problem of surface subsidence resulting from mining operations were observed in Great Britain and France, according to George S. Rice, of the U. S. Bureau of Mines. At St. Etienne, France, mines have passed under important buildings which have been lowered as much as 20 ft. without material damage, because of the careful packing methods employed. The mine subsidence problem is one of growing seriousness in various European countries. The English Parliament has recently established a commission to study the situation, with a view to recommending special remedial legislation.

FIG. 10

Headlight on a Gathering Locomotive

Short turns, switching, coupling and door opening require a headlight with a broad beam for general illumination.

Wherever Roads Meet, Time Is Likely to Be Lost

When Loaders, Locomotives and Tipplesmen Stand Idle Can Haulage Control Afford Them Steady Work? *

Lack of System Results in Loaders Being Idle One-Fourth, Main-Line Locomotives One-Third and Gathering Units One-Tenth of Duration of Shift—Haulage Control Would Save Time

THE effect of an irregularity in the supply of empties upon the work of the individual loader is shown in Fig. 1 for eight separate days in six different mines. The chart shows not only the time the loader lost waiting for cars but the irregularity in the time in which they were delivered to him. In general it will be noted that this irregularity becomes more pronounced during the latter part of the day. The time lost by each of these loaders, due solely to the fact that he did not receive cars, is shown in heavy black. The maximum time lost by any of the loaders noted was two hours and forty-five minutes in an eight-hour day and the minimum time seventeen minutes. The average time lost was one hour and fifty minutes, representing 23 per cent of an eight-hour day.

The upper jagged line for each mine shows by its three horizontal levels whether a car was being loaded (highest level); was loaded and waiting to be drawn out (level 70 per cent above base); or whether there was no pit car at the loader's place of work (40 per cent above the base line.) If the loader left his working place before the completion of eight hours (in addition to his lunch period) the rest of the eight hours is drawn with the upper line sloping downward, the reason for his quitting being indicated by the kind of

shading. Detail information regarding physical conditions and equipment in these mines may be found in subsequent tables in this report by reference to mine designations.

Referring to the mine *DS* at the top of the diagram we see from the downward verticals that the man loaded five cars. During the first four hours, though there were periods after each load was completed when he had no cars at the face, as shown by the lowest horizontal lines, he was busy on other work. After loading his fourth car he had to wait about twenty minutes for the next car and on loading the fifth car he waited about one-half hour, then learned from the driver that he would not be given another car on that day, and so quit work.

The driver gave as his reason for not giving this loader another car that he had had his turn and that he must give what other cars came in that afternoon to other loaders. At this particular mine the management claimed they had a sufficiency of mine cars to furnish the men at their places all the cars they needed for loading coal. The chart shows, therefore, that either this was an exceptional condition, that the management was misinformed as to the condition, or else did not use the right method in determining the number of cars necessary to provide the men all they needed.

It is believed that the conditions shown in the chart are not exceptional, especially as the natural tendency on the part of officials during a special test is to pro-

*Fourth Installment of Report on "Underground Management in Bituminous Mines" made by Stanford E. Thompson and associates to the U. S. Coal Commission. The three earlier installments appeared Nov. 8, page 691; Nov. 15, page 733 and Nov. 22, page 773. Other installments will follow later.

vide at least as good as average conditions. Furthermore, other working places in the same mine were visited and other loaders found waiting for cars.

It will be further noted that the time in which the miner loaded each car was fairly uniform, but that the time between delivery of the cars to him increased steadily from the first to the last. There was no particular plan or schedule of delivery of these cars, and the miner never knew in advance whether he would get an empty car in ten minutes or in two hours after his loaded car had been pulled.

The next three sections of the diagram show three consecutive days of the same miner in the same mine designated as *RM*. This record was taken to show a complete cycle of work from clean-up to clean-up. Note that for the first forty-seven minutes of his first day's work he had no car at his place, but at this stage of the cycle he had plenty to do and the failure to deliver him a car did not cause him to lose any time. During the balance of the first five hours of the day he was kept well supplied with cars, followed by a lapse of two hours and eight minutes during which he received no cars.

That only forty-seven minutes of this time was actually lost waiting for cars is due largely to the fact that it was still fairly early in the man's cycle and much other work remained to be done besides the loading of coal. Toward the end of the second day his periods of waiting for cars became more numerous, as he had more nearly completed the work of his cycle other than loading, and on the morning of the third day the greater part of the time during which no car was in his place was lost time to him.

On this last day we see that the loader quit after five hours' work because his place was cleaned up and there was no cutting machine available. At this mine also will be noted great irregularity in the time of the delivery of the cars and also a big variation in the time the miner took to load them.

In mine *TS*, where two miners loaded at one working place, is seen a great irregularity in time of delivery and a total of two hours and four minutes loss per miner during the day waiting for cars.

Mine *SP* represents on the whole probably the best conditions of management seen at any of the mines. This is borne out by the chart which shows no time was lost waiting for cars until after six and one-half

hours of the working day had passed, the delay in this case being due to a break in the power line which affected the whole mine.

Mine *AS* also shows comparatively little time lost waiting for cars, the haulage at this mine also being much above the average of those observed. In this case, the miner, who was an exceptionally skillful man, quit after loading five cars and earning \$8.60 because he was satisfied with his day's work. The ordinary rate of loading of this particular man, as shown by the payroll, was six cars per day.

Mine *OW* shows fairly regular delivery of cars, which came in pairs, but they never were delivered with such frequency that the miner could fill up his time in other work, and the miner, therefore, lost an hour and two minutes in the day for lack of cars.

Variations in haulage details at individual partings studied in various mines are shown in Table I with average maximum and minimum figures. Note the great variations in the number of miners cared for by each mule or locomotive at any particular parting as well as in the number of cars gathered per day. These variations, barring certain conditions in length of haul and grade, are due almost entirely to the lack of supervision or order or any studied planning or dispatching of the haulage system. A few figures also are given in this table showing the actual labor cost per ton for gathering coal at these partings and total time lost at these partings due to various causes.

Table II shows the operating time lost by four locomotives in a large mine in a day observed. Note that total waiting time is 34 per cent of the day.

Averages in Table III, made up from the material detailed in preceding pages show the average losses of total available operating time, due to the failure of the haulage system to function properly, which always occur in such work, especially under scant supervision.

General Principles of Haulage Control.—To bring out the faults of any scheme is of little constructive value unless one can reach down and determine the basic principles at fault and indicate the general lines along which improvements may be accomplished. A side light is thrown on mining by comparison with manufacturing industries. Not long ago a past president of the American Society of Mechanical Engineers speaking on

the "Science of Engineering," and leading up to the recent developments in the science of operating management, stated that he could "remember distinctly the time when an educated scientific mechanical engineer was looked upon with profound suspicion by practically the whole manufacturing community."

The mining operator appreciates the engineer in so far as his work relates to design and layout. But our studies show that with a few exceptions, the mine below ground is in the same stage of development as was the manufacturing industry before it arose to an appreciation of the place of science in management.

The conditions in underground haulage which have been illustrated exist because fundamentally mine officials still fail to appreciate the need for keen analysis in each individual mine of all of the different variables and fail to see the need for the installation and the operating maintenance of routine plans which may involve the employment of a clerk and a little paper work, a thing abhorrent to the old-fashioned mining official.

Care must be used to see that any plan adopted is not merely left to run itself, as is so often the case in all industries where such work is the result of somebody's "hunch" instead of being based on definite principles. In one mine visited, for example, the management pointed with pride to a blackboard at the parting, on which were a number of figures.

Quoting from the report of our industrial mining engineer: "The general superintendent directed the trapper who kept it to explain it to us. The trapper replied that he kept a record of the number of cars that each gathering locomotive pulled by jotting down how many it brought out in each of its trips. The general superintendent then said 'Tell them how you kept your record of the number of the men each locomotive is pulling from.' The reply was, that was obtained by asking the driver, the figures being put at the top of the board, but that the driver hadn't reported yet that morning.

"We went on further into the mine, and as we went the superintendent explained that by getting such records every night a close supervision of the haulage system was kept at the office. Later when the superintendent had left me, I went back and questioned the trapper who kept that particular board. I noticed that still no figures appeared of the number of loaders that were being supplied with cars in the course of that day and I asked him if the driver had not reported yet. The reply was 'Oh, I don't keep that any more. They started this ——— system a few months ago and I kept it for a week, but one morning the driver didn't tell me the number of men in and I forgot to ask him, and I never kept it after that.'

"I watched him for a while, and within an hour he made three mistakes in putting down on the board the figures of cars hauled, one in the actual number of cars

brought in and two in making his additions. In the mine office the following day I examined the report made from the figures kept on the blackboards at the partings. For some of the locomotives, figures were given as to the number of loaders from whom they were hauling. In other cases the spaces were blank, but after each appeared the number of cars hauled the previous day.

"Disregarding any special cases of locomotives pulling from gangs on development work, the figures showed one locomotive pulling from anywhere between thirteen and thirty-five men and from forty-six to one hundred and twenty-six cars. Such a report had been going to the superintendent's desk daily for several months, and apparently the manager believed that thereby he was exercising close haulage supervision, yet underground, as a matter of fact, haulage locomotives were running without schedule, blocked by cars, and pulling greatly varying loads. Gathering locomotives and their drivers were waiting for empties and operating with widely different efficiencies. Miners, meantime, were waiting for cars!"

The plan failed because of the disregard of fundamental principles in management, for in the first place planning was not differentiated from operating, and in the second place the plan was simply an accumulation of the records of what had been done, instead of a conspectus of what it was advisable to do.

EACH MINE MUST HAVE PLAN TO SUIT ITS NEEDS

No method of procedure to be followed for the installation of a scientifically planned and dispatched haulage system applicable to all mines can be outlined in a report of this nature, nor can methods be laid down for a particular case that might not have to be modified as the work proceeded. Furthermore, in practice, as is discussed later in this division of the report, any plan should be tied in with, and form a part of, a comprehensive scheme which includes with the co-operation of the miners the analysis and planning of the work of all the men in the mine for the purpose of bringing more clearly before the operators and miners the general principles involved in planned and dispatched haulage from an engineering standpoint.

TABLE III—TIME LOST IN A DAY THROUGH LACK OF SYSTEM IN HAULAGE

	Hours	Minutes	Per Cent
By the miner at the face.....	1	50	23
By the gathering locomotives and drivers.....	0	44	9
By the main-line locomotives and drivers.....	2	43	34

That the problem is no simple one is indicated by the principal factors that must be considered: Capacity of the hoist or main haulage equipment; capacity at bottom; empty-car track capacity at same point; capacity of partings; location of working places with reference to each other and to the partings; location of partings; grades on haulage roads; number and location of miners in rooms and entries; number and size of locomotives and cars; weight and condition of tracks and length of hauls; distance of main partings from shaft or drift mouth; size of room; mining conditions as affecting rate of mining and such local rules and practices as affect the foregoing conditions.

It should be noted at the start that of these major factors affecting the haulage problem all are susceptible to modification by the operator, with the exception of the major grades on the haulage roads, mining condi-

FIG. 1—ANALYSIS OF SOME MINERS' WORKING DAYS
Only peaks show loading times, loaded and waiting is the level below the peak and no car in place the lowest level of all. The sloping lines show time in which miner has left his place satisfied with his day's work.

tions as affected by law or the physical and geological characteristics of the coal seam.

The problem in every mine resolves itself in its primary aims into the necessity of providing the required number of empty cars to each miner at the time he needs them and hauling the full cars to the parting, and thence to the bottom or to the tippie and returning the empties into the mine without permitting congestion at any point, the number of miners to be regulated by the production desired. In each case the problem can be solved by a thorough analysis that will determine the facts. In this analysis not the costs but the actual time should be ascertained. Thus equipped a good working plan can be devised.

In a few mines are to be found the rudiments of transportation control. Reference has been made to the mine *SP*, Fig. 1, where the supply of cars is exceptionally uniform. This is not mere chance, for this mine employs a traffic foreman underground. Many mines have their haulage practice so definite that the management knows early in the morning what working places are available and the expected tonnage for the shift. They also know the number of men in each section, and where excess, if any, can be used, so that they have at least a part of the information needed for the dispatching of cars.

In other mines which we found to be the best organized and lowest in operating costs for given physical conditions, these various elements had been studied and a traffic man designated to supervise in a general way the running of the trips. With an extension of these duties, in accordance with recognized practice in manufacturing, naturally comes the noting each day* of the location of active working places and of the men working; the allocating of drivers and locomotives with the formulation of definite schedules of trips and number of cars to the trip; co-ordination of the work by telephone communication to supplement these plans

*Perhaps by pins on a mine map as is done in one or two instances, or by further utilizing the check system.

just as in a factory. There the production man—that is, the planning official—keeps in touch with the production and changes details as needed, while maintaining always his general scheme.

While details may be left to local treatment, such general principles as these apply to all mines. They are in accord with the policies of control that are being followed by the best industrial organizations in all industries. The adoption of these will go far toward relieving one of the most potent sources of friction between the miner and the manager by furnishing an equitable delivery of mine cars to the loaders.

Tendency to Minimize Importance of Haulage Control.—That the mine manager gives too little attention to the problems of efficient underground haulage is due in part naturally to the fact that when a loader waits for cars, or consumes—by reason of the management's demand that the cars be excessively topped—additional time over that required for straight loading, he alone stands the primary loss because he is on a tonnage or piece-work basis, and when he is idle he presumably is not costing the company anything.

On the other hand, the larger the load per car, the lower the apparent haulage costs per ton. In this neglect of the management to insure the maximum production desired by the miner, the fact is overlooked that any lost time of the miner, such as that caused by lack of cars or excess topping, is eventually reflected in demands for increased rates of pay.

A rather common viewpoint of the operator is expressed in the following communication from an executive of a large Western mine. Although this is written in connection with a statement on machine loading, an interesting feature is the reference to the haulage problem:

"The outstanding difficulties suffered are those occasioned by the persistent resistance to the use of power shovels made by the mine workers, backed by the force of their organization. A continuous controversy rages regarding the distribution of empty cars as between the hand loaders and the shovels, the men demanding that cars be placed when and as they want them, the speed used in loading out cars in individual rooms varying 200 per cent or more, the hand loaders demanding that such preferential service be given them as will admit of their loading out what they consider their daily quota in less than eight hours (never more than 6½ hours), failure to meet this demand resulting in the shovel operators so handling their work as to cause delays of one or two hours per day to the shovel and its crew, including the room driver engaged in placing empty and loaded cars."

Without in any way condoning this antipathy to the power shovel it may well be questioned, judging from the way it has been found possible to handle similar irregular conditions in other industries, whether the operator on his part should not manage the haulage problem so that the miners will receive such cars as they require notwithstanding a variation in demand.

Savings in the productivity of labor not only reduce overhead but tend eventually to lower unit labor cost. In fields where both tonnage rates and the day pay of company men are fixed regardless of physical conditions, the results become effective more slowly than where there is greater freedom to reward a man for conscientious effort, but in both cases the eventual result will be the same.

Why the Coal Industry Of Great Britain Functions Smoothly

Car Shortage Unknown—Few Mines
Work One Shift—Priority in Use of
Cars Would Cause Riot—Storage and
Profit-Sharing Stabilizing Factors

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

THE reason why Sir Richard Redmayne was selected to serve as chairman of the coal-mining organization committee of the United Kingdom during the war is apparent before you talk with him long. Like most of the other busy men I met in Europe, he was willing to make any sacrifice of time if he could contribute to a constructive effort. Nowhere did I meet a coal man in the United Kingdom who was not willing to lay his cards on the table once you had established the fact that the material was to be used in an effort to benefit the coal industry.

I was apprehensive before I went that they might be inclined to have little to say on the ground that it would be giving a competitor the advantage of their experience. This was not the case, however, despite the fact that American competition is being felt much more keenly than our export tonnage warrants. It is quite evident that they fear our potentialities in that direction. During my stay in Cardiff, sales of American coal were made in France, in direct competition with Welsh interests, and while I was in Newcastle, American bidders were successful in Holland—a market that has been almost exclusively Newcastle's for a generation. They were somewhat chagrined at our success in those markets and they were at a loss to understand how we could quote the prices we did.

I encountered many readers of *Coal Age*. In several offices the well-thumbed copies indicated that they were read by the entire staff. Sir Richard keeps the more recent copies on his desk for ready reference. Judging from the influx of subscriptions from British sources since my return I assume that my visit suggested that now is a good time to begin the exchange of helpful information and that they want to be sure that the Americans are not the only ones to profit from it.

AMERICAN COAL MEN COULD EMULATE BRITISH

In most particulars the coal industry of England and Wales functions better than does the bituminous industry in the United States. While it is true that the production and distribution of coal there are not entirely comparable to those activities in the United States, it is apparent that there are many leaves we could take from the book of British practice and experience with great advantage to ourselves. This does not mean that the industry there does not have grave troubles, but some of the difficulties from which we suffer have been ironed out.

Car shortages practically are unknown. Mines never have to suspend operation for lack of cars. The longest period of idle time during the year is three days and that is to allow the workers their Easter holiday. There are few mines which work only one shift. It is true that the average haul in the British Isles is short, but there is careful co-operation of all concerned to

obtain a quick turn-over for the coal-carrying equipment. This keeps available a sufficient surplus of cars which can be used for storage purposes when ships are overdue or other delays develop. In addition, provision is made for some storage at the mine. There are instances where several days' output can be put on the ground near the pit mouth. This storage is arranged so that the cost of handling is kept at a minimum.

For a railroad to be given priority in the use of cars for hauling its own fuel is entirely unheard of. If there were stringency in car supply and were a railroad company to attempt to give a disproportionate number of cars to a mine with which it had contracts, it would cause a riot, to quote the words of M. W. Magee, an operator in the Newcastle region. No such attempt ever has been made and would not be brooked.

CONSIDER RESORT TO PRIORITY INEXCUSABLE

The railroads, a number of British operators told me, least of all should have to resort to such priority. They can conceive of a small enterprise, not in a position to hire engineers and skilled purchasing agents, failing to make adequate provision for an unexpected stoppage in its coal supplies. There would be some patience with a proposal that it be allowed some preference in obtaining an emergency delivery, but for a large concern like a railroad, methodically conducted and with staffs of engineers and technical men, to fail to have adequate storage at strategic points would be inexcusable. For a common carrier, on which the prosperity and even the health and comfort of the public depend, to be without large storage and to have to depend on priority and car supply is more than the British can understand.

Next to the adequate supply of railroad cars and motive power, the general practice on the part of consumers in storing coal is the most important factor contributing to the enviable stability of the British industry. It is an inherent trait in the British engineer and commercial administrator to provide very liberal margins of safety. Large stocks of coal are maintained by the railroads and most other consumers. Even the householder is less inclined to buy from hand to mouth or to wait until the last minute to lay in his fuel.

On a railroad, for instance, when stocks begin to decrease somewhat, the line comes into the market regardless of any prospect for lower prices. A certain reserve always is maintained. This varies with the locality, but no matter how unfavorable the market situation may be, stocks are not allowed to go below a definitely established point. The same policy is followed at gas works—consumers using a much larger portion of the output than in the United States. The British gas industry represents an investment of \$750,000,000. Other public utilities and manufacturing plants generally stock heavily. The same tendency ex-

ists among retailers. Large stocks are maintained throughout the year. This practice is regarded as being largely responsible for spreading the demand on the mines more or less evenly over the twelve months. There are certain peaks but the peak is much more likely to be caused by influences other than such seasonal demand as exists.

The profit-sharing wage unquestionably is another stabilizing factor. Much criticism of it is heard, but it emanates from an assertive minority. Labor is inclined to be critical of it, but it is noticeable at show-downs that it is amendment rather than abolition that the union wants. Some of the union leaders—leaders of the agitator class—see in the profit-sharing plan some menace to organization. They fear that some years hence the relationship will have become so standardized and will work so well that the principal benefit received from the union—periodic boosts of wage—will not be required. The more substantial of the labor leaders, however, recognize that there always will be impelling reasons for the men to maintain their organization.

In South Wales the operators, after more than thirty years of rather successful use of a sliding scale, based on the selling price of coal, were not inclined to give it up. Many of them still are outspoken in opposition to the new agreement. Nevertheless the opposition is passive and the real truth doubtless is that they are fairly well satisfied with the principle underlying the present arrangement.

In Northumberland and Durham, on the other hand, sentiment among the operators for the profit-sharing agreement is very strong. The mine worker no longer is wasteful, as he recognizes he is a greater loser than the mine owner. He does not throw away a prop, for instance. He saves it and uses it because five-sixths of the prop's value is his. Incidentally mine props there are more valuable than here. Supplies come from Nova Scotia and other distant sources. The miner does not load dirty coal because he realizes that most of the penalty will come out of his pocket.

Labor also is making some capital out of claims that the operators are concealing profits. In some instances, it is asserted, the operators also are interested in ships

and in brokerage companies. Because of those interests they are willing, some representatives of labor say, to sacrifice profit at the mine and recoup themselves from the profits made in further handling. In that way, it is maintained, labor loses its just share of profits. The contention hardly is sound, however, as labor is represented on the auditing committee, which has full access to each company's books. Any acceptance of prices out of line with costs would be detected immediately. There are some cases, of course, in which the operators of a mine also are interested financially in shipping, brokerage or coal-consuming enterprises. There may be some instances in which that fact influences to a slight extent the price at which the coal is sold. The tonnage to which this would apply, however, is negligible.

The objections to the profit-sharing plan apparently are diminishing as it is becoming better understood. Evidently it will survive and promises to become the greatest development of the last hundred years in industrial relations.

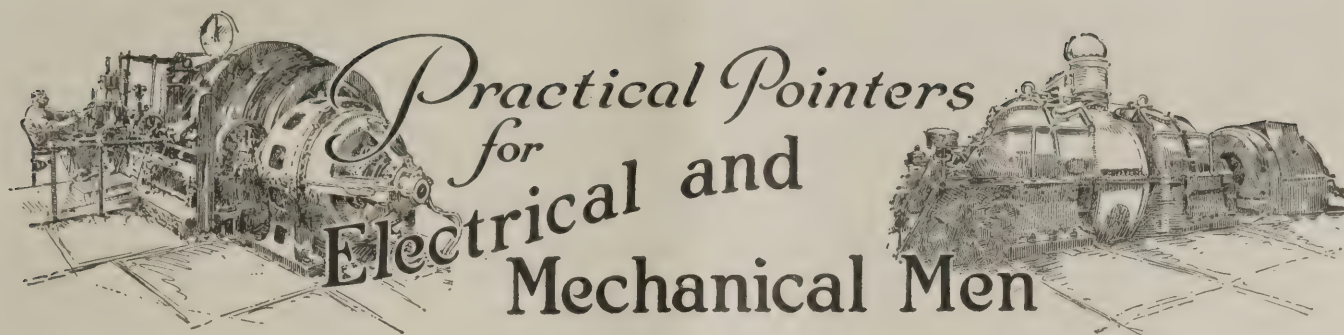

Next week Mr. Wooton compares the sliding scale with the profit-sharing wage plan now in vogue in Great Britain.

Officials Inspect No. 14 Colliery Pennsylvania Coal Co.

AT A RECENT visit of the officials of the Pennsylvania Coal Co. to No. 14 colliery, at Port Blanchard, the mine was closely inspected, the party being divided into five sections which visited every part of the operation. Each section had a leader who was charged with the duty of preparing a report on the part of the mine visited. A photograph was taken of the visiting party of fifty men in front of the colliery office. From this the accompanying illustration has been made. Special interest attaches to the inspection this year as the new steel and glass breaker, one of the most modern in the anthracite region, is just being completed. The steel work and glass are all in position, and finishing touches are being placed on the interior of the structure. The steel and glass exterior incloses not only the breaker proper but also the loading chutes.

OFFICIALS OF PENNSYLVANIA COAL CO. ON INSPECTION TRIP TO COLLIERY NO. 14

Reasons Why Power Generated at Mines May Be Inherently Uneconomic

REFERRING to the letter of Mr. Butcher, which appeared in the Nov. 22 issue of *Coal Age*, I would like to point out some inherent disadvantages of small and large degree which must be considered in a coal-mine power plant.

Mines having a daily output of 2,000 tons are rather common in the industry, but those having a daily output of 6,000 tons are extremely rare, and these, with few exceptions, are well equipped from every angle.

Actual practice has fully demonstrated the fact that central-station power is cheaper than power generated in a privately owned plant of the most modern character for the operation of a coal mine. The only objection to the use of electrical energy as supplied by public utilities has been the question of continuity of service, but this has been solved or is being worked out by the duplication of sources of supply.

Mixed-pressure turbines have been tried at coal mines but have not proved satisfactory as a general proposition, although in a few special cases they have given fair results over short periods of time. This does not condemn the mixed-pressure turbine, but does eliminate its use at coal mines.

Reliability and simplicity of steam consuming equipment at a coal mine is infinitely more important than high efficiency engines. In general, mining plants are of necessity so located as to render the use of condensing equipment of doubtful value in any case because of lack of sufficient water. In large underground steam-pumping stations the use of condensers may have value, but for other coal-mine applications they are not economical.

If it is necessary to operate a steam-driven ventilating fan at full speed over the entire 24-hour period, it is essential that the engine be in duplicate and of extremely rugged design with as few parts as possible, as reliability of operation is really the thing to be considered. The exhaust steam from such a fan would be available for an exhaust turbine if it were practicable to use it.

The steam used in hoisting engines is not available because of the relatively small amount used over the 24-hour period, the wide fluctuation in the load and the incidental cost of an installation that would permit its use.

The engines used to drive generators also produce a widely fluctuating load and the load factor of delivered energy usually is well below 20 per cent. It is, therefore, evident that this is no place for condensing equipment.

The present design of a steam plant at a coal mine

represents the best practice known for this particular class of service and is the result of many costly experiments and careful study. The factors that affect the design of a steam plant are load factor, life of plant and reliability of operation, as well as first cost and cost of operation. Because of the fact that a mine works only eight hours per day for 200 days per year, and in many cases less, the load factor is inherently low, usually being below 20 per cent.

Coal mining represents a constantly changing condition, with the result that the power requirements change from year to year and any arrangement becomes obsolete in a very few years. Because of the short life of the equipment, the increased first cost, as well as maintenance cost of so-called highly efficient equipment, its use is not warranted.

Because of the low load factor existing at coal mines and the demand for a flexible power supply to take care of the constantly changing conditions, central-station energy as supplied by public utilities can be purchased at a lower cost than power generated in a privately owned plant, serving one or two mines regardless of the design of the plant. This is not a theory but a fact based on the actual results obtained over a considerable period of time.

Pittsburgh, Pa.

CHARLES M. MEANS,
Consulting Engineer.

How Electricity Is Produced

ALTHOUGH we do not know what electricity is and we frequently hear it said that it is in its infancy, we know many facts about it. The laws governing its production, or, in other words its generation, what it does under certain circumstances, how to govern its action and how it may be applied to useful work, are all well defined. The feeling of mystery concerning electricity seems to be unwarranted. Steam has been in use for many years, yet there are certain aspects about steam and its application which are as mysterious as many things pertaining to electricity; in fact the laws governing electricity are more extensively known and

ILLUSTRATION OF DIRECT AND ALTERNATING CURRENT

At A the current is continually flowing from left to right, as indicated by the arrow, and represents direct current. At B₁ the current flows from left to right for only a short interval of time. B₂ shows the same wire as at B₁ but at another instant, showing that the current is now flowing in an opposite direction. This change of direction of current alternates; hence it is distinguished from direct current by being called alternating current.

understood by scientists than the laws of steam. The word electricity comes from the Greek word amber, and its development has come from the fact that the Greeks discovered that when amber was rubbed it had a property that caused it to attract light bodies. Later this attractive force possessed by rubbed amber was found to be a form of electricity.

There are several different forms of electricity and several ways of producing it. Two common forms in which we find electricity are static or frictional and current electricity. The three most common methods of producing it are by friction, chemical action, and by induction.

HOW TO PRODUCE ELECTRICITY

Static electricity is generated by friction. Rubbing a stick of sealing wax and a piece of flannel or a glass rod and a piece of silk will produce static or frictional electricity. It may also be produced by a comb rubbed in the hair, stroking cat's fur or by a person rubbing his feet over a carpet. When electricity is formed by any of these methods one of the two different substances becomes charged with what we call positive electricity and the other with negative electricity. These two charges attract each other while bodies charged with like electricity repel each other. This establishes a general law which may be stated as follows: Bodies charged with like electricity repel each other, and bodies charged with unlike electricity attract each other. The uses of electricity in the static form are not of great practical importance, except at high voltages. Lightning is a form of static or frictional electricity of very high voltage.

Current electricity, as we have stated before, is generated by chemical means or by means of induction. Electricity is generated by chemical means in what is called a voltaic cell. Inside the cell a chemical action takes place which releases the chemical energy in the form of electrical energy. Electricity generated by chemical means is unidirectional and is called direct current.

Electricity produced by induction usually is generated in a machine called a generator or alternator. When generated by induction it may be direct current or alternating current. It is generally understood that direct current is generated in what is called the generator and alternating current is generated in what is called an alternator. Alternating current is one which reverses in the direction of its flow a number of times per second. An alternating current which reverses its direction 120 times per second is called 60-cycle alternating current.

CYCLE OF ALTERNATING CURRENT

A cycle is two alternations. Obviously the more rapid the alternations or changes of direction of current in the wire carrying alternating current the larger the number of cycles per second. Ordinary power and lighting circuits operating on alternating-current electricity are supplied with current of 60 cycles. The number of cycles per second is known as the frequency of the alternating current. High-frequency alternating current has several commercial applications; in radio telephony alternating current of 1,000,000 cycles per second is common. It is the frequency of the transmission voltage which determines what is known as the wave length of a sending station.

To visualize direct and alternating current we may

think of water in a water pipe. If this water is flowing in one direction continually it represents what is understood as direct-current electricity. If the water alternates in the direction of flow it represents what is known as alternating current.

Advantages of Purchased Power

THERE is still much discussion at many coal-mining properties on the subject of purchased power versus power made at the mines and therefore I wish to present a few of the advantages of purchased power to the readers of *Coal Age*.

Wherever purchased power is available it usually will be found to be more economical for the mine operator to purchase power for his use, because of its reliability and ultimate low cost.

How many times a year does purchased power prove itself the more reliable? With power generated at the mine a serious burn-out of electrical generating equipment or a breakdown of some of the other machinery in the power house will frequently mean long and costly delays. With purchased power it is nearly always possible to resort to spare equipment located in the power house when such emergencies arise.

Purchased power usually is cheaper for the operator because it does away with the necessity for experienced power-plant attendants, which always are necessary where power is generated at low cost. Then again, the power bill of the power company is not a complete item of expense to the operator because he must credit himself with the additional amount of fuel he is placing upon the market since he is buying his power instead of making it himself. A mine often is located where water must be pumped a considerable distance for the boilers, which means a large item of expense to the operator making his own power.

Many times the mine operator will have to install transforming equipment for reducing the delivery voltage of the power company to his requirements, but rarely does this equipment cost a great deal; in fact, many such substations are frequently installed by the power company and charged off to the mine operator as small monthly payments included in his power bill.

Apparently purchased power has many advantages which are of interest to the small and large mine operator.

Electrical Engineer.

PROFIT SHARING AT BRITISH MINES.—An interesting sociological development in the coal-mining industry of Great Britain, whereby the mine owners and the miners share in the distribution of profits, is reported by George S. Rice, chief mining engineer, U. S. Bureau of Mines. Under this plan the mines are grouped in districts and monthly, in each designated district, the gross expenses of production of the coal are deducted from the gross profits of the mines of that district, and from this gross net profit 6 per cent of the invested capital is deducted, the remainder, if any, being divided between the owners and miners, the owners receiving 17½ per cent and the miners 82½ per cent. The miners' share, if any, is pro-rated among the miners of the district, and the sum thus determined by certified accountants is paid to the miners two months later in the form of an increase in wages.

New Equipment

A Small Screen with Large Capacity

GRAVITY screens must be built long or they are ineffectual. The shaking screen has a greater capacity per square foot and is more efficient than the gravity-operated unit, but the vibrating screens are said to exceed both, not only passing a greater tonnage per unit of screen area but making also a more complete separation of fines. The main difficulty is with wet material.

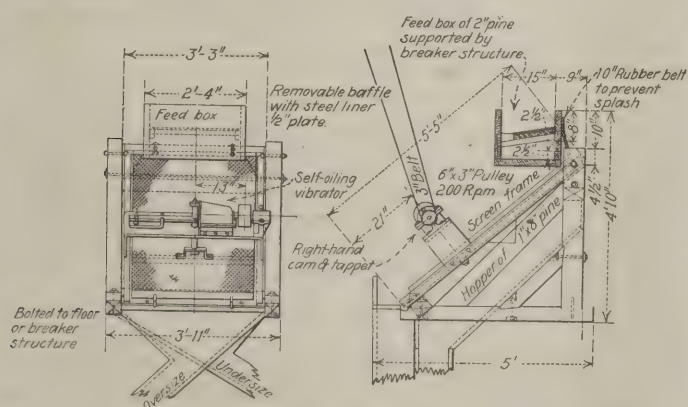

A screen that is said to have given excellent service with both wet and dry fines is the Leahy No-Blind Screen of the Deister Concentrator Co., Fort Wayne,

SCREEN THAT CLEANS ITS OWN MESHES

Constant vibration of the screen keeps the material from building up in the opening and changing the screen into a mere chute, as too often happens with a screen which operates only by gravity or with the aid of shaking mechanism.

Ind. It is said to give a quick return differential vibration that is transmitted to the entire surface of the screen cloth so that the particles are screened and stratified according to their relative masses, and the finer particles pass through the screen without hindrance by those which are oversize.

SCREEN AS INSTALLED IN TIPPLE OR BREAKER

It is only 5 ft. 5 in. long and its projected length is less than 5 ft. so that a real economy of space is attained.

The anvil action at the end of each quick return stroke clears the meshes of the screen cloth so that the screen is non-blinding under all conditions of feed. The vibrator runs in oil and has only two wearing parts. The screen is driven by a 3-in. belt and requires $\frac{1}{4}$ to $\frac{1}{2}$ hp. A single spring adjustment controls the intensity of vibration and adjusts it to suit the load and the material being screened. The screen cloth is held in longitudinal tension by two bolts and can be changed in five minutes time. Any wire-mesh screen cloth may be used. With the vibrator driven at 200 r.p.m. 1,600 quick-return differential vibrations are transmitted directly to the screen cloth. The normal amplitude of the screen vibration is $\frac{1}{16}$ in. directly under the vibrator.

Safety Grease Lubricator

THE Keystone manifold safety lubricator presents a method of applying grease under high pressure with pipe-line distribution to more than one bearing. It accomplishes this result without risk to the operator or waste of grease.

Bearings that are difficult of access due to small clearances between working parts, heat and other unfavorable conditions, are made easy to reach by this medium of lubrication, thus insuring the proper lubrication of bearings that otherwise might be neglected because of inconvenience and hazardous conditions.

Heavy flexible metallic tubing is frequently used for the leads from the manifold to machinery bearings. By means of valves on each outlet the lubrication of any bearing may be regulated. In some instances valves may be permanently adjusted to allow the grease to flow in uniform quantities to all the bearings whenever the lubricator is operated.

This lubricator is designed not only from a standpoint of economy but to safeguard employees while oiling and

LOCOMOTIVE WITH MANIFOLD LUBRICATOR

Flexible pipe lines leading from the manifold to all the bearings insure proper lubrication at all times. Merely turning the handle with the valves open forces grease to any desired location on the locomotive.

greasing machinery where there may be an element of risk in the work.

For mining machinery this device has many applications, especially on hoisting and locomotive equipment, which is difficult and hazardous to lubricate. Proper lubrication of equipment will thus avoid serious breakdown delays, accidents and waste.

The complete outfit is sold by the Keystone Lubricating Co. of Philadelphia, Pa.

Working Three Contiguous Seams With Rock Partings

Proposed Plan Impracticable—Insufficient Space to Store Waste Material—Another Plan Described That Has Given Success

HAVING had some experience in working contiguous seams of coal separated by rock partings of varying thickness, it has been with much interest that I have followed the discussion started by the inquiry that appeared in *Coal Age*, Aug. 9, p. 219. Following is the section of the strata described in this inquiry:

Starting from a footwall of hard sandy shale, a 12-in. seam of clean coal is overlaid with 2 ft. of hard slate parting, which separates it from 3 ft. of hard splint coal forming the middle seam. Another parting of hard sandy shale from 4 to 6 ft. in thickness separates the middle seam from the upper coal, which is 3½ ft. in thickness. This top coal is overlaid with a hard sandstone roof.

Kindly permit me to offer a friendly criticism of the plan proposed by the inquirer and which he regards as promising a successful method of working these three seams, with a view to securing a high percentage of production and a good marketable condition of the coal. Following that, I want to describe a plan that appeals to me as certain of meeting every requirement, including safety and economy of working.

WHY PROPOSED PLAN IS IMPRACTICABLE

In the first place, the proposed driving of double or triple rooms, from 60 to 90 ft. in width, between a sandrock roof and a hard shale footwall is, to my mind, impracticable. To drive rooms 90 ft. wide separated by

FIG. 1—GENERAL PLAN, SHOWING DOUBLE 50-FT. ROOMS

50-ft. pillars of hard splint coal would tend to produce a creep. Or, driving 60-ft. double rooms with the same pillars between them and, brushing the two roadways to the footwall, each 10 ft. wide, would not provide sufficient space for gobbing the rock between these roads.

Even if the rock is packed with the utmost care, it will be found that there will not be room to hold the waste rock. Moreover, only 33½ per cent of the bottom coal will be recovered at a great expense of labor; and,

50-ft. pillars of hard splint coal would tend to produce a creep. Or, driving 60-ft. double rooms with the same pillars between them and, brushing the two roadways to the footwall, each 10 ft. wide, would not provide sufficient space for gobbing the rock between these roads.

Allowing the ratio of rock in the solid to rock broken

in my opinion, it will be impossible to work the top coal at all by this method.

Briefly described, my plan would be to abandon entirely the idea of mining the bottom seam, except for the coal taken out in the headings and roomnecks. As shown in Fig. 1, I would drive double rooms 50 ft. wide with 60-ft. pillars between them. Driving the roomnecks 10 ft. wide for a distance of 10 yd., leaves a pillar 30 ft. square in the neck of each room. The crosscuts in the room pillars are driven on 60-ft. centers.

DEVELOPMENT STARTED IN MIDDLE SEAM

The rooms are driven in the middle seam. The main and cross-entries are driven 10 ft. wide and 6 ft. high, the lower parting and the bottom seam of coal being taken up on these entries and the rock loaded out. The rooms are driven up from 200 to 250 ft. and well timbered, as indicated in Fig. 2, in the plan on the left.

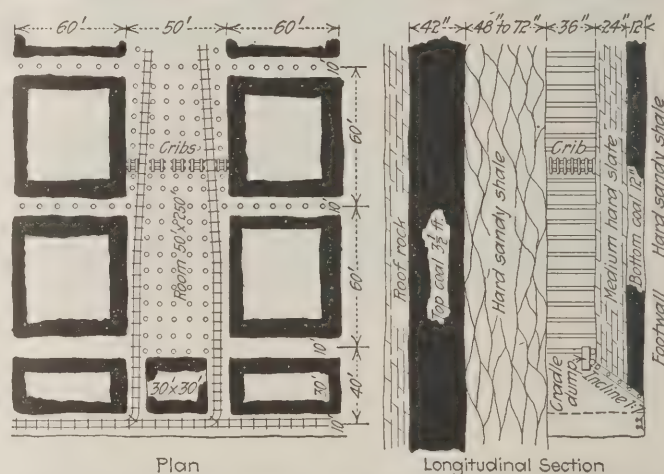

FIG. 2—PLAN AND ELEVATION WORKING MIDDLE SEAM

As shown in the elevation on the right of Fig. 2, starting a short distance inside of each roomneck, an incline pitching about 1 in. 7 is driven up to the middle seam. A special low car is used holding about one ton. Two men can readily push this car up the incline when the room is being worked in the middle seam.

PLAN TO REACH THE TOP COAL

At a point about halfway of the length of the room, is now placed a row of good cribs to take the weight and prevent the rock from riding over all the props when it is desired to get the first fall. The plan is, later, to pull the props in regular order, starting from the cribs and continuing back to the roomneck, allowing the parting rock to fall and probably the top coal above it.

As each room is driven up the required distance and the coal taken out, the track and ties are removed. The use of steel ties gives several inches of much desired

headroom and both the ties and track are more easily removed. When this has been done, the work of pulling the props between the cribs and the roomnecks is begun.

Should it happen that the rock fails to fall when this method is tried in the first room, a row of shotholes must be drilled along each rib. A pillar of solid coal 100 ft. wide separates the first room from the main headings for their protection. A good fall should be made in the first room, before the same is attempted in the room next adjoining. Experience will be a guide to future procedure.

BUGGY USED TO LOAD OUT TOP COAL

After getting a good fall, the crosscuts are choked up to the cribs and it is now necessary to drive two chutes, one in each roomneck, up to the top coal, as shown in Fig. 3, which illustrates the condition after

FIG. 3—PLAN AND ELEVATION WORKING OUT TOP COAL

the first fall has taken place as far back as the cribs. A low buggy is used for loading out this coal, the buggy being dumped over a small cradle dump arranged at the top of each chute. The coal falls directly into the mine car standing under the chute. If desired, a door can be arranged to control the descent of the coal, as in a regular loading chute.

Light-weight track is laid from the cradle-dump and sheetiron plates are used to turn the buggies along the face in loading out the top coal. These plates are easily moved forward when necessary. As the work advances, cribs are built to support the roof and protect the track, which must be used to bring back the top-coal pillars.

IDEAL METHOD FOR RETREATING PLAN

The falls in the second and succeeding rooms are produced in the same manner as just described, using the crosscuts as escapeways, in case a hasty retreat becomes necessary. When the cross-entries have reached their distance, the entry pillars are pulled by driving 20-ft. rooms through the center of each pillar, thereby leaving 20-ft. pillars on either side. These pillars are pulled from the inby end to the next outby crosscut, allowing the overhead parting rock and top coal to fall. This top coal is then loaded from the two adjoining rooms, using the track nearest to the pillar and dumping the coal through the chutes.

To my mind, this is an ideal system for driving the entries to their destination or boundary, before working the rooms. If that is done, both the wide and the

narrow rooms can be worked at the same time, starting from the inby end. As soon as the last of the top coal is loaded out of the rooms, the narrow room can be ready for its first fall. The top coal may then be loaded continuously, until both the room and the pillar are loaded out. Moreover, there will be less danger from the cribs in the top seam rotting away while waiting for the pillars to be pulled back, and there will be no danger from creep.

In the use of this method, it is quite evident that there is very little shooting required to mine the top coal, whether it falls with the parting or holds fast to the roof. As a result, a maximum of lump coal will be produced and a good output obtained, per man, per day. There is not as much danger in pulling the props as would seem.

For two years, I was foreman at a mine working two seams of coal separated by from 12 to 36 in. of slate. The bottom seam ran from 3 ft. to 6 ft. in thickness, while the top seam averaged 3 ft. The coal was overlaid with stratified sandrock. We employed the system just described and I never knew a man to meet with an accident in pulling the props for a fall. Any of the experienced men would "throw in" a room 20 ft. wide, for a distance of from 75 to 100 ft., for \$3. This was in 1917.

Resistance to Flow of Air Offered by Obstructions in Airway

Investigation underway to determine amount of resistance offered by different forms of obstruction—Important to provide for stream-line movement of air current.

IT WAS with much pleasure that I noticed the reference to "Reducing Resistance to Flow of Air in Fan-shaft," which appeared in *Coal Age*, Oct. 11, p. 561. The inquirer desired information in regard to the benefit to be derived by rounding the bottom of the fan shaft so as to avoid abutting surfaces for the air current to strike against.

It was also stated that 40-lb. steel rails had been placed across the shaft to resist the pressure due to a quicksand formation a few feet below the surface. The question was asked to what extent these rails would obstruct the flow of the air in the shaft.

Inasmuch as the investigations in my charge at the present time have for their object the determination of the resistance offered by different forms of obstruction to the flow of air in airways, I was deeply interested in reading the reply of the editor to this inquiry.

INVESTIGATIONS TO DETERMINE THE RESISTANCE OFFERED BY TURN IN AIRWAY

In general, the resistance offered by a right angle turn in an airway, such as is met at the foot of a shaft, has been found to cause a theoretical loss of pressure equal to twice the velocity head of the current, as the editor has stated in reference to the effect that may be expected to result from rounding the bottom of the shaft. This was one of the first results shown in our investigations, which are just beginning to get underway. Later, we expect to be able to specifically evaluate the various forms of obstructions commonly found in airways.

Regarding the resistance offered by the steel rails

described as placed across the shaft, it is quite probable that their effect is greater than may be generally supposed. While we are unable, at this time, to present any precise numerical data on this form of obstruction, it can be said that some work which has been done indicates that the loss of pressure due to the air current striking such an obstruction at a high velocity is considerable, I may even say surprisingly large.

STREAM-LINE CURRENT REDUCES RESISTANCE

In my opinion, such losses may be cut down to one-half or even one-fourth by giving the crossbeams a fish shape that will divide the air current and cause it to follow stream lines, instead of creating an eddy just beyond the obstruction. Let me suggest, therefore, that much benefit would be derived, in this case, by building up a shell about the rails placed in the shaft, so as to give them a stream line effect.

Using light sheet metal, a good mechanic can do this at a comparatively small cost. Or, possibly, the rails can be encased in concrete so as to present the same stream-line shape to the air current. The exact position of these rails in the shaft is not given in the inquiry further than to say that they are placed across the shaft. I have shown, in the accompanying sketch, how these

may be encased in sheet metal, or concrete, to produce the desired effect and very much reduce their resistance to the flow of the air.

In view of the investigations in progress along this line, it might be a benefit both to the operator and to ourselves engaged in the work, if arrangements could

CREATING STREAM LINES PAST OBSTRUCTING RAILS

be made to take some readings in this shaft, for the purpose of determining the pressure losses resulting from the obstruction offered by the rails. We would be glad to take such readings, both before and after the suggested changes are made, if that is done. For that work, we have developed some precise sensitive instruments for measuring such pressure differences.

Inquiries Of General Interest

Weight and Expansion of Water, Formulas for Calculating

*Temperature of Water at Maximum Density—
Coefficient Shows Expansion Is Then Zero—
Maximum Density Basis of Calculation*

KINDLY give the weight of a gallon of pure water and state whether this weight per gallon is the same for all temperatures. If not, how can the weight be estimated for any given temperature?

Denver, Colo.

STUDENT.

For ordinary calculations, the weight of pure water is commonly taken as 62.5 lb. per cu.ft., or $62.5 \times 231/1,728 =$ say 8½ lb. per gal., making 12 gallons per hundred pounds of water. For closer calculation, however, the weight of pure water, at maximum density (39.2 deg. F.), is 62.4283 lb. per cu.ft., or 8.345 lb. per gal.

Owing to a very slight expansion of the water by heat, its density and weight, per unit volume, is slightly less at the higher temperatures. In order to calculate the weight of any given volume of water at a given temperature, it is necessary to multiply the weight of the water at maximum density, by its density at the given temperature. For example, the density, (*D*) of pure water, at any temperature (*T*, absolute), is given very approximately by the formula,

$$D = \frac{1,000 T}{500^2 + T^2}$$

This formula is based on a density of unity, or 1, at

the temperature of maximum density of the water. In the calculations, all the temperatures are absolute temperatures making that of maximum density 460 + 39.2 = say 500.

CALCULATING THE COEFFICIENT OF EXPANSION

As stated previously, the expansion of water, for any given rise in temperature, is very slight. The coefficient of expansion for any given temperature, may be calculated thus: Since the formula just given expresses the density of pure water at an absolute temperature *T*, its volume per pound at such temperature, is the reciprocal of that formula, which gives

$$\text{Vol. per lb.} = \frac{500^2 + T^2}{1,000 T}$$

Then, taking the volume at maximum density as unity, or 1, the increase in volume, at any temperature *T*, absolute, is

$$\frac{500^2 + T^2}{1,000 T} - 1 = \frac{500^2 + T^2 - 1,000 T}{1,000 T} = \frac{(T - 500)^2}{1,000 T}$$

The original volume at maximum density being 1, this increase in volume, at any temperature *T*, gives the ratio of expansion for such rise in temperature. Finally, dividing again by the temperature, absolute, gives for the average expansion per degree, or approximate coefficient of expansion.

$$\text{Coef. of expansion} = \frac{(T - 500)^2}{1,000 T^2}$$

Notice that the expansion at maximum density becomes zero, since then *T* = 500. By way of illustration, let it be required to find the volume of 1,000 cu.ft. of pure water at a temperature of, say 240 deg. F. (460 + 240 = 700 deg. abs.). The coefficient of expansion of the water at the given temperature being

$$\text{Coef. of expansion} = \frac{(700 - 500)^2}{1,000 \times 700^2} = 0.00008$$

which makes the increase in this volume 1,000 × 0.00008 = 0.08 cu.ft., which is so slight as to be practically inappreciable.

Examination Questions Answered

Anthracite Foremen's Examination, Districts 15 and 16, 1923

(Selected Questions)

QUESTION—*Why is it that firedamp may be found and ignited near the roof of a mine when there is none near the bottom; and why does blackdamp seek the lower level?*

ANSWER—Firedamp is an explosive or an inflammable mixture of methane (marsh gas) and air. The specific gravity of methane is 0.559, showing it to be little more than half again as heavy as air. On this account, the firedamp mixture is always lighter than air and has a tendency to accumulate at the roof and at other high points in the mine.

On the other hand, blackdamp is a mixture of carbon dioxide and air. The specific gravity of carbon dioxide is 1.529, showing blackdamp to be more than half again as heavy as air. On this account, a blackdamp mixture tends to accumulate at the floor or in other low places in the mine.

QUESTION—*If two breasts are being driven toward each other what precaution would you take to prevent accidents from blasting?*

ANSWER—The utmost care must be taken, in such cases, to give ample warning before proceeding to fire a shot in either place. One must be sure that the warning is understood by the response given to the signals indicating that a shot is about to be fired. When the breasts have approached each other closely and but a few feet of barrier coal remains the safest plan is to stop the men working in one of the places till the shots have holed through.

QUESTION—*If you were acting as assistant mine foreman, where would you consider the proper place to leave your ordinary mine lamp when making the early examination of the section of the mine you have in charge?*

ANSWER—When making his early examination in the morning a fireboss should never carry an open light into the section of the mine in his charge. He should have with him none but an approved safety lamp that has been duly examined, cleaned and assembled, except he may carry an electric cap lamp to give him the best possible light in examining the roof, coal and timbers at the working faces. If an open light is taken at all into the mine it should be left on the shaft bottom.

QUESTION—*Why is the ignition of a small body of firedamp more dangerous in a thin seam of coal than in a thick seam? State fully.*

ANSWER—When a body of gas is ignited in a thin seam or contracted openings the expansion of the hot gases causes the flame to practically fill the opening and there is little escape for the men who may be present. On the other hand, in a thicker seam where there is ample headroom, the flame of the igniting gas will often travel along the roof, thereby affording greater opportunity for the men to escape.

QUESTION—*How would you proceed to remove a body*

of firedamp from a series of breasts, pitching 30 deg., the gas having accumulated during the stopping of the fan?

ANSWER—Before making any attempt to remove or disturb the gas, notify and withdraw all the men working in that section or exposed to the return current in its passage out of the mine. Then, starting at the outby end on the intake side of the section, deflect all the air toward the face of the first place, by erecting a brattice or hanging a canvas for that purpose in the entry. Allow none but experienced men to assist in the work and use none but approved safety lamps that have been carefully examined and assembled.

Proceed slowly, allowing plenty of time for the air to sweep away the gases accumulated at the face of the pitch, in the first chamber. Make frequent tests with a safety lamp to ascertain the progress of the work. When the first chamber is clear of gas, carry the brattice through the last crosscut and extend it so as to sweep the gas from that place. In like manner, continue to clear each place of gas throughout the section. The entire section must then be carefully examined and reported safe before men are permitted to enter again for work.

QUESTION—*What care and attention should safety lamps receive if used in a mine giving off considerable gas? Who does the law require to furnish and care for the safety lamps?*

ANSWER—The Anthracite Mining Law, Art. 12, Rule 9, requires the employment of a competent person charged with the duty of examining every safety lamp immediately before it is taken into the workings for use. All lamps must be clean, safe and securely locked before being given to the men, except when the mine foreman permits a lamp to be used unlocked, which he is authorized to do. The same section provides that the lamps shall be the property of the owner of the mine.

QUESTION—*Explain the difference between natural and mechanical ventilation and state which, in your opinion, is the most dependable, giving your reasons in full.*

ANSWER—Natural ventilation depends on the circulation of air through the operation of a natural agency, such as the natural heat of the mine; the force of surface winds acting on the mine opening; or the action of water falling in a shaft. The natural heat of the mine forms an air column in a shaft or a slope mine and in rise and dip workings. The resulting pressure is determined by the difference in temperature of the inside and outside air and height of the air column.

On the other hand, mechanical ventilation is that produced by mechanical means, as the action of a fan, steam jet or blower. Mechanical ventilation is more dependable than any form of natural ventilation, being under better control and capable of being increased according to requirements.

QUESTION—*Why is the ventilation of a mine necessary? Describe fully.*

ANSWER—Ventilation is necessary in order to remove all noxious gas generated in a mine and supply in its place fresh air that will support life and make the mine safe for work. The air current entering the mine dilutes and renders harmless the inflammable and poisonous gases that may be produced and which render the mine unsafe for work. When properly conducted the force of the air current sweeps these gases from their lodgments and carries them out of the mine.

High Spots in U. S. Coal Commission's Report On Bituminous Miners and Their Homes

The Coal Commission made a study of original census returns for 1920. It found:

Soft-coal mine workers numbered 584,985 and 147,456 were anthracite workers.

Twenty-one per cent of soft-coal workers live in towns of 2,500 or more, 79 per cent live in the country.

Nearly 60 per cent are native-born white, 8.1 are native colored, and 32.7 were born outside the United States.

Sixty-nine per cent of the foreign-born bituminous-mine workers have been in this country 10 years or more; of anthracite workers 78 per cent.

Eighty-eight per cent of soft-coal workers are able to read and write.

Over 62 per cent maintain homes where they work, and over 95 per cent of these are or have been married men.

Nearly 11 per cent of the soft-coal mine workers are sons of mine workers.

Approximately half the soft-coal mine workers live in company owned houses.

The report lists 66 "best" company controlled mining towns out of 713 examined, and 82 "worst."

This report represents "three distinct but related field investigations and a tabulation of census data hitherto unutilized." Field agents made surveys of 880 communities—713 controlled by companies, 167 independents—for data on physical environment and community resources; sanitary surveys were made for the Commission by the U. S. Public Health Service in 123 communities, 64 company controlled and 59 independent, and retail prices, rental rates, etc., were studied in selected districts and family budgets collected for information about the cost of living.

Pinchot Inspection Plan Maintains Quality of Anthracite

The State Department of Mines of Pennsylvania has received the first reports of the inspection made by order of Governor Pinchot to ascertain what quality of coal is being furnished the public by the anthracite producers. These show that stone and bone were found in a number of cars of domestic sizes of coal, and that the coal was below the required standard. The coal was condemned.

A statement issued by the department reads:

"An important part in Governor Pinchot's plan to correct the abuses in the anthracite industry of Pennsylvania is the improvement in the quality of coal furnished to consumers. This is one of the most deplorable phases of the situation, as coal of inferior quality means a decided increase in the actual cost to the consumer. Among the reputable operators there is a standard of quality and when it is adhered to no complaint is made regarding the quality of the coal. This standard, roughly speaking, allows the following percentages of unburnable matter: In broken or grate coal, 1 per cent slate and 1 per cent bone; egg, 2 per cent slate, 2 per cent bone; stove, 4 per cent slate, 3 per cent bone; chestnut, 6 per cent slate, 5 per cent bone, and in the very small steam sizes from 10 to 20 per cent slate and bone.

"To get first-hand information on this subject and to accomplish immediate results for the benefit of the public the Governor directed Secretary Walsh, of the Department of Mines, to take charge of the matter. Secretary Walsh last week issued instructions to the state mine inspectors in the anthracite region to go to the mines and inspect the coal that was loaded for shipment to market. Reports have not yet been received from all of the inspectors, but those that have been received show the wisdom of the course being pursued to obtain clean coal, and the effect upon future shipments no doubt will be such as to guarantee a very much better grade of coal in many instances than has been furnished in the past."

Mining Institute Nominates Officers

William Kelly, of Vulcan, Mich., mining engineer and industrialist, has been nominated as president of the American Institute of Mining and Metallurgical Engineers for 1924. As vice-presidents and directors, Everette L. DeGolyer, geologist, of New York City, and Charles W. Merrill, metallurgist, of San Francisco, were named. Directors were selected as follows: R. V. Norris, engineer, of Wilkes-Barre, Pa.; George Otis Smith, of Washington, director of

the U. S. Geological Survey; P. B. Butler, mine operator, of Joplin, Mo.; B. D. Quarrie, steel manager, of Cleveland, Ohio, and L. D. Ricketts, engineer, of Warren, Ariz. The nominating committee was composed of Raymond Guyer, chairman; Stuart Crossdale, L. H. Duschak, Carle R. Hayward, Sidney J. Jennings, Birch O. Mahaffey and Dwight E. Woodbridge.

The annual meeting of the Institute will be held in New York City Feb. 18, 19, 20 and 21.

Keeney Proposes Unionizing West Virginia

That the United Mine Workers of West Virginia propose to organize all the miners in the state if possible, is the gist of a statement just made by C. F. Keeney, president of district 17, United Mine Workers, under whose jurisdiction comes all the organized miners of the state at the present time. Coupled with the statement is a general invitation extended to the unorganized coal miners to become identified with the union.

The district president in issuing the invitation declares that "all lawful assistance and moral support" will be extended those desiring to accept the union invitation. He states that the international organization and all its financial resources are back of the campaign to organize non-union fields. Not only is the announcement of the president of district 17 considered significant coming as it does on the heels of the meeting of the policy committee of the union at Cincinnati, but the statement made by Keeney even hints that the announcement is a result of the Indianapolis policy meeting.

2 Dead, 13 Injured in Orient Mine Blast

Two miners were killed and thirteen injured in an explosion in the No. 1 mine of the Chicago, Wilmington & Franklin Coal Co., at Orient, Ill., on the morning of Nov. 26, according to a press dispatch. Six of the injured, it is said, are likely to die. Thirty-five men were working in the section affected by the blast, all of whom had been brought to the surface by the rescue teams at 1 p.m. The big mine employs more than 1,000 men, 922 of whom were in the mine when the explosion occurred. A greater disaster probably was averted by the company's disposition of air currents, which confined the effects of the blast to a small area.

WASHINGTON, Nov. 25.—A pure-coal bill, to follow as nearly as possible the form of the pure-food law, is to be introduced by Senator Borah on the convening of Congress.

Urges Regulation of Anthracite From Mine to Retailer

Governors Asked to Make Concerted Move to Insure Public "Honest Coal at Decent Price"

Governor Pinchot of Pennsylvania opened his anthracite conference in Harrisburg on Monday, Nov. 26, with an appeal to the governors and their representatives from anthracite-consuming states to join with him in a concerted effort to put the anthracite industry from mine to retailer under state and federal regulation.

"The anthracite-using people of America are justly entitled to three things. The first is coal. The second is honest coal. The third is honest coal at a decent price." With these words the Governor opened his address. He said that the settlement of the recent strike provided coal but it could not assure relief from impure coal, nor could it assure freedom from extortionate prices. He said that no other question holds the attention of the people like this question of "honest coal at a decent price and that upon no other question will consumers of anthracite demand such an accounting from executive and legislative authority," adding, "there is no more certain way of incurring their resentment than by failing to take the necessary steps."

There is a tendency, the Governor said, among conservative business men and conservative journals "to consider the government's taking over the anthracite mines, if justice can be had no other way. The public feeling is so deep," he said, "because the people know the anthracite business is a monopoly—greedy, relentless, defiant." Anthracite is a necessity in the control of a monopoly and therefore the anthracite industry is affected with a public interest, and, being a monopoly affected with a public interest, "according to the Supreme Court, is a proper subject for government control."

SAYS OPERATORS TOOK UNFAIR ADVANTAGE

Charging that the settlement of the strike put the wages of the miners only where they should be, increasing production cost 60c. per ton, the Governor charged that the operators "not only passed the whole increase over to the public, which was thoroughly unjust, but took advantage of the situation to make their own profit greater than before." He reiterated his opinion, expressed at Philadelphia two weeks ago, that the whole combination is a "hard-boiled monopoly whose prime interest in the public is that it shall consume their coal at their price."

He stated that the first thing to do is for the state executives to use the power they now have, as by publicity as to fraudulent practices. State officials also can "ascertain and tell the people what extortions are being practiced, and by whom." Discussing Pennsylvania's share, the Governor said that he had already vigorously attacked the problem of rock and dirt in anthracite and is making public the names of operators who are guilty. Royalties, he said, are matters of private contract and cannot be changed. He defended the certification of miners and said that "nothing could be more foolish than to open the anthracite mines to unskilled mining." The certification law is a just and proper one, he said; "It should not be repealed."

The Pennsylvania anthracite tax has no effect on the price of coal, and Governor Pinchot stated that he was emphatically against its repeal.

Federal action was urged because nine-tenths of the anthracite moves in interstate traffic. Standards for clean coal and for sizes in interstate commerce in anthracite, licenses for all who engage in the trade and authority for denial of railroad cars were three things, together with publicity of accounts, that Governor Pinchot recommended particularly.

Whatever doubt there may be as to the right of the United States "to fix prices, establish uniform accounts, examine books, or require reports in the anthracite industry," Governor Pinchot pointed out that each state can do all of these things if it chooses. He suggested that the

"treaty or compact between the states authorized by the federal Constitution" be seized upon by the anthracite-consuming states as authority under which to set up a joint commission and agree upon a form of regulation of the anthracite industry.

He called for a committee of the governors to prepare a draft for federal legislation and to draft a form of compact to utilize state powers, "with a view to immediate action."

Anthracite Margins Continue to Shrink, Says Federal Trade Commission

Margins taken by anthracite wholesalers have steadily declined since the anthracite strike in September, the Federal Trade Commission reported Nov. 26. There also has been a sharp decrease in the proportion of sales at premium prices. Heavy production at the mines, the commission said, probably is chiefly responsible for the falling off in such sales, but the publication of facts concerning profits and prices has also helped to "bring about a return to normal."

In the first week after the strike the commission found as much as 66 per cent of the coal handled by wholesalers had a profit margin of more than 50c. a ton put upon it. In the week of Nov. 13, the last for which figures were assembled, about 34 per cent was sold at a 50c. wholesale margin.

During the two weeks ending Sept. 22 as much as 30 per cent of the coal traded through wholesalers' hands had cost more than \$12 a ton at the mines. During a like period ending Nov. 3, only 18 per cent of the coal traced had been sold at so high a price.

The commission said that all during the period of investigation "the railroad" anthracite producers, which control most of the tonnage, had sold their output at from \$8.75 to \$9.25 a ton at the mines.

"For the two weeks ending Nov. 3, as compared with the two preceding weeks," says the commission's latest report, "there was no change in the proportion of domestic sizes of anthracite passing through the hands of two or more wholesalers. During the six weeks ending Nov. 3, approximately 25 per cent of all sales reported passed through the hands of two or more wholesalers. For premium domestic sizes reported by wholesalers for the two weeks ending Nov. 3, 74 per cent passed through the hands of but one wholesaler; 25 per cent passed through the hands of at least two wholesalers, and only 1 per cent passed through the hands of at least three wholesalers. For steam sizes the percentages are quite different; 42 per cent passed through the hands of one wholesaler; 57 per cent passed through the hands of at least three wholesalers."

Jackson-Walker and Midland Coal Cos.

Merge; Each Retains Old Name

A merger of the Jackson-Walker Coal & Mining Co. and the Midland Coal Co. was announced in Kansas City, Nov. 20. The merger was effected by an exchange of stock by C. P. A. Clough, principal owner and president of the Jackson-Walker company, and C. H. Markham and H. G. Kellogg, owners of the Midland. The two firms will retain their individual names, but will occupy joint offices, probably those of the Jackson-Walker company, in Kansas City.

The Jackson-Walker company has a large acreage of coal land under lease in the southeastern Kansas field. A part of this the company itself is working, while much of it is being worked by smaller individual operators under sublease. The Midland company has a well-organized distribution system, and will operate as a distributing medium for the products of the Jackson-Walker mines, Mr. Clough said.

The merged companies have a capitalization of \$505,000, with a surplus of approximately \$600,000.

Mr. Clough obtained control of the Jackson-Walker company a few months ago by purchasing the stock holdings of the widows of the founders of the company.

Midwest Mines Get Little Running Time

Many Operations in Illinois and Indiana Closed for Several Months—Few Are Working More Than Two or Three Days a Week

The effect of low market on coal production in Illinois and Indiana can be seen plainly in the fact that about 70 mines in Illinois and 85 in Indiana are closed down and many have been down for several months. Few of those in operation have been able to get more than three days running time each week all summer and autumn. The average in both states is now a little less than 40 per cent of full running time for those mines that have avoided shutting down.

The 85 Indiana shutdowns were from a total of 204 mines that were in operation Jan. 1, 1923. These closed mines had a daily capacity of 62,561 tons. They constituted 41.6 per cent of the mines in operation in the state last January and the loss of their tonnage amounts to 33.2 per cent of the total capacity of all the mines—183,233 tons daily.

Sixteen of the Indiana mines were abandoned and scrapped because their territory was practically worked out, according to figures and reports filed with the Indiana Coal Trade Bureau, of which Jonas Waffle is manager. Of the 69 which have closed indefinitely, the reason in nearly every instance was, inability to operate at a profit.

It is said that the growing use of coke and the buying by large consumers of the products of the non-union mines of West Virginia and Kentucky are two main reasons for the falling off in demand for Indiana coal.

Another feature of the industry in Indiana is the discrimination in freight rates, Mr. Waffle pointed out. Operators from neighboring states at the present time can ship coal into Indiana at a lower freight cost than the Indiana operators can ship their coal within their own state. John Hessler, president of District No. 11, U. M. W. of A., says he believes this has had quite a good deal to do with the idleness of many of the mines.

Three Big Days with Coal Mine Institute

With the Question Box to the fore, as usual, the Coal Mining Institute of America will open its annual session at the Chamber of Commerce Auditorium, Pittsburgh, Pa., Dec. 19 and 20, and on Dec. 21 will close its session with a trip to the experimental mine at Bruceton, Pa., where the U. S. Bureau of Mines will stage an explosion and show the assembled members the rock-dust barriers, the explosives-testing apparatus and safety-lamp tests.

On Wednesday, Dec. 19, the morning will be devoted to reports of the Executive Board, an announcement of the elected officials, the election of tellers for 1924, an address by the president, Richard Maize, and one by Dr. George H. Ashley entitled "A Practical Classification for the World's Coals." In the afternoon a motion picture entitled the "Story of Dynamite" will be shown, Dr. R. R. Sayers will deliver an address on "Health Hazards in Coal Mining" and John T. Ryan one entitled "Some Observations on European Coal-Mining Conditions."

Three questions also will be discussed: "Does dynamite exert a greater force downward or does it exert the same force equally in all directions?" "What type of safety lamp is the more sensitive to gas—the flat or the round wick?" and "Is radio proving of any practical use in coal mining or for mine-rescue work?"

In the evening a dinner will be given at McCreery's Store with Richard Maize as toastmaster, and Dr. Daniel L. Marsh, pastor of the Methodist Episcopal Smithfield St. Church, "Old Brimstone Corner," as principal speaker. He is the author of "The Challenge of Pittsburgh." Captain Irving O'Hay, "The Soldier of Fortune" and a veteran of eight wars and also author of "From Dan to Beersheba," will come from New York City to address the banqueters, as also the Hon. Abe Potash, a coal operator of New Brunswick, N. J. The new president's address will complete the proceedings.

W. E. Fohl will lead Thursday morning's session, which will discuss three questions, the first being "what precau-

tions should be taken in installing an electrically driven exhaust fan at a gaseous mine to prevent the motor from igniting the gas in the return air when the ventilation is re-established, the fan having stopped long enough to allow the mine to fill with gas? Denver wants the answer. Cleveland, Ohio, will ask "What is the practical limit to the splitting of air currents?" and Altoona is pressing for a reply to the question "What changes in roof, bottom and coal are found when approaching a fault?"

Joseph J. Walsh, State Secretary of Mines, of Pennsylvania, will deliver an address on "Mine Fires and Some Methods for Extinguishing Them."

In the afternoon Thomas Chester will read his paper on "New Data Concerning the Humidification of Mine Air" and Nicholas Evans will preside over a discussion of four questions: "Where does the most dangerous dust lie—on floor, ribs or timbers?" "Is it possible to have an explosion in a mine where your safety lamp gives no indication of firedamp?" "What are the most common causes of the ignition of gas in coal mines?" and "How tight should posts be set in rooms and entries?"

Power and Mechanical Engineers' Exhibit

The power show to be held at the Grand Central Palace, New York City, Dec. 8, will have a complete showing of the latest devices used in measuring the flow of liquids and gases, as well as apparatus for the generation and utilization of power, including boilers, stokers, superheaters, economizers, transmission equipment, and various other items used in the power house.

The demand for increased economies in the operation of power equipment and power-generating equipment has accelerated the development of measuring devices, without which economy of operation is practically impossible. For these reasons the power-plant man interested in effecting savings will surely find much of interest in this exposition. Engineers coping with fuel problems will be interested in the exhibit of fuel burners such as stokers, pulverized-fuel and fuel-oil burners.

During the week of the exposition the annual meeting of the American Society of Mechanical Engineers will be held in the Engineering Societies Building Dec. 3-6, when topics of interest to fuel producers and consumers will be discussed.

Take Steps to Form Alabama Traffic Bureau

Alabama Mining Institute held its annual meeting at the Roebuck Country Club, Birmingham, Nov. 21 with a large attendance. Reports of officers were made on activities of the institute during the past year. The following new directors were elected to take the places of a similar number whose terms automatically expired with the close of the fiscal year: C. T. Fairbairn, manager of the Republic Iron & Steel Co.; J. B. McClary, president of the Yolande Coal & Coke Co., and S. L. Yerkes, president of the Burnwell Coal Mining Co. Officers for the ensuing year will be elected at a meeting of the directors, consisting of nine members, to be held in December. Steps were taken at the meeting toward the formation of a traffic bureau. The institute was addressed by Harry L. Gandy, secretary of the National Coal Association.

By a standing vote, Institute members announced a renewal of their confidence in the National Coal Association and authorized the appointment of a committee to make an effort for one hundred per cent local membership.

Mine Workers Silent on April 1 Program

Mum was the word among International officers of the United Mine Workers after the executive board meeting in Indianapolis, Ind., ending Nov. 20. Plans were made for the Jan. 22 annual convention of the union in Indianapolis, the call for which issues Dec. 1, but little was said about the probable program for the gathering and, of course, not a word about the probable platform of demands upon which the union expects to meet the operators before the end of the present wage contract, April 1.

Again Rejects Plan to Curb Hard-Coal Prices as Illegal

Warriner Tells Pinchot Proposed Agreement by Operators to Restrict Retailers Offends Criminal Statutes—Counsel Says Scheme Is Subterfuge

Governor Pinchot's proposal that the anthracite operators refuse to sell to retailers who charge more than the retail prices of 1922 "offends the criminal laws of the United States" and the plan cannot be accepted, according to opinion of counsel, S. D. Warriner, chairman of the anthracite operators' general policies committee, wrote the Pennsylvania executive No. 23.

Last week George W. Woodruff, Attorney General of Pennsylvania, rendered an opinion that the operators could agree with one another to control prices for the benefit of the public without infringing on the common law, "although they might be in danger of prosecution under the Sherman law if they agreed to hold prices below a maximum. It is hard to find how they could be attacked unless the federal Department of Justice were hostile to action in favor of the public interest," said the opinion.

WARRINER PRESENTS OPINION OF COUNSEL

Mr. Warriner enclosed an opinion by Walter Gordon Merritt, of New York, which said Governor Pinchot's proposal "involves the commission of criminal acts either directly or by subterfuge and should be declined."

In his letter Mr. Warriner said:

"The enclosed opinion of counsel can leave no reasonable doubt that the only proposal made by you to the anthracite operators, at our recent conferences, offends the criminal laws of the United States. From this follows other conclusions involving the hostile attitude which you have seen fit to take against one of the great industries of our state.

"You assumed to furnish a solution and stated to us that your proposals must be accepted or you would attack the industry. You are now carrying out that threatened attack because of our inability to accept a plan which is both impracticable and unlawful.

"A policy of fixed antagonism on the part of state officials obstructs, rather than promotes, our efforts to meet the problems of the industry and the reasonable expectations of the public.

"Permit me again to express our desire to fully co-operate with the State of Pennsylvania in any lawful and practicable plan."

Mr. Merritt's opinion said in part:

"The Attorney General holds that such a scheme would constitute a crime under the Sherman Anti-Trust law, and with this view I am in entire accord. To evade the application of the Sherman Anti-Trust law, the Governor now urges that the same end, though illegal when accomplished by direct agreement between the operators, can be legally accomplished by independent but uniform agreements between each operator and the Governor.

"The Supreme Court of the United States denounced all such evasions. It ruled in the tobacco case that the Sherman Anti-Trust law "embraced every conceivable act which could possibly come within the spirit or purpose of the prohibitions of the law, without regard to the garb in which such acts were clothed. . . . In view of the general language of the statute and the public policy which it manifested, there was no possibility of frustrating that policy by resorting to any disguise or subterfuge of form, since resort to reason rendered it impossible to escape by any indirection the prohibitions of the statute.

"The Governor cannot legalize such a scheme. The Supreme Court held that President Roosevelt's approval of the acquisition of certain property by the Steel Corporation did not make it legal. The suggestion of the Attorney General that such a benign combination, though illegal, would be free from attack 'unless the federal Department of Justice were hostile to action in favor of the public interest,' ignores the fact that boycotted dealers would demand that

federal authorities perform their sworn duty to enforce the law. The operators cannot afford to place themselves in jeopardy by violating the federal statutes and relying upon the connivance of the federal government for protection."

Illinois Mining Institute Is Told People Should Appreciate Cheapness of Coal

John L. Lewis, International president of the United Mine Workers of America, was principal speaker at a luncheon held by the Illinois Mining Institute at the American Annex Hotel in St. Louis, Mo., Nov. 24. This was one of the largest meetings ever held by the institute, about 250 persons being in attendance.

Mr. Lewis in discussing the differences in living, working and operating conditions between the United States and Great Britain, declared that Americans too often failed to realize that coal was produced and sold for less here than anywhere else in the world, that the British miner produced one ton per day as compared to the four tons which the American mine worker regarded as a proper day's work. The British miner was slow, but the operator did not show any greater speed, his buildings and equipment with a few exceptions not being up to date.

He urged that the evils in the coal industry could best be solved by those who were in it. He declared that Congress could not find a solution and any it might think it found would not remedy the situation and probably would be unconstitutional. He had faith that the operators and mine workers would work out their difficulties in conference.

Herman C. Perry, vice-president of the Fifth and Ninth Districts Coal Operators' Association, the second speaker at the luncheon, said that neither the operator nor the mine worker could be blamed for the excessive development of the coal industry in Illinois. It was caused by the apprehension of a fuel shortage arising from the inability of the carriers to fulfill their duties. Only once, said he, in forty years had there been an actual coal shortage. If the railroads had been able to handle the tonnage when the peak demand came there would never have been any overdevelopment.

Mr. Perry spoke with much favor regarding a bill offered in the last session of the Illinois Legislature which would, in his opinion, have been the biggest step made in recent years in the coal industry. It provided for the retreating system of mining. The bill failed. Had it passed it would have eliminated the small mine and would have given us large mines but fewer of them, thus decreasing the cost of distributing, collecting and hauling railroad coal cars. The mines now in operation in Illinois were, he added, capable of supplying the demands made on the Illinois fields for the next twenty-five years without the opening of another mine. If there were coal equipment available Illinois could produce a million tons a day.

At the technical session, J. A. Ede, consulting mining engineer, of La Salle, Ill., discussed new methods in longwall, arousing some disagreement but on the whole finding a general approval of his advanced opinions. Harvey E. Smith, general superintendent, Leland Coal Co., Springfield, Ill., discussed coal mining in South America.

At the business session, which concluded the meeting, the following were elected: D. D. Wilcox, superintendent Superior Coal Co., Gillespie, Ill., president; Harvey E. Smith, first vice-president; E. G. Lewis, superintendent, Chicago & Sandoval Coal Co., Sandoval, Ill., second vice-president; Martin Bolt, secretary and treasurer (eleventh time); George K. Larrimore, Springfield, Ill.; F. F. Tirre, St. Louis, Mo.; J. A. Jeffries, St. Louis, Mo.; Sam T. Jenkins, St. Louis, Mo., and Bruno Meyers, Staunton, Ill., directors.

ANNOUNCEMENT WAS MADE in Washington last Saturday that the U. S. Attorney for the District of Columbia will ask an indictment of certain Washington retailers on the ground that they have entered into an understanding as to prices. Previous efforts to prove violation of the law by District of Columbia retailers have failed.

Draft Bill for Compulsory Cost Returns to Trade Commission

Blunder Seen in Operators' Failure to Report Voluntarily—C. P. White May Be New Coal Chief of Commerce Department

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Friends in Congress of the Federal Trade Commission are prepared to insist that there be no repudiation of the commission in the matter of gathering figures on the cost of producing coal. There are a number of national legislators who are expected to insist upon compulsory returns being made to the Federal Trade Commission. Whether the figures are to be submitted voluntarily or on a compulsory basis, the friends of the commission feel that they should go to this agency of the federal government since it was the commission that first embarked on this activity and would be continuing it were it not for the legal technicalities which have been placed in its path by those from whom the returns must come. To allow this function to pass into the hands of the Department of Commerce or any other government agency, in their opinion, would be a sort of repudiation of the commission, or at least it would be failure to uphold its hands.

There are other members of Congress who fear the coal industry would be dealt with too sympathetically were cost figures to be gathered by the Commerce Department. Their idea is that the Federal Trade Commission would come nearer getting the real facts. The experience with the railroads has taught many members of Congress that it is one thing to obtain returns, but quite another to procure figures that tell the real story. There are many who believe most railroads are earning, in effect, more than is indicated by the bare returns to the Interstate Commerce Commission. If either voluntary or compulsory figures are submitted to the Federal Trade Commission, there is a feeling among some members of the national legislature that they would be interpreted not so much as the industry would like but in a way best calculated to serve the public interest.

It is known definitely that a bill has been drafted providing for compulsory returns of cost data to the Federal Trade Commission.

As the situation is shaping itself, the seriousness of the mistake of the operators in not starting the voluntary returns which they promised the Coal Commission is becoming more apparent. Had this plan been put in operation immediately after it was suggested, it is improbable that Congress would have disturbed the arrangement. Since considerable time must elapse from the time legislation is introduced until it is brought up for final consideration, there still is time for the industry if it prefers to co-operate with the Department of Commerce rather than the Federal Trade Commission, to get the plan under headway.

N. C. A. BLAMED FOR CLOUDING SITUATION

The National Coal Association cannot be blamed too severely because of the uncertainty injected into the situation by the fact that Mr. Wadleigh was to leave the department. To reach a thorough understanding of such a plan, many conferences are necessary and much effort must be expended. The operators took the view that it would be better to await the advent of Mr. Wadleigh's successor before attempting to launch their proposal.

As this is written, it seems probable that the new chief of the Commerce Department's Coal Division will be C. P. White. It is known definitely that Mr. White may have the position if he will accept. Mr. White's decision in the matter is expected within the next few days. It is generally admitted that Mr. White is excellently qualified to fill this position. It is well known that he enjoys the confidence of the industry and it is believed that the members of Congress interested in coal will agree that he can be relied upon to be entirely conscientious in the discharge of his duty to the public.

The hope is expressed by persons outside of the coal

industry, who are anxious to see that industry spared the burdens of regulation, that the voluntary returns to the Department of Commerce can be begun prior to the introduction of the bill which would divert the figures to the Federal Trade Commission. If the arrangement starts functioning after that date, there would be ground for the belief that it was contemplated seriously only when the Federal Trade Commission idea was proposed. The chance of preventing the designation of the Federal Trade Commission as the agency to receive coal-cost figures has been reduced by failure to get the plan under way, but it is apparent that even a late start with the Department of Commerce would put the operators in a better position to carry out their desires than would be the case if no start at all were made.

Madeira, Hill & Co. Deny Agreement To Enhance Anthracite Prices

Madeira, Hill & Co., of Philadelphia, anthracite producers, have made a sweeping denial of the charge made by the Federal Trade Commission that the company entered into a secret agreement with certain wholesalers to enhance the price of anthracite beyond that recommended by the Fair Practices Committee of Pennsylvania during the recent strike. Madeira, Hill & Co. was one of six defendants named in a complaint by the commission, the others being wholesalers.

While admitting the Fair Practices Committee had recommended that \$10.50 per ton at the mines for prepared sizes of anthracite would be a fair price, Madeira, Hill & Co. denied it gave any assurance to the committee that it would observe such a price and also denied that it was under any obligation to observe such price.

The total amount of tonnage involved in the sales to the defendant wholesalers amounted to 2,783 tons, it was stated. "Such sales were so trifling in comparison with the total anthracite production that they could not possibly have enhanced or affected the price of coal to the consuming public," the firm's denial said.

Denying the commission has any jurisdiction over the matter of billing any sales made by it, Madeira, Hill & Co. informed the commission "that for some months, prior to the filing of the complaint, all of its sales had been billed, and now are being billed, at the prices at which the coal is sold."

The case will be heard by the Commission on Dec. 3.

The Federal Trade Commission has overstepped its powers in attempting to determine "what is an unfair, unreasonable and unjust margin of profit on anthracite," according to answers filed with the commission Nov. 15 by two of the wholesale coal dealers named in complaints filed by the commission for pyramiding of prices.

If business men generally adhered to the margin of profits determined by the commission they would be driven "into insolvency and trade stagnation," coal dealers declared. The answers were filed by C. P. Brodhead and Lynn M. Ranger, located at Boston; the Titan Fuel Corporation and Pattison & Bowns, Inc., New York City.

The latter company, after admitting the functions of the office of the Federal Fuel Distributor during the national coal emergency, denied any knowledge or information of how many states "by legislative enactment or proclamation co-operated with the federal government in coping with the emergency."

The first-named respondent declared that its information in regard to the appointment of a "Fair Practices Committee by Governor Pinchot of Pennsylvania and a commission appointed by the Federal Fuel Distributor" was received in the newspapers, "but at no time did it receive any communication from these committees to work in conjunction with the Federal Fuel Distributor."

This respondent also questioned the authority of the Fair Practices Committee of Pennsylvania, but after an investigation ascertained it was a voluntary committee, with no authority under the law.

Pattison & Bowns characterized as absurd the charge that they had entered into a conspiracy with Madeira, Hill & Co. to enhance prices.

Production and the Market

Weekly Review

The soft-coal market lacks the usual November snap. Buying of free coals is being done very quietly and cooler weather is needed to bolster up the trade. Current needs are taken care of only when the lowest prices prevail. With the Lake season drawing to a close the mines shipping coal to Lake Erie ports are affected and more closings are reported. This situation has been reflected in the volume of screenings available for spot buyers in the West and has resulted in a stiffening of prices. Smokeless lump suffered a reduction of prices in practically all Western markets, while the steam-coal market showed more strength. The tidewater markets have been strengthened by a practically cleaning up of distress coal.

However, soft coal prices advanced last week to the level attained on Oct. 22, *Coal Age* Index showing 186, an increase of three points from the previous week. The average price was \$2.25. For the corresponding week of 1922 the Index registered 330 with an average price of \$3.99. Increases were recorded in Springfield, Indiana, eastern and western Kentucky, Hocking, Pocahontas, Pittsburgh, Clearfield and Kanawha coals.

INQUIRIES MORE NUMEROUS; ORDERS SCARCE

Operators and shippers see a ray of hope in the increased number of inquiries, but new orders are scarce.

Although many mines are closed, production of soft coal during the week ended Nov. 17 is estimated by the Geological Survey to have been 9,684,000 net tons, a decrease of 1,042,000 tons from the previous week, reports indicating that Armistice Day counted only a little more than one-half a normal Monday. Indications point to a production in the neighborhood of 10,500,000 net tons for last week.

There was a marked depression in smokeless coals in the Middle West, but a strengthening in steam coals. Taken altogether the situation is not favorable. Business is practically at a standstill in St. Louis. Similar conditions regarding smokeless coals exist in the Cin-

cinnati market. There is a surplus of tonnage available, although many of the mines in southeastern Kentucky are closed. There is little demand and strength in the Columbus market, while at Cleveland business is dull. Production in the Pittsburgh district is being curtailed in keeping with the decrease in Lake shipments, which also has resulted in a slight betterment in slack. There is no improvement reported from New England, but it is noted that distress coal has been cleaned up. A slight encouragement is apparent in the textile field.

Production of anthracite was 1,725,000 net tons in the week of Nov. 17, according to the Geological Sur-

	Week Ended Nov. 19	Season to Nov. 19
Cargo	890,874	28,290,920
Fuel	43,554	1,522,572
Totals	934,428	29,813,492

vey, a decline of 242,000 tons when compared with the previous week, the decrease resulting from Armistice Day idleness. It is estimated that output exceeded 2,000,000 tons last week. Demand for high-priced coals is rapidly disappearing and most shippers believe that it will practically be out of the market before the end of December. Demand centers around stove and

chestnut coals, with egg and pea sizes much more in evidence. Steam sizes move slowly.

The export situation looks brighter. Reports from Great Britain indicate that the effect of American competition in the Mediterranean is being felt. Dumpings at Hampton Roads for all accounts during the week ended Nov. 22 amounted to 264,302 net tons, as compared with 290,492 tons in the previous week.

Midwest Steam Coal Firmer

A slight strengthening of steam coals and further depression of Eastern smokeless on the Chicago market were the only notable features of Midwest coal trading during the week. Production has been low for so long that the supply of screenings is small enough to cause a trifling improvement, and this was sufficient to firm up the bottom of the steam market.

Production throughout Illinois and Indiana continues at less than 40 per cent and the market generally is lifeless. There is still a place to put almost all the domestic lump, but no keen demand for it. The recent drop in the prices

of egg and nut sizes in order to relieve the load of "no bills" has had only a little effect. The tremendous production of smokeless in the East has finally mashed down the price of smokeless lump still further. Lump that sold for \$6.25 a few weeks ago is now dragging along on the Chicago market at a bare \$4.50. Smokeless mine-run is hardly able to stay above \$2. The situation generally throughout the Middle West is not cheerful, but cold weather is closer.

St. Louis Trade Is Flat

Warm weather continues in the St. Louis territory and business is at a standstill. The situation is the same in the country as in the city and dealers have their yards full of coal and their equipment idle. Local wagonload steam is quiet. There is no activity in carload steam, either local or in the country, excepting a little moving toward Chicago at prices below cost.

Never in the history of St. Louis have conditions at this particular season of the year been as bad as they now are. In spite of the failure to move coal the low level seems to have been reached. Conditions that are gradually growing worse fail to change prices.

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

	1923			1922
	Nov. 26	Nov. 19	Nov. 12	Nov. 27
Index	186	183	184	330
Weighted average price	\$2.25	\$2.21	\$2.23	\$3.99

This diagram shows the relative, not the actual, prices on four-teen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

Southern Illinois mines continue to shut down on account of no market and the entire field has taken on an air of depression that will disappear only after a lot of cold weather arrives. Cars are plentiful and the movement of loads is good, but all mines have plenty of "no bills." There is considerable dissatisfaction at different points among the miners. This condition prevails in every field—Carterville, DuQuoin, Mt. Olive and Standard. Railroad tonnage in all fields is light and not much encouragement is held out for any change for the better until cold weather arrives.

Kentucky Market Dull

In spite of low prices in the western Kentucky field some concerns have been quoting prices at considerably under the market on nut, egg and small lump sizes. Coal is hard to sell at any price just now. Retailers are fairly well stocked. Steam coal is moving sluggishly to industrials and railroads. Many large consumers are well stocked, and buy only on the market dips or when coal is offered at well under the usual market.

Screenings are selling for 60@75c., and while some houses are quoting as high as \$1.25@\$1.35 for 3-in. nut and slack, so-called nut and slack is selling as low as 75@85c. a ton, as a lot of operators cannot find a nut market, and do not figure that it pays to screen it when a ready market

is not available. Mine run is \$1.50@\$2, good nut \$1.75@\$2.25; egg, \$2.25@\$2.75; and lump \$2.50@\$2.75, while block is quoted at \$2.75@\$3.25. However, there is a good deal of shading being done from these prices.

In eastern Kentucky some non-union mines that are working on the 1917 wage scale and low-cost strippers continue to disturb the market by underselling most producers. Retailers are waiting as usual for a lower market, and may profit by so doing, as prices are working lower on prepared, but at the same time there has been no improvement on screenings.

Northwest Market Still Dull

Little life is noted yet in coal trading throughout the Northwest. Unseasonably warm weather and the long-price cutting battle between lake and rail shippers still combine to produce lethargy. The soft-coal market is about as demoralized as it could be. In most parts screenings continue to sag in price. Other quotations remain steady on circulars but cutting to get business prevails on occasion. The region feels better about hard-coal supplies though popular sizes are still a little short.

Trade at Duluth remains lethargic, with heavy shipments of bituminous coming in and crowding the docks, slight stocks of anthracite on hand, and buyers watching generally for some shifting in the soft-coal market. Hocking screenings have dropped from \$3.75 to \$3.50 and shading is taking place in Youghioghenny and splint coal of the same grade. Other grades are firm at Duluth.

The anthracite situation looks as if it were ready for improvement. In forty-eight cargoes landed last week four were hard coal, and of the twenty-four reported on the way, five are hard. All docks are short of nut size, and stove is not plentiful. Prices remain firm in anthracite with no sign of increasing.

It is estimated that the largest shipments of soft coal will be recorded at Duluth this year for several years past. The total arrivals of soft will come to almost 11,000,000 tons.

The Milwaukee market is quiet. Winter has not yet arrived, consequently the demand is light. The same is true of the back country. Jobbers report everybody well supplied with coal and disinclined to contract for more. Prices hold steady. Lake receipts continue liberal and stocks on hand are increasing daily. November's record thus far is 91,500 tons of anthracite, and 454,361 tons of soft coal, making the season's cargo receipts to date 875,824 tons of the former, and 3,052,062 tons of the latter.

Western Markets Lifeless Too

Coal business generally is low throughout the West with no outstanding improvement anywhere. Running time in the Southwest as well as in Colorado and Utah is low with the trade bemoaning the absence of enough demand to keep mines entirely clear of "no bills." Lump moves with some ease, but slack drags and middle sizes must be forced. Hence there are all sorts of quotations on egg and nut sizes. Circular on those coals mean little.

In Utah lump orders are about all filled and slack is heavy on producers' hands so that the general market comment of sales officials is "Trade is rotten." All sorts of prices on egg and nut sizes are out, varying up to \$1 from day to day, but lump holds fairly firm. A good deal of coal has been shipped on consignment into the Northwestern states and causes the usual demurrage difficulties. It is generally held that the supply of coal in consumers' hands is not large and that a real cold snap will bring a rush of demand.

More Coal Available in Ohio

With the lake trade practically over for the 1923 season more coal is available in the Ohio territory, although production is being reduced because of the lack of demand. Quotations on smokeless lump coal took a sudden drop in the Cincinnati market during the week and large producers were selling as low as \$4.50, although some have refused to cut below the cost of production on mine-run and the higher grades. Retail prices remain stationary.

Buying continues quiet in the Columbus market and is expected to continue so until stimulated by cooler weather. Retail dealers are well stocked and it is said in some instances are cutting prices in order to move their supplies. With large reserves in storage, buying of steam coal is slow, with distress coals showing the only activity. Screenings, which started to show some strength, are easier because of the absence of some of the heavy buyers from the market.

Operators and jobbers in the Cleveland market say it has been a long time since conditions have been so dull. There is no demand for any size of coal. Consumers of all kinds are well stocked. Reports that more mines will close are current, as production is exceeding demand.

There is still a fair movement of lake coal from the Pittsburgh district, although these shipments have been tapering off. Production is being curtailed in order to meet the lowering demand, but it is lessening the volume of slack available. The result has been an advance in quotations for this grade of coal. Cement makers, who use slack exclusively, either steam or gas, bought heavily in anticipation of present conditions at the old market quotations of 85c. to \$1 and are pretty well stocked up. There is no noticeable increase in the line demand for either steam or gas coal.

During the week ended Nov. 17 car loadings in central Pennsylvania amounted to 12,900 cars, as compared with 14,177 cars the week previous and with 11,779 cars during the week ended Nov. 3. The decrease in loadings is taken by the operators to indicate increased competition with non-union coal.

New England Shows Little Change

In New England there is little change in the market for steam coal. No improvement in inquiry is yet noticed, although the gradual absorption of distress coal both at Hampton Roads and "down East" has given factors there an opening to quote higher prices to the smaller buyers. Ostensibly the on-car level at Boston has been lifted to \$5.75 @ \$6 for No. 1 Navy Standard Pocahontas and New River, but at the same time there has been quiet selling at 50@75c. less in moderate quantities to make room for cargoes in transit. A very few consumers are making small purchases as weak spots appear, partly on general principles and also to insure against increased requirements between now and spring. Some of the agencies show enough willingness to undertake contracts for January to March periods to discount talk of possible labor troubles later on. In general the spot market is but little improved as compared with a week ago.

F.o.b. Hampton Roads there are also higher quotations than were shown in our previous report; \$4.50@4.80, however, is about the range of actual sales in cargo lots. Demand is no better, but there is less coal on wheels than earlier in the month, and curtailment in the smokeless districts is now the rule.

There is practically no new business in New England for all-rail coal from central Pennsylvania. The high tariff to points east of the Connecticut River precludes competition with Southern coals on the present basis and apparently there is nothing to do but await better things. No better price level is noted on any of the coals normally shipped in this direction all-rail.

Better Inquiry on Seaboard

Inquiry for soft coal increased slightly last week in the New York market, but buying failed to show any improvement. With distress coal practically out of the way quotations for the various grades at the piers were somewhat stronger. Receipts were slower, 1,218 cars being reported at the various piers on Nov. 23, while daily dumpings during the first five days of the week averaged 395 cars. There is a better feeling, but increased buying is not expected until the new year. The spot market at Philadelphia continues to hover around the better grades of coal and the consumer finds it difficult to get a supply below the general market quotations. Some consumers are beginning to talk of April 1. The tidewater trade is unsatisfactory, with little coal moving that way.

Demand at Baltimore for both gas and steam coals for home consumption is below the average. Buying is being urged by the producers and low quotations are the rule. Some coal men look for an upturn in December while others do not look for so early an improvement.

In some sections of West Virginia there has been a slight improvement in slack due to the curtailment of shipments to the Lakes, quotations hovering around \$1. Improvement is noticed also in the higher grades of smokeless coals, due to more favorable conditions at tidewater and no accumulations. More mines are closing, but this has not affected production to any great extent.

The Birmingham market is in an unsatisfactory condition, with practically no demand for spot coals. The domestic market is suffering from unseasonable weather conditions and only the best qualities of the suitable coals are moving. Some improvement is reported in the pig iron market, with the prospect of additional furnaces being blown in soon, which will tend to increase coal production by the furnace company mines, many of which are now either idle or working on about half schedule.

Anthracite Market Active

Lack of stove and chestnut creates the real activity in the anthracite market. These two sizes are in constant demand in the seaboard trade, while egg and pea are becoming harder to move. While some houses in the New York market continue to quote as high as \$12.50 for the domestic coals, few if any sales at this figure are reported. Retail dealers in the territory served by local houses are buying comparatively little of the high-priced coals, and in most instances are able to buy at much lower figures if they can use a proportionate share of the steam sizes. In Philadelphia similar conditions exist. Demand is centered on stove and chestnut and there are signs that this situation is righting itself. Indications are that in a few weeks there will be plenty of all sizes of anthracite available to fill all demands.

More seasonable weather conditions are helping the steam-coal situation and there is a slightly better movement, although storing is still necessary to take care of accumulations.

Baltimore dealers continue to complain of lack of receipts sufficient to take care of their customers' wants. There is no emergency, however.

Production of beehive coke during the week ended Nov. 17 was 246,000 net tons, a decrease of 9,000 tons from the previous week, 8,000 tons of which decline is attributed to Pennsylvania and Ohio, according to the Geological Survey.

Foreign Market And Export News

Great Britain's Coal Market Shows Firmer Tone; Production Slightly Reduced

Reduced production of coal by Great Britain's mines has resulted in a firmer tone to the market and a slight advance in prices. Output during the week ended Nov. 10 was 5,572,000 tons or 23,000 tons less than the previous week. Production during the corresponding week of 1922 was 5,440,500 tons.

The somewhat steadier tone of the Welsh market has been considerably upset by the severe gales which delayed shipping and resulted in empty berths.

France is buying on a better basis, orders are more free from Germany, and business is better with Holland and Belgium. The Italian trade is slow.

Considerable interest is shown in contract sales for 1924. Approximately 200,000 tons of coal and coke are reported sold to Germany for delivery over the next six months. One effect of the shortage of ready steamers is that freights have a stiffening tendency, and exporters delay chartering as long as possible in the hope that there will be a fall in the current market.

The Newcastle market is strong but is hampered by delays to shipping through gales. Best steam is oversold and there will be none available till January. Germany is inquiring for steams for the State Railways. The pressure of American competition in the Mediterranean is being felt. There is not much contract business.

French Miners' Wages Increased

Agreements have been made between French mine owners and miners whereby the workers in the North and Pas-de-Calais Basins receive increases in wages during the period from Nov. 1 to the end of February. The new schedules provide that under-ground men shall receive increases ranging from 2.75 to 3 fr.; younger crews, 1.25 to 1.75 fr.; surface men, 2.50 fr.; younger classes 1 to 1.75 fr. and women 1 to 1.25 fr. In the Loire Basin the new agreement provides for increases ranging from 2.50 to 1 fr. according to the character of work. In the other basins agreements have been arrived at or are

being discussed. Although the new agreements provides for wage increases it is said they are not satisfactory to all workers. Advances in the prices of coals is now looked for.

Inquiry for industrial and house coals is not active. Buying is slow and retail yards contain a large supply of house fuel. Paris dealers are now prepared to meet the Government's requirements for "popular" coals which will sell around 200 fr. per ton, and if sufficient Ruhr lignite briquets can be obtained they will be disposed of at 170 fr. In addition the Nord and Pas-de-Calais collieries will send to the Paris Prefecture a monthly supply of about 5,000 tons of special coals, to be distributed at a very low cost among the poor.

France and Luxemburg received during October the following tonnages of indemnity fuels: 144,200 tons of coal; 195,600 tons of coke and 14,700 tons of lignite briquets. Coke receipts by the S. C. O. F. during October were 132,175 tons. An advance of 8 fr. per ton is expected in the price of manufactured coke as a result of the increase in wages, and as a similar increase is to be made on German coke according to the agreement with the French Government, it is expected that the latter will be quoted at 134 fr. per ton.

Market at Hampton Roads Weak

Business at Hampton Roads was not particularly active last week, the strike on the Virginian Ry. resulting in marked decrease in coal movement, while the Chesapeake & Ohio piers at Newport News showed a decided slump. The Norfolk & Western alone held its own.

Export business dropped to practically nothing, with little new foreign business in sight. Coastwise trade was fair and bunker business was good, the former showing a tendency to increase with the approach of cold weather.

The market weakened in spite of the scarcity of coal at the piers, all grades being quoted far below \$5 which for many months was regarded as the low-

est possible market. Despite curtailed movements over the Virginian Ry. no shortage of coal was anticipated, the demand being much less than supply.

News Items From Field and Trade

ALASKA

The government-owned coal mine at Chicaloon, which has been producing a little naval coal of good grade, has been closed down under orders from Washington, the pumps and machinery have been pulled out of it and the mine is now flooded. The Eska government mine, however, is held in readiness to produce coal on short notice.

J. J. Corey, for several years a mining engineer at Coos Bay, Oregon, on the Southern Pacific Ry., has been made assistant to B. D. Stewart, supervising mining engineer for the Bureau of Mines at Juneau.

ILLINOIS

Governor Small has appointed Martin Bolt of Springfield as director of the Department of Mines and Minerals. He will take charge Dec. 1, succeeding Robert M. Medill, who has resigned. Bolt has been assistant director of the department. A. D. Lewis, of Springfield, a brother of John L. Lewis, international president of the U. M. W. of A., becomes assistant director.

Attempts of creditors to force the Smith Lohr Coal Mining Co., of Pana, into bankruptcy have failed. The creditors charged that the company transferred its holdings to the Springside Coal Co. to avert payment of claims held by them. Attorneys for the Smith Lohr company state that the Springside company is a corporation formed to lease for a year property of the Smith Lohr company, a receiver for which had been appointed in the Christian County Circuit Court. This lease they said was approved by the Christian County court and was made in order to keep the Smith Lohr company afloat and not to avoid payment of any claims. The creditors' bankruptcy petition has been denied.

The Clarke Coal & Fuel Co. of Peoria, has discontinued business. For a score of years this company has employed about four hundred miners and its average weekly payroll has been about \$60,000. These miners are now seeking employment at other mines. The mines and all equipment have been purchased by the Case and Moon coal companies, of Peoria, and these operators will handle the Clarke property in the future.

The Coal Valley Mining Co., Mathersville, has dismantled its buildings and shipped its machinery to other mines owned by the company. The old shaft has been fenced in and only an ash pile remains to recall the industry which was established 14 years ago. At one time this mine employed about 200 men. The mine has been idle for the last two years.

Although many mines have now closed down entirely or are working only part time, the nine months of 1923 between Jan. 1 and Oct. 1 were record breaking months in the production of coal in Central Illinois. A total of 3,500,000 tons more of coal have been mined in the first nine months of 1923 than were produced during the corresponding period of 1922. From January 1 to Oct. 3 a total of 10,551,569 tons were mined.

No. 4 car of the U. S. Bureau of Mines was stationed at the University of Illinois,

STANDING AT EXTREME LEFT, R. S. CORBIN; NEXT TO RIGHT END, W. W. HUNTER

Urbana, two weeks this year, during which time the seniors in mining engineering were given short but intense courses in first-aid and mine-rescue work. A. J. Hoskin, acting head of the department, hopes to have the courses repeated annually, as the students showed deep interest in the work. They received their certificates from the Bureau and also have taken examinations and passed in competency under the Illinois regulations.

William Hutton, of Du Quoin, who for several years has held various positions with the Illinois Mine Workers union, has resigned and will hereafter be connected with the Illinois Coal Operators Association as a field man with headquarters in Springfield.

During the month of October and in spite of the poor marketing conditions, the Southern Gem Coal Corporation broke its total hoisting record at mines Nos. 1, 5 and 6. The latter two mines are in Perry County while the former is located near West Frankfort, in Franklin County.

A. J. Hoskin, acting head of the mining engineering department, University of Illinois, Urbana, was recently in the Jellico field of eastern Tennessee inspecting mines in the Swamp Angel, Blue Gem and Jellico seams.

INDIANA

The United States Steel Corporation has made arrangements at Universal, where it owns two coal mines, to install fire protection for the mining town. A complete fire department will be installed, pipes being laid throughout the village, hose purchased, apparatus furnished and placed in a building especially built to house the department.

Fire caused a loss of \$25,000 or more in the tippie building and hoisting apparatus at the Interurban Coal Co. property, known as the Struggling Monkey mine, northeast of Clinton Monday, Nov. 19. About 150 men will be thrown out of employment. The mine was formerly operated by C. W. Whitlock, of Terre Haute. The origin of the fire was not determined.

Drilling for coal has been begun at Weldon by L. M. Butts and L. G. Jamison, on land belonging to the former. Indications are that coal will be found at a depth of 200 to 250 feet.

The Pershing mines near Knoxville, have been busy recently. The tonnage for two weeks in October averaged 1,650 tons per day from No. 12 mine. Officials state that this has been the best year, with the largest output of coal, since the mine began operating. During 1923, up to October, the Pershing mines produced 260,000 tons of coal.

KENTUCKY

It was reported from Harlan on Nov. 8 that the plant of the Wisconsin Steel Co., at Benham, near Lynch, had closed down its No. 2 mine, throwing 400 men out of work. It was reported that the company has good stocks of coal in its steel-mill yards and had found that it could buy coal cheaper than it could produce, and from the Central Competitive Field, with a shorter freight haul and lower rate. It was also reported that the Wilson-Berger No. 2 mine had closed, and that the Harlan Collieries Co., at Ages, was planning to close soon.

The Barking Coal Co., of Kimball, W. Va., is making preparations to develop new coal lands located near Dalna, Letcher County. The company operates the Barking mine at this place, on the L. & N. Ry.

The Porter-Givan Co., which was recently incorporated in Aberdeen, has organized with C. H. Givan, of Spring Lake, president and manager, C. V. Porter, secretary and treasurer. Coal lands are under development. Daily output is about 225 tons.

The homes of two non-union miners employed by the Hart Coal Corporation, a company which has been running "open

shop" since July 1, were fired upon, and bundles of switches along with threatening notes were left on the doorsills early in November. The county attorney's office has been investigating the cases. There has been no follow-up to the threats.

MARYLAND

Announcement has been made that the strike in progress for the last eighteen months in District 16, embracing the Upper Potomac field and the Georges Creek region, has been called off by the International organization of the United Mine Workers. Operators in these fields declined to become parties to the agreement which terminated the last nation-wide strike and announced that they would operate their mines open-shop. Although a few of the smaller companies signed an agreement most of the mine owners refused to do so and have been successful in mining coal without an agreement with the union. A number of the miners originally on strike returned to work. Calling off of the strike is construed to mean that such miners in the district as have refused to work will no longer be aided by the union and that the union organization will have to be abandoned. If that is the case it means that two districts have been wiped out as a result of the 1922 strike—districts 16 and 29—the latter having embraced the New River field.

MASSACHUSETTS

Representative Treadway of Massachusetts has sent an open letter to Governor Pinchot of Pennsylvania calling on the Governor to answer five questions relating to the coal situation. They are: "Will you call a special session and recommend the repeal of the state tax in order to reduce the cost of anthracite to the consuming public by about \$8,000,000? Will you allow this tax to continue in effect until the regular session of the legislature in 1925? Will you use your great influence to reduce the royalties now extortionately laid on the consuming public by the land owners in your state? Will you set these examples to the operators and then repeat your request to them to refuse their profits? Will you arise to the opportunity or will you continue to act the part of a demagogue?"

Attorney General Daugherty in a letter to Congressman John Jacob Rogers says that proper legal action is being prepared by the Federal Department of Justice regarding certain features of the anthracite industry and will be taken very soon. Mr. Daugherty's letter was in reply to one from Mr. Rogers asking that the department make a searching inquiry to determine whether there was a conspiracy in the Pennsylvania coal fields to muzzle the public by price manipulations. Congressman Rogers said that he does not think much congressional legislation regarding anthracite was necessary, as there was "law enough now on the statute books to pull down the price of anthracite to the consumer."

MINNESOTA

Civic bodies of St. Paul and Minneapolis have filed statements in Washington, protesting against the proposed 11c. decrease recommended on coal freights from the docks to the Twin Cities. This would cut the rate for soft coal from \$1.82 to \$1.71. They contend that any rate in excess of \$1.50 is discriminatory against the Twin Cities, and state that if a permissive order were issued by the commission, the roads would voluntarily put that rate into effect.

NEW YORK

The Walter Engineering Corporation, of 299 Broadway, announces the affiliation of David L. Wing as an associate. Mr. Wing is an expert economist and accountant. He has just completed work for the U. S. Coal Commission and comes to the firm with an exceptionally thorough grasp of the economics and facts of the coal industry.

The Pennsylvania Fuel Co., with \$20,000 capital stock, has been organized at Buffalo, with Clayton Ewell, president and George J. Mechau, vice-president.

Sealed Proposals will be opened by the Superintendent of Lighthouses, Staten Island, 2 p.m., Dec. 3, 1923, for approximately 1,800 tons bituminous steam coal during January, February, and March, 1924, in quantities as required trimmed in vessels bunkers under contractor's coal chute, New York Harbor. Information on application.

Governor Smith at the request of the mayors of the respective cities, has appointed the following fair-price coal commissioners to act with two commissioners appointed by the mayors, one to represent the consumers and the other the dealers: For Corning, Aaron F. Williams; for Yonkers, Dr. Elmer A. Sheets. With the exception of Schenectady, no other cities have made requests for the appointment of such commissioners. As soon as Mayor Whitmyre of Schenectady names the two commissioners for that city, Governor Smith will name a commissioner to represent the state and act with them. Some of the cities from which the governor has heard have said they have no need for such a commission.

The Fair Price Coal Commission of New York City on Nov. 20 announced its schedule of what it regards as **fair prices for anthracite** in the five Boroughs as follows: Manhattan, \$14.25 a ton; Brooklyn, \$14.50 to \$15 dependent on the distance from tide water; The Bronx, \$14.25 to \$15; in Queens, \$14.50 to \$15.75; and in Richmond, \$15.50. In setting this price scale, after an extensive investigation by Health Department inspectors, the committee pointed out that the price of coal to the retailers is \$9 for the long ton, the freight costs averaging about \$2.79 and the cost of local handling about \$2.08. The coal is sold by the short ton, and this, with 75c. added to allow for deterioration, would bring the price per short ton, as delivered to the consumer, to \$13.22. The margin allowed is held to be the legitimate profit of the retailer.

No action was taken by the directors of the Elk Horn Coal Corporation at their meeting last week on the dividend on the preferred stock. The corporation reports for the ten months ended Oct. 31 net earnings of about \$204,000. A preferred dividend of \$99,000 was paid this year, leaving a balance of \$105,000 to be carried to surplus. Output for the first ten months was 992,883 tons, as against 738,627 for the same period last year.

NORTH DAKOTA

The proposed advance of freight rates on lignite from North Dakota into Minnesota has started a general fight. The State Railroad and Warehouse commissions of North and South Dakota have protested against the increase, and have been granted a suspension to permit a hearing. The North Dakota body has also asked the Interstate Commerce Commission for a joint conference on the petition of the railroads for an increase. Lignite operators have entered their objection and declare that the raise would kill the lignite business. They state that 75 per cent of the lignite mines would be closed if the increase is made.

OKLAHOMA

A recent traffic agreement between the Joplin & Pittsburg Ry. Co., and the Northeast Oklahoma Railroad Co., together with the recent completion of physical connection between the two lines, made possible the **first transportation of coal directly from the Pittsburg field to the Oklahoma zinc field, Nov. 9.** On that day six cars of coal were moved from Crawford County to Columbus, Kan., over the Joplin & Pittsburg and from Columbus to Picher, Okla., over the Northeast Oklahoma.

PENNSYLVANIA

The Bertha-Consumers Co., of Pittsburgh, at a cost of \$500,000, has completed installation of shaker screens, picking tables and loading booms on the tipples of all its mines, together with storage-battery locomotives for gathering purposes. John H. Jones, president of the company, who, accompanied by his son, Marshall J. H. Jones, has just returned from an inspection tour of the properties, is very optimistic concerning future business conditions and looks for continued prosperity during 1924.

The Philadelphia Division of the **B. F. Sturtevant Co.** will be located after Nov. 19, 1923, at Thorne & Copewood Streets (near White Horse Pike and Haddon Avenue), Camden, N. J., in a modern daylight building, with railroad siding. The new shop will manufacture all kinds of sheet-metal work required for the complete installation of fan systems including heating, ventilating, drying, exhaust, and conveying work. Guards for machines, pulleys, and gears also will be manufactured. Standard equipment such as electric propeller, monogram, and planing mill fans, steel pressure blowers, turbo undergrate blowers, blast gates, etc., will be carried.

The first steps of the Reading Company to comply with the decree of the U. S. District Court in divorcing its coal business from its railroad business was taken last week, when an application for approval of a merger of all the railroad corporations of the company was filed with the Public Service Commission at Harrisburg. The Reading Company, as the holding company, controls the Philadelphia & Reading Railway Co. and twelve other underlying companies. The merged companies will be known as the Reading Company, and the commission will hear the application Dec. 5. The company contemplates forming another holding company for the coal and iron business, independent of the railway company.

Harry B. Henderson, referee for the Workmen's Compensation Board in the Pittsburgh district, **has resigned,** effective Dec. 1. Dr. Royal Meeker, Secretary of Labor and Industry, has appointed Charles F. Pearson, of Pittsburgh, as the successor to Mr. Henderson.

Leroy Coal & Mining Co., Youngwood, has been incorporated to mine, transport, purchase and sell bituminous coal with a capital of \$20,000; Incorporators are Logan G. Harrold, treasurer; L. W. Blackburn and N. L. Miller, Youngwood.

T. F. Quinn, president of the Quinn Coal Co., **has obtained a long-term lease on the Consolidated breaker of the Hillside Coal & Iron Co.,** below Moosic. He will prepare coal from his own mine in the section at the leased operation. The Consolidated mine has been worked out, officials of the Hillside company announced.

John Carr & Sons, Inc., Irwin, has been incorporated to mine coal and such other minerals as are incidentally developed; capital \$10,000; incorporators, James E. Carr, North Irwin, treasurer; John Carr, North Irwin, and John S. Carr, Irwin.

The Hudson Coal Co. has instituted a school for mine officials. Twenty young men have been employed by the company to study the various phases of mining. The course will cover a period of two and a half years, and the students, most of whom are college graduates, will be given positions of official capacity at the completion of the course.

Louis Hamer will be purchasing agent of the Hazle Brook Coal Co. after Dec. 1. Stores of the firm are located at a number of towns, including Hazle Brook, Maryd, Mid Valley, Park Place, Buck Mountain and Upper Lehigh. Mr. Hamer will succeed Guy Watson, who has resigned after five years' service in the position. Mr. Hamer's office will be located in Hazleton.

The Scranton Coal Co. has placed its West Ridge colliery on the market at a price of \$200,000. The mine has been idle for the past two years due to severe water conditions. It is reported that negotiations for the sale of the operation are now under way.

UTAH

The Pittsburg Boiler & Machinery Co. has purchased the plant of the Salt Lake Iron & Steel Co., at 540 West Seventh South St., Salt Lake City. Announcement of future operations include the building of complete equipment for coal fields and the erection of tipples. The company plans to spend \$500,000 on enlargement of its plant.

The Wyoming-Utah Coal Co., a Scofield corporation, has been adjudged a bankrupt in the U. S. District Court. S. T. Corn, of Salt Lake City, has been appointed referee. The company filed a petition in voluntary bankruptcy.

WEST VIRGINIA

The Fordson Coal Co. has acquired the title in fee to between 5,000 and 6,000 acres of coal land lying west and north of Davy embracing the Twin Branch operation and tracts, leased by the Fordson company several months ago. The purchasing company obtained the property and title from the J. B. B. Coal Co. and William B. Wheeler, John Gilbert and others, as trustees of the Lasher estate, of Philadelphia. After the Fordson company leased the J. B. B. property a short time ago it began to make many improvements, repainting houses, building sidewalks and erecting a club house.

After denying on Nov. 16 the motion of counsel for William Blizzard, placed on trial for participation in the armed march of 1921, for a change of venue, **Judge Sumners H. Sharp** in the Circuit Court of Greenbrier County, on Nov. 20, after making a further investigation **granted the mo-**

tion of the counsel for Blizzard. Choice of another county in which Blizzard shall be tried was left to attorneys in the case for agreement. When the attorneys were unable to agree on a county to which the Blizzard case should be transferred, Judge Sharp designated Fayette County.

The tax program adopted by the West Virginia Manufacturers Association at its annual meeting at Huntington calls for the imposition of a **service tax of 1 per cent on the sale value** at the mouth of the mine of all coal produced in the state, the proceeds of the tax to be used for the maintenance of the state constabulary, miners' hospitals and the mine inspection bureau.

F. A. Scott, of Fairmont, has completed arrangements to **purchase the mine of the Stone Lick Coal Co.,** located about two miles from Weston. The new owner plans, it is understood, to install all new mine equipment and expects to mine coal on an extensive scale.

The Big Vein Anthracite Collieries, Inc., **has closed negotiations for the purchase** of the mining operations of the Superior Anthracite Corporation on Brush Mountain, at McCoy, the consideration being \$225,000. The deal becomes effective at once.

A large tract of high-grade coal in Webster County, in the Eagle and Sewell New River series is being developed by the **Holly Elk Coal Co.,** organized by Clarksburg business men and capitalized at \$350,000. A. C. McIntyre is president; George W. Lynch treasurer and Walter M. Elliott secretary. Levi Keister is superintendent in charge of development work. Progress is being made in getting the mine ready for operation. The coal will be shipped over the Baltimore & Ohio, as a line from Centuria is now being graded and will be extended four miles up Elk River.

B. A. Lindeman, of Chicago, having resigned as president of the Fairmont Mining Machinery Co., **O. A. Seyferth,** of Fairmont, has been chosen to succeed him. C. R. Burt, of Toledo, has been elected vice president and director of the company.

R. T. Hubbard, of Fayetteville, has been appointed by the Circuit Court of Fayette County **as receiver for the Gaymont Coal Co. and the U. S. Pocahontas Coal Corporation,** which operates the old Gaymont mine near Hawk's Nest on New River. The court has also enjoined W. A. Ohley and others from selling the property under distress warrants or executions. The property has been under the direct management of W. A. Cravner. The president of the Gaymont Company is Jean F. Smith, of Huntington, who also is a creditor to the extent of \$50,000. Other liabilities are said to aggregate to \$75,000. The Gaymont mine ranks as one of the oldest on New River. There is a leasehold of 1,345 acres involved, on which a royalty of 10c. per ton is paid. Not more than 300 acres have been so far mined.

With a view to furnishing more power to the mines in the territory reached by it the **Appalachian Power Co. is installing its third 20,000-kw. turbine** as well as additional boilers at its Glen Lyn steam plant. When the improvements are completed the plant will have a capacity of 58,750 kw., or nearly 80,000 hp., which added to the hydro-electric development of the company of 28,000 kw., or nearly 40,000 hp., will give the company a total plant capacity of approximately 130,000 hp. Four boilers are being installed.

With the completion of its new plant and tippie at Concho, the **Rock Lick Smokeless Coal Co. has begun the production and shipment of coal.** The new steel tippie built by the Kanawha Manufacturing Co., has a daily capacity of more than 2,000 tons. It is so equipped that lump, slack, egg, three quarter lump and mine-run may be loaded. The tippie also is equipped with the necessary safeguards for the men working on and about it. C. H. Mead, one of the leading coal men of southern West Virginia, is president and general manager of the Rock Lick company.

WASHINGTON, D. C.

George H. Cushing is completing a two-weeks' speech-making tour of the Northwest, under the auspices of the National Coal Association.

F. R. Wadleigh, former chief of the fuel division of the Department of Commerce, has been appointed consulting engineer in the Bureau of Mines, effective Nov. 16. It is also stated, says a newspaper dispatch on reliable authority, that Mr. Wadleigh will receive a similar appointment in the Department of Commerce.

CANADA

Production of soft coal in eastern Canada during the first ten months of 1923 amounted to 4,363,737 tons, as compared with 4,259,366 tons for the twelve months of 1922, according to a statement attributed to the British Empire Steel Corporation. Premier Armstrong of Nova Scotia estimates that the production of coal in eastern Canada for the year will amount to more than 6,000,000 tons.

H. J. McCann assistant general manager of the Dominion Coal Co., has been appointed general manager. A. S. MacNeil has been appointed general superintendent of all the mines of the British Empire Steel Corporation, and Walter Herd chief mining engineer.

Charles Stewart, Minister of the Interior in the Dominion Government, recently proposed to the Government of the Province of Alberta that the province take over the supervision of fuel conservation work in conjunction with the regular inspection of mines to avoid the present overlapping between the two governments.

Those associated with the coal-mining industry in British Columbia have been interested in the recent reports of the efforts being made by Wm. Sloan, Minister of Mines, to induce the provincial government to place a sales tax on fuel oil used in British Columbia. Indications are the government will give the legislative assembly a chance to pass upon a small sales tax on all imported oil.

The Dominion Coal Co. has shipped its first coal cargo of the present season amounting to 8,500 tons to Holland, and it is expected that many other consignments will follow. Last year the company sent 125,000 tons to Rotterdam and negotiations for obtaining an increased contract are in progress.

The Newfoundland Coal Mining Corporation is being formed by Canadian and American capitalists to take over and operate the property of the St. George's Coal Fields, Ltd., says a newspaper dispatch. This property is located near St. John's, and is said to contain much high-grade coal. The new corporation will have \$5,000,000 capital.

Lieutenant-Colonel Charles Villiers has been appointed general manager of the Canadian Collieries (D) Ltd., to succeed the late J. M. Savage. Thomas Graham, who has been performing the duties of general manager temporarily, will continue with the company as general superintendent in charge of operations. Colonel Villiers formerly was assistant manager of the Johannesburg Consolidated Investment Co. He was for a time general manager of the African and European Investment Co., which controls several coal mines of the Transvaal. He also was with the Transvaal Chamber of Mines.

The "Coal Mines Regulation Act" of British Columbia is to be amended at the session of the Provincial Legislature now in progress to provide that all cases of ignition of gas or dust underground, all cases of fire underground, all cases of breakage of ropes, chains, or other gear by which men are lowered or raised, all cases of overwinding cages, all cases of inrush of water from old workings and any other dangerous occurrence shall be reported to the Inspector of Mines. At present this is not obligatory unless someone is injured, fatally or otherwise, as a result. Penalties also are to be substantially stiffened.

These officers of the Canadian Institute of Mining & Metallurgy (Vancouver Island Division) were elected in annual meeting at Nanaimo, Oct. 31: Chairman, Charles Graham, general superintendent, Canadian Collieries (D) Ltd.; vice-chairman, Charles Campbell, general superintendent, Granby Coal & Coke Co.; secretary-treasurer, Wm. H. Moore, Western Fuel Co., of Canada; Executive Committee, George O'Brien, Cumberland; Robt. Henderson, Nanaimo; Charles Touhey, Cassidy, and T. A. Spruston, Ladysmith. An address was given by Hugh F. Marriott, of London England; who was passing through the province in the course of a tour of the Empire. He explained that he was working on the organization of an Empire Federation of Mining Engineers, that he had visited South Africa, Australia and New Zealand with success and that he wanted general co-operation in making the Empire Exposition of next year in London an outstanding event in point of its mineral exhibits to the end that it might lead to a closer union and a better understanding in the mining engineering profession throughout the Empire with respect to the development of mineral resources.

Trade Literature

"The Kites Tail," a new publication issued for the automotive department of the Colonial Supply Co., 217 Water Street, Pittsburgh, Pa. The booklet contains profusely illustrated descriptions of transmission equipment designed to stabilize this portion of plant operation and reduce production cost.

Storage-Battery Locomotives. Mancha Storage Battery Locomotive Co., St. Louis, Mo. Pp. 19; 9x10 in.; illustrated. This book contains some very useful data on the different phases of haulage and should prove especially attractive to mine superintendents. In describing the Transfer Rack on the last page mention is made that by furnishing an additional battery and box the capacity of a locomotive is increased 100 per cent.; the transfer is made in three minutes.

William Ganschaw, president of the Williams Ganschaw Co., Chicago, Ill., is editing a new handbook on gears and speed transformers which will be combined with the forthcoming Ganschaw General Catalog No. 100. It will be sent upon request.

Traffic News

A phenomenal increase in coal loadings from the Logan, eastern Kentucky and other fields along the line of the Chesapeake & Ohio has made the creation of a new division of the Chesapeake & Ohio with headquarters at Russell necessary. The new division has been created primarily to facilitate the movement and handling of coal freight through the yards at Russell, Ky. W. S. Butler, heretofore first assistant to the general superintendent, E. L. Bock, has been appointed superintendent of the new division. As showing the heavy volume of traffic moved over the Chesapeake & Ohio westward, the daily average forwarding of loads west from Russell in October was 1,808, establishing a new record. In September a record had been established with daily average movement west of 1,798 cars. The management of the road has announced that on Oct. 13 a single shift operating on Pier No. 9 from 7 a.m. to 3 p.m. dumped 228 cars of coal or a total of 10,472 tons, as against a previous record of 205 cars on June 11, 1923.

Questions involved in the matter of Western coal rates will be considered at an Interstate Commerce Commission hearing in Salt Lake City Jan. 10. The case of the Cameron Coal Co. vs. the Santa Fe will be considered at the same time. Examiner Pattison will preside.

The Car Service Division of the American Railway Association says that on Nov. 1 freight cars in need of repair totaled 150,624, or 6.6 per cent of the total number owned. This was a decrease of 5,013 under the number in need of repair on Oct. 15, at which time there were 155,637, or 6.9 per cent.

During the month of October there passed through the Canals at Sault Ste. Marie, Michigan and Ontario, according to the report of L. C. Sabin, superintendent, 2,031,084 net tons of soft coal and 200,600 net tons of hard coal. Of this tonnage all but 31,365 tons of soft coal passed through the United States Canal.

The Interstate Commerce Commission has set for hearing Dec. 13 at 10 a.m., at Kansas City, the complaint brought by the Western Petroleum Refiners' Association against the Missouri Pacific R.R. for lower rates on fuel oil in competition with coal. The hearing will be before Examiner Shanafelt. It was previously assigned for Oct. 31, but postponed on application of complainant.

The Superior Coal Co., of Wheeling, W. Va., has filed a complaint against rates on coal from Chandler, Ohio, to Akron, Ohio.

The American Railway Association announces the removal of offices of the car service division and Bureau of Railway Economics to the Transportation Building, Seventeenth and H Streets, N.W., Washington, D. C., Effective Nov. 15, 1923.

Complaints have been filed with the I. C. C. attacking coal rates from Ziegler, Ill., to Lake Preston and Miller, S. D.

The freight rate on coal from Russellton, Pa., to Youngstown, Ohio, has been found not to be unreasonable. The rate was attacked by the Republic Iron & Steel Co.

Freight rates on lump coal in earloads from mines in western Kentucky on the Illinois Central and the Louisville & Nashville to Marianna, Ark., are not unreasonable, the Interstate Commerce Commission has ruled in a case brought by certain consumers of coal in Marianna.

Class 1 railroads, which operate 90 per cent of the country's rail mileage, earned \$92,238,400 during September, according to estimates prepared from Interstate Commerce Commission reports by the Bureau of Railway Economics. This total was said to represent an annual return rate of 4.46 per cent on the tentative value of property owned by the roads. It compared with earnings of \$58,677,600 made in September of last year and \$98,343,200 earned last August. For the first nine months of 1923, the bureau said, railroads earned a total of \$718,948,600, which represented an annual return rate of 5.27 per cent on the tentative value of railroad property and compared with \$529,470,680 during the same period of 1922.

A new high record in the amount of freight carried was made by the railroads of the United States during the first nine months this year, say reports by the Bureau of Railway Economics. The freight traffic for that period amounted to 343,796,799,000 net ton miles. This was an increase of 2.79 per cent over the corresponding period in 1920, when the previous record, which amounted to 334,457,000,000 net ton miles, was made. Compared with the first nine months of 1918, when freight traffic was greatly stimulated by the war, the total from Jan. 1 to Oct. 1 this year was an increase of 4.86 per cent. For the month of September this year alone the freight business of the railroads of this country totaled 39,449,128,000 net ton miles, which was the greatest traffic for any September in history except in September, 1920, which exceeded it by about 33 per cent, and September, 1918, which was greater by about one-third of 1 per cent.

Fewer locomotives were in need of repair on Nov. 1 than there have been in years, according to a report by the American Railway Association. On that date the number in need of repair totaled 10,112, or 15.3 per cent of the number owned. This was a reduction of 397 below the number in need of repair on Oct. 15, at which time there were 10,509, or 16.4 per cent. The railroads on Nov. 1 had 54,080 serviceable locomotives, an increase of 489 since the middle of the previous month, while the number of serviceable locomotives in storage and ready to meet increased traffic demands numbered 2,517, or 30 more than on Oct. 15. During the last half of October, 21,989 locomotives were repaired and turned out of the shops, an increase of 2,666 over the first half of the month.

Authority to acquire and operate a branch line in Gibson and Pike Counties, Ind., to develop a coal property, has been asked by the Evansville, Indianapolis & Terre Haute Ry. Co. in its application to the Interstate Commerce Commission, the company points out that this facility is intended for use in the development of "an extensive field of commercially valuable strip-mine coal acreage, comprising from 20,000 to 30,000 acres with an estimated yield of 8,000 tons per acre of high-grade bituminous coal or an aggregate of from 160,000,000 to 240,000,000 tons. The acquisition is approved by the Governor of Indiana and by the Public Service Commission of that state."

Substantial reductions in the rates on coal from producing points in Illinois and Indiana to Mason City, Iowa, have been requested by consumers in that city, who use 600,000 tons of this fuel annually. An example of the reductions requested is the rate from Christopher, Ill. The present rate on lump coal is \$3.47. The Mason City consumers attempt to show that the rate should not exceed \$2.90. On fine coal the existing rate is \$3.29. The rate requested is \$2.65.

Coming Meetings

Second National Exposition of Power & Mechanical Engineering. Grand Central Palace, New York City, Dec. 3-8. Managers, C. F. Roth and F. W. Payne, Grand Central Palace, New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

West Virginia Coal Mining Institute. Annual meeting Dec. 4 and 5, 1923, Huntington, West Va. Secretary, R. E. Sherwood, Charleston, West Va.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 24

NEW YORK, DECEMBER 6, 1923

Number 23

Lingering Doubt

NO ONE is yet in position to hold unqualifiedly that interstate wage agreements between coal operators and the United Mine Workers are legal. The famous Indianapolis indictments in Judge Anderson's court have been dismissed, it is true, but the air has not been cleared of doubt. There are those who are decidedly of the opinion that the government has not changed its mind as to its original position.

Window-glass producers and hand workers in that industry entered into a wage agreement during the war to maintain wages at a certain level. Their contracts have been renewed from time to time. The federal government has haled them both into court on the charge of having violated the Sherman Anti-Trust law and last month the case was argued before the Supreme Court. In arguing the case Solicitor-General Beck said that the agreement complained of had been entered into for the purpose of enhancing prices and that it imposed *the additional cost of maintaining an industry which worked only a portion of the year*. Sounds much like the charge that is raised against the union coal-mine workers' contract, doesn't it? It furthermore suggests the necessity of forcing, some way, a clear-cut decision on the question of whether coal production, declared by the Supreme Court to be intrastate business, comes under the federal laws which affect interstate business, when producers and miners from two or more states agree on wage contracts. Perhaps a decision in the window-glass case will settle some of these debatable issues.

The New Competition

THIS year has seen the greatest advance in any twelve months in the substitution of oil for anthracite in household heating. A survey made by the anthracite operators shows in New York City alone more than 200,000 tons of anthracite annually replaced by oil in homes, apartments and office buildings. New England has been a fertile field for the oil-equipment people. The coal question in New England is mainly the question of prepared sizes of anthracite. The Northeast Yankee is looking for something cheaper for his furnace than \$16 stove coal; hence his willingness to try oil. Already fuel oil has replaced a large tonnage of soft coal in industry in that market.

The anthracite operators have taken hold of the situation. They are going to show the householder something better than oil and cheaper as well—the steam sizes. When everything has been said for the advantages of all so-called substitutes, one finds that on the points of cleanliness, convenience and reliability, anthracite plays second to none. In Philadelphia this week the anthracite operators begin a belated campaign to educate the public to the use of that neglected por-

tion of their necessary output, buckwheat, rice and barley. They have opened a Fuel Economy Exhibit, where will be shown all tried and tested ways of using these cheap sizes of hard coal. The householder will be shown full-sized equipment for utilizing small sizes costing at the mine from \$1.50 to \$3.50 per ton against \$9 for the customary stove coal.

The cost of equipping homes to use this neglected fuel is no more than to install oil. The results are certain to be more satisfying. There will never be a question of adequacy of supply or of insurance. Oil is not the ideal fuel for the home that it is commonly supposed to be. The present fever will subside and by promptly extending their educational exhibits to every large community in the East the anthracite operators may overcome the handicap of a late start. The hard shell of conservatism is cracked.

Congress and Coal

SO ACCUSTOMED has the coal industry become in recent years to having the threat of federal legislation sidetracked in Congress that it is by way of losing interest in the subject. As a subject for action by this Congress, coal must take its place with such live topics as taxation, bonus, wheat prices and the World Court. The prospects for new laws affecting coal are thus obscured, and many for this reason display no anxiety, even though they would deplore any steps toward federal control.

Fulminations against coal will be abundant this winter in Washington, but what we are interested in is the direction that will be taken by serious intentioned legislators. Two are likely, quite probable: Compulsory reporting of the facts on the coal companies' books, and a measure authorizing the President to assume certain control of coal production and distribution during national emergencies.

With respect to compulsory fact finding it is pertinent to point out that the National Coal Association has defaulted on its promise to the Coal Commission to institute voluntary reporting. Whatever excuse or reason be assigned, it remains a default and as such becomes added argument for federal compulsion. There is an important section of the National Association, largely represented in West Virginia, that is opposed to any and all manners of giving the public any facts with respect to its business. These men were primarily responsible for the institution of the Maynard case, and resisted for a long time the Coal Commission's efforts to collect facts. They are those who honestly believe that what they do is nobody's business, and in general they may be expected "to stand on their constitutional rights" in resisting all efforts in that direction.

Strangely enough the United Mine Workers is largely of the same mind, not caring to have the federal gov-

ernment probe too deeply into its affairs. The union will line up behind any program of resisting regulation of coal.

There are, on the other hand, many substantial interests, not all among the organized soft-coal fields, that if not actually favoring complete publicity of their business at least have no objection and will offer no opposition. The opponents are aggressive, hence we may expect the coal industry to give every indication of actively fighting whatever coal measure may be offered in Congress.

Neither of these two broad proposals is a panacea for coal ills, and compulsory fact finding will prove very expensive to the government and a disappointment to the public. Nevertheless, to neither can we find substantial argument in opposition beyond the general one that these proposals or any others, however harmless or ineffective, are but the opening wedge for more drastic regulatory measures. That argument is wearing thin. If the organized resistance of the coal industry can estop such a simple thing as an act to collect and publish currently certain facts about coal, then why cannot that same organized effort more easily prevent more drastic and obviously oppressive measures? The test of the good faith of the operators in going on record in favor of giving the public the facts will be their position on a federal law looking to that end, provided the issue is clearly drawn on that measure.

A Small Corner of a Panorama

STANFORD E. THOMPSON, in his unbiased report on production, of which we publish a part this week, lays stress on the danger of reducing the miner's capacity to earn by poor car supply, and he does not by any means exhaust the arguments against that practice. Much of the miner's disposition to go home early has arisen from the fact that he has become used to a low tonnage and cannot be induced to do more than has for many years been customary. That stint performed he does not see why he should not go home. Thus shortening the stride of the miner to a walk has developed in him a tendency to restrain himself from which he can with difficulty be aroused.

In his study of fewer men and more topping, however, Mr. Thompson lifts but a corner of the sheet, revealing only a small portion of the full panorama. He does not consider what he knows well, that miners go home when they have completed what they consider their stint, that they do not have cars ready always when the gatherers need them, that the problem of railroading is complicated by that fact. Furthermore, he does not recall the fact that the miners do not strike so much because their wages are lower than they ought to be but because they think they should have a rise in wages every so often and because they believe that a labor leader whose platform does not include such a raise is not earning his pay.

Mr. Thompson does not consider what every operator knows, that decisions ultimately rest on political considerations and not on wage earnings. So long as the politicians flaunt the facts and so long as the mine workers continue to win out on the basis of their power to coerce the country, arguments to the operators to give miners a chance to earn more, to go home earlier and to lay off, and so tie up the transportation system, and even to insist on being hauled and hoisted out to the detriment of coal haulage or at risk to their lives,

so long will the operator be indifferent. Some blame may be accorded to the mine executive doubtless, but so badly is he imposed upon that he is not prepared to take this loss, and so keen is the competition in union mines that if he takes it his mine is idle, his men are without work and he is made bankrupt.

LaFollette Performs Without Calder

SENATOR LAFOLLETTE has broken out again in an attack on the National Coal Association. He excoriates that organization for its large expenditures, but he does not attempt any comparison with the expenditures of the United Mine Workers, which spent more in salaries alone in six months than did the National Coal Association in a year for all purposes.

Senator LaFollette never has recovered entirely from the unexpected blow he received during the Calder agitation. After Senator Calder had obtained Congressional funds and Congressional support for his committee on the pretense that a study of reconstruction problems was to be undertaken, he launched into an investigation of coal. He thought it would be popular with the public and with labor. Mr. LaFollette was of the same opinion. A coup was sprung and the Calder legislative recommendations were referred to Mr. LaFollette's committee. The coal industry was pilloried to the entire satisfaction of Senators LaFollette and Calder. Just as each was pluming himself to receive the plaudits for their work, in stepped Samuel Gompers, who condemned in no uncertain terms the whole conception. The proceeding was dropped quickly. Soon thereafter Mr. Calder was pulled off the national stage by his own constituents. Mr. LaFollette returns to his attack on the coal industry sporadically, but his old-time enthusiasm has been lacking since the day Mr. Gompers testified.

Siphonic Pumping

SEEING that the siphon works on the principle that falling water will lift other water up a grade by the vacuum it creates, why not use the power of the siphon even when a pump is used? Frequently it is possible to extend the pipe far enough down the hill that the load on the pump will be reduced or even, as in those cases where the lift is less than twenty feet, entirely removed. When the pump discharges underground, extending the pipe line often may enable the siphon to pull or the pumps to drive the water over a second and lower eminence and so save repumping the water from a sump between two summits. Of course, the starting load of the pump would not be decreased but the running load would be, and that is important. Some care to free the line of air should be taken as also some precautions against air leaks, but what efforts are used to this end need not be as painstaking as those which would be taken where the siphon is to operate without a pump.

GIFFORD PINCHOT PITCHED his "compact" scheme for anthracite regulation to the governors last week. Silzer of New Jersey at the bat, hit it over the fence. Pinchot's outfield expects to have retrieved the ball by Dec. 13, when the game will be resumed. Meanwhile the sport writers of the daily press are "knocking" the sportsmanship of Pennsylvania's leader, suggesting that he clean up the tax, miners' law, and other matters at home before passing the buck to the other states.

How Swinging Chutes Are Applied to Thin Seams

In Advancing Face Along the Strike Coal and Waste May Be Delivered by Same Chute or by Two Entirely Different Chutes — Pros and Cons for Working up Pitch or on Level

BY ARTHUR GERKE
Waldenburg, Silesia, Germany

IN *Coal Age*, Vol. 22, pp. 487-489, I discussed the methods employed in the mining of thin seams with swinging, or bumping, chutes where stowing was not employed for the support of the roof. The purpose of this article is to describe the methods as modified when the places mined are stowed as they are worked, but, prior to discussing this matter, it seems advisable to give the reasons why on the Continent of Europe the practice of replacing coal with rock when mining is regarded as being of great importance.

These reasons are the frequent falls of rock in roadways worked without stowing, crushing of the coal seams, heaving of the coal floor, injury to the surface, heavy expenditures for timbering, loss of large quantities of coal in squeezed working places and roadways, the probability of mine fires, the risk of firedamp collecting in the goaf, the danger of extinctive atmospheres or water collecting in the extracted areas and pouring down on the men when working below them in other seams or in lower levels of the same seam.

BACKFILLING HELD ESSENTIAL TO LONGWALL

In many cases the reasons for backfilling will be found to be only indirectly connected with the working methods. Such causes are the possibility of damage to the surface, the scarcity of dumping room and the fear that the rock if dumped on the surface will burn and create a nuisance. An advantage incident to backfilling is that the pressure on the pillars is relieved along headings and galleries permitting them to be more easily kept open and the coal in them removed.

With the use of backfilling the removal of barrier or

safety pillars is expedited. The principal advantage, however, consists in being able to operate "broad" or "longwall" workings. "Broad work" usually is laid out as in Fig. 1, the working face being from 125 to 300 ft. long. This face usually moves forward in the direction of the strike, the line of the face following the full pitch of the seam. A swinging chute fixed directly in front of the coal wall serves to convey the coal mined down to the entry.

After a section is mined the swinging chute is moved toward the face so as to leave room for the storage of rubbish. This same chute is then used to take the waste, delivering it where needed. Men stand along this chute and throw the rubbish with a shovel into the section to be filled.

If the mining is to be done by a large gang of men and the roof, or hanging wall, as well as the floor or foot wall, are reasonably solid, a wave will be noted originating in the hanging wall and following directly the cutting of the coal. If the stowing is kept at an appropriate distance from the coal face and if the latter is long enough and is moved along at a quick rate, the coal will be loosened by the pressure and will be the more easily brought down.

To produce that particular effect the face must be of sufficient length or the pressure will not be produced or not be of sufficient force to be effective. These considerations, which apply to all systems of longwall work, have important essentials, the most important being to have as many men as possible in every section and to mine the coal as quickly as can be contrived.

To accelerate coal extraction a miner is provided for

FIG. 1—ONE CHUTE SERVES FOR COAL AND WASTE

With only one chute operation is continually hampered, especially in the early morning when many of the cars are filled with waste that should be unloaded promptly.

FIG. 2—TWO CHUTES USED BUT FEW MEN CAN WORK

With two chutes waste can be backfilled almost at any time, but, as the chutes are unloaded and loaded only at the extreme end, few men can be employed in driving any one coal face.

FIG. 3—UNSHORTENED CHUTES: FULL FORCE OF MEN

Here the chutes are laid at full length. Hence waste can be unloaded and coal loaded at any point. At various places outstanding walls may be built rapidly to protect the face.

every 12 ft. of face, and to him that part of the work is assigned. He has to break down the coal and do the timbering. After the coal has been removed from before the face, with the aid of the shaking chute a part of the mined section is filled. For that purpose another swinging chute is used which must be shifted every day if the work advances with sufficient rapidity, as is, of course, the intention. Thus the working face, measuring from 125 to 300 ft. in length, advances every day by the width of one cut—about 5 ft.—if the miners are first-class men and the haulage system does not delay loading. Where the miners are not up to standard they are used at timbering work, in which they soon become specialists.

CONCENTRATION SAVES ROOF FALLS AND TIMBER

Owing to the speed with which the coal is won, the action of the hanging wall in such working places noticeably improves; not only is the danger of the roof breaking down close to the face diminished but also the quantity of timber needed to protect the workmen is much reduced.

This method works well if the seams are not too close together and if the hanging wall, as well as the foot-wall, are reasonably solid. Otherwise, the traveling pressure will not exhibit sufficient force to bring the coal down and may break the cohesion of the roof beyond the working face. Furthermore, if this plan is to be found satisfactory, there must be layers of coal that can be cut with the pick. If these are not found and the coal is so hard that it is necessary to blast it, the mining will not go forward rapidly enough if a single swinging chute has to handle the coal and also the waste by which it is to be replaced.

In consequence, two chutes must be employed and the area kept open in front of the face will have to be both larger and longer maintained, and the result will be that more timber will have to be used. Another serious drawback to success with this class of work is the irregularity with which the backfilling material may be received. On some days there will be a scarcity of rubbish in the mines, unless exploratory headings are being driven. On other days only a small quantity may be wanted in the mine, and the surplus may have to be hauled to the surface.

This trouble can be avoided by introducing a second swinging chute parallel with the face, using it solely for shifting rubbish and restricting the use of the inner chute to the conveyance of coal. The front chute remains in place even after the coal in the cuts has been removed. It is then used for filling until the section where the second chute once stood has been filled. In the meantime the second chute is moved forward to be used for conveying coal during the mining process.

When using two chutes, filling may be done in different ways. Fig. 2 shows the method of filling in the rising direction, where the chute is shortened according to the advance of the filling. This method can be recommended where the roof is sufficiently solid and where, for some reason or other, only a few men are employed at the particular place being worked.

When the face is mined in accordance with Fig. 3 the filling chute always is of full length, and consequently miners or loaders can be located about every 30 ft. As the full length of chute is in front of the area to be stowed they can take the rubbish with a snovel out of the swinging chute at any point they

please. This allows advance walls of rubbish to be built at many spots simultaneously, which enables sufficient support to be erected in a short time, a great advantage where the roof is of insufficient strength to support itself over a large area. This method is of special advantage in thick seams.

It is obvious that the use of the second swinging chute increases the equipment, as also the labor cost, a drawback that is, however, more than counterbalanced by the advantages which the duplication confers. Should there be a lack of empty cars, the miners, instead of being unoccupied, can be employed in backfilling until empty cars arrive. Moreover, if no waste material is at hand the men can be employed to undercut and load coal. Thus all the men will be kept working, and to great advantage, because they will be occupied throughout the shift.

If a shaft or inclined plane is to be found near by, sections equipped with two chutes can easily be supplied with empty cars, because the emptied waste cars need only be conveyed to the foot of the working face for filling with coal. In most cases this assures a sufficient number of cars always being available. A still more important advantage in actual practice will be found in the better distribution of the work of backfilling.

At the end of the second shift whatever cars are empty will be taken by the timbermen for use in their work. During the night they load these cars with rubbish and in the morning at the beginning of the early shift these cars are full and need to be unloaded promptly. As fast as they are unloaded they are moved to the discharge end of the chute at the foot of the working face. Here they should be loaded promptly in order to get things moving.

The face is full of coal that the weight has broken down. It is ready to be loaded but would have to wait long if the use of the chute for coal had to be delayed till all the waste in the cars was completely dumped. With two conveyors working—one for waste and one for coal—cars loaded with waste can with minimum delay be brought to the foot of the coal chute, shortening the time during which the loading of coal is delayed.

Nor is this all; with the single conveyor, as the backfilling must be done in cycles and not in any sense concurrently, the line of backfilling cannot be offset and must for that reason be kept near the face. As a result, if coal is ready to load it must be loaded so as to set the conveyor over for backfilling. This may not be at all convenient, for the waste in the morning fills the cars, as they cannot be emptied because there is coal to load before the conveyor can be moved. Yet they must be emptied before there are cars to load the coal.

CAR STEALING UNLIKELY IF FILLED WITH WASTE

This is an interesting dilemma, only to be solved by having more cars than would otherwise be necessary or by leaving the backfill far behind the face. With two chutes this need not cause delay, for the second chute can be used at all times or all the time for conveying waste regardless of the conditions that may exist at the face. With rope haulage the use of a single chute is quite difficult, for the car supply is discontinuous and long waits may result.

If for any reason an unusual number of cars is needed for a working face, one or several trips filled

with waste toward the end of a shift may be directed toward the area being worked and can be emptied at the beginning of the following shift. It need not be feared that cars full of waste can be taken away by men of adjoining work places, as too often happens with empty cars, especially during night shifts, for the laborers and timbermen who work without sufficient supervision at night can make no use of such cars. With two chutes, therefore, waste is conveyed with far greater regularity than with one only, and time is saved in the end even though there is a loss in moving two chutes instead of one.

Where the joints of the seam run in the direction of the strike it would not be well to choose what is known as "broad work," as it would not be possible to utilize the joints in the mining of the coal.

It should be said that a further disadvantage in mining in the direction of the strike is that the seam often contains rolls where the coal thins and that there are other similar disturbances that affect extraction. As such displacements generally run more or less diagonally through the seam, the face exhibits this roll or spar as an open wound so long as it is being worked. At the point of disturbance excess pressure may be experienced, and often bottom must be lifted to make room for the swinging chute. As the work progresses, the pressure moves along the face and consequently an unusual quantity of timber is required and some damage is done.

Ways there are of meeting these difficulties. The stowing may be done with greater promptitude and carried nearer the face or the entry may be driven to the limit and worked on the retreat. But whatever may be done, wherever such rolls occur, there always will be interruptions and roof falls that involve much expense, these difficulties continuing until the place is finished.

SOME CONDITIONS FAVOR WORKING UPWARD

In such cases a method is employed with advantage which is based on the rising longwall system of earlier days but which is readily adapted to use with swinging chutes. It is true the inclination must be steep and the seam not too thin or the waste will be conveyed with difficulty. Fig. 4 illustrates this method in which the seam is worked in a wide breast and to the rise. In some cases the face is placed at a greater angle to the strike than is shown in Fig. 4, so as to increase the inclination of the chute.

In opening up the workings by this system one or two entries—one of which is shown in the illustration—are driven on the strike from the main tunnel by which the seam is approached from the shaft, which tunnel is not shown. At distances of 660 ft. or less, airways are driven straight up the pitch to an upper level, the interval between these places being twice that of the longest face it is purposed to operate.

It is not well to make any one face longer than 330 ft. The entries should be driven through to the limit before starting to open the faces, but this is not always done. The working of any or all the faces may start at the same or at any convenient time.

The working face is opened as follows: At the side of this airway a narrow cut is made from the entry. A second and shorter rise is made 15 ft. or more therefrom, the distance depending on the number of men available. The next rise is started at the same distance but is extended a shorter distance, and this is continued

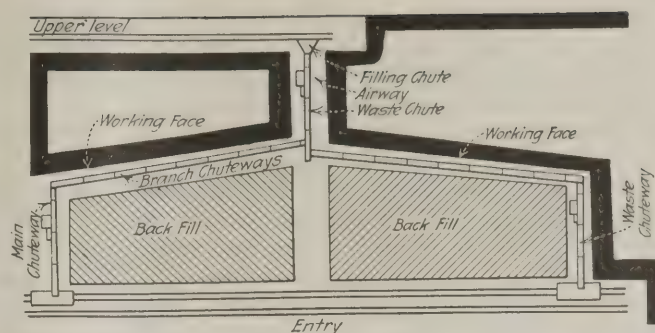

FIG. 4—WORKING THE COAL STRAIGHT UP THE PITCH
The waste and timber may be brought in from the upper level or may be hauled up the center airway by a hoist driven by electricity or compressed air.

until a point 330 ft. from the original chuteway is reached.

The faces of the various rises are arranged to be at an angle 8 to 10 deg. from the line of the strike. When this composite face has been completed a chute is placed in front of it, and work advances in the direction of the pitch. The coal may be conveyed to the entry in many ways, and the method employed in bringing in rubbish also may be varied. Of course, the waste need not be brought in if enough rock falls in the seam or if the rubbish need not be built up solidly.

In the method shown in Fig. 4 waste is unloaded from a car in the upper level into a filling chute by which it is conveyed to a swinging chute in the airway. By giving this chute less inclination than the full pitch of the seam the chute can be caused to deliver to either of the face chutes without the necessity for any excavation in the bottom of the seam. Thus the waste, as also the timber, is brought in from above. However, some bring it up the center airway on an inclined roadway in which the bottom must be lifted if the cars are too high to travel in the seam. A small hoist serves to pull up the cars.

As will be seen, the coal is dumped in a swinging chute in front of the face, which in turn dumps into another chute which descends at one end of the face from the face chute to the car at the entry. This chute may also carry the coal brought to it by the chute stationed in front of a neighboring face.

WHY ADVANCE TO PITCH IS AND IS NOT FAVORED

Thus by one working method two chutes and two small hoists worked with compressed air or electricity are needed. The costs that must be met in this method are saved by the other plans where the longwall is advanced in the direction of the strike and the face lies parallel to the pitch. Other disadvantages of the method with the hoist is that it is in itself objectionable as moving it is troublesome and expensive, that disturbances running in the direction of the strike cannot be evaded and that the maintenance of this inclined plane and of the air connection leads to expense. Replacing the chute also is difficult in a seam with much inclination.

Though these drawbacks cannot be denied they are compensated for by considerable advantages. In the first place the opening of the longwall is much simpler, for we can dispense with the roadways driven between the two levels to subdivide the area, thus saving the expense of maintaining them. If, however, a haulage road has been driven as an upper level we can dispense with the incline. If it is not necessary to bring in waste from other places or if the road for convey-

ing waste is high enough so that the cars can be tipped in it, then again an inclined road is not needed. As a result a number of men are relieved from unproductive work and much timbering is avoided.

Above all it must not be forgotten that by this method the output of the seam is increased in a comparatively short time. The longer the level the more places at which new longwall workings can be started. This makes it possible to concentrate production and consequently reduce the quantity of unproductive work more than is possible when the longwall is advanced in the direction of the strike. Needless to say the traveling pressure will exhibit itself here as in the other method and facilitate mining if the cutting is done quickly.

Each Fan Airs Part of Mine, but Either Can Relieve the Other

Royal Mine Protected by Automatic Doors That Open and Close When Either Fan Shuts Down, Giving All Workings Reduced Current

BY S. TESCHER

General Superintendent, the Royal Fuel Co., Denver, Colo.

NO FAN idles at the Royal Mine waiting, like an understudy, for the failure of the main fan. Two fans are kept busy, each ventilating its own separate area of the mine, and if one fails the other takes up the burden, the doors being hung so as to open or close when the direction of the current shows signs of changing. The fans thus relieve one another without reversing the direction of the current in the principal roadways. Returns remain returns, and intakes remain intakes. All the energy of the moving current is retained, and the air continues to travel with only slightly decreased volume and velocity. Thus the addition of a second fan means not only additional safety but more air without an equivalent power consumption.

This fan installation and a new airshaft were completed Sept. 1, 1923, by the Royal Fuel Co. at its Royal Mine, Aguilar, Colo. The installation gives this property two ventilating fans, each delivering air by a separate intake and a separate return to a different

section of the mine. By means of a bypass entry, which allows either of the two returns to go to either of the two fans, and by a system of doors and overcasts, either fan in case of disability can be made to ventilate the entire mine without any serious interruption to the ventilating current.

The new shaft has two compartments, the inside measurements of each being 9 ft. 6 in. x 9 ft. 11½ in. The depth of the shaft is 404 ft. The new shaft is located 1,600 ft. west of the present hoisting shaft, which is just that much closer to the working places.

The shaft is lined with 4x12-in. Oregon fir, tongued and grooved and surfaced on four sides, with the exception of a 22-ft. concrete collar at the surface and a 13-ft. concrete base near the landing. One compartment of this shaft is used as an intake or downcast, and the other is used as a return or upcast. The upcast compartment is connected by a steel housing to a double-inlet reversible Sirocco fan, which is driven by a 200-hp. motor equipped with a semi-automatic controller. The new fan can be started or stopped from the hoist house, where a man is in attendance 24 hours per day.

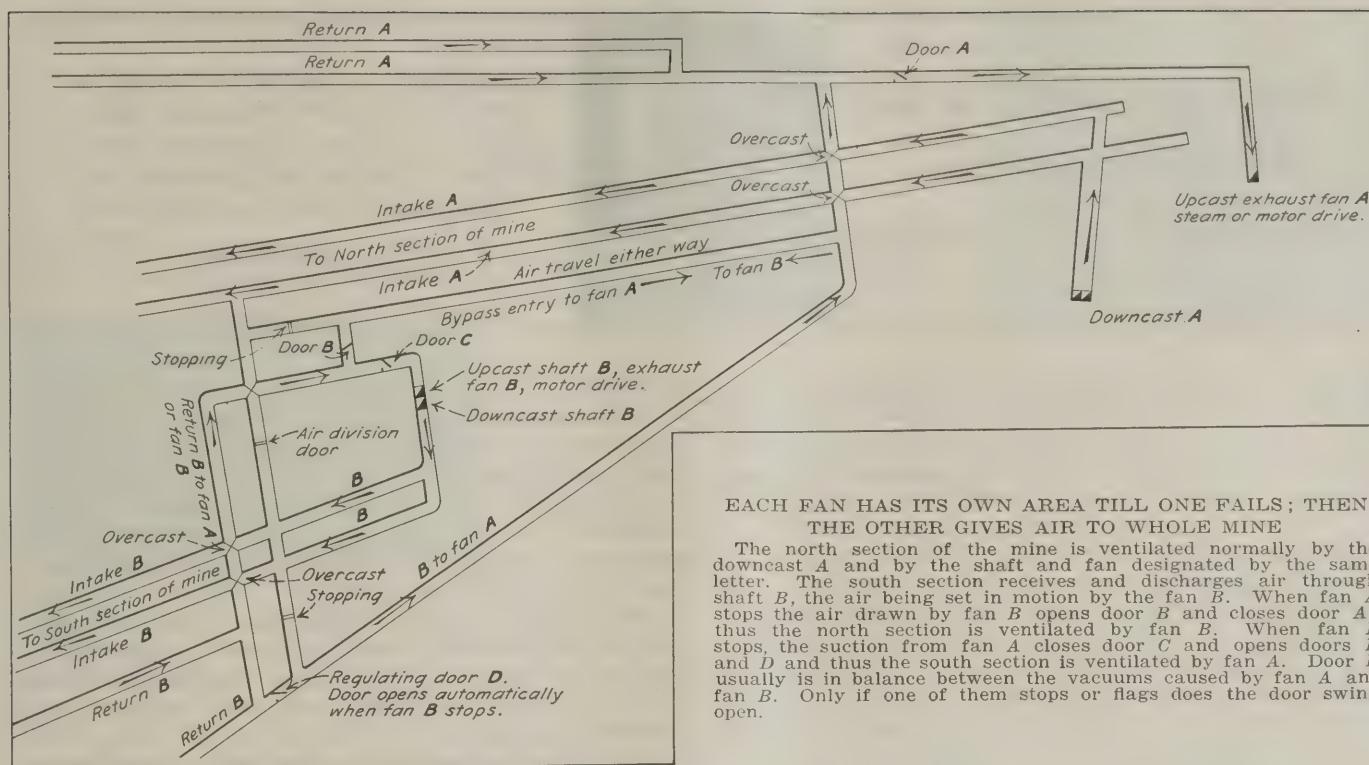

An automatic signal system rings a bell at the hoist house as well as in the mine, if the fan stops or its speed is reduced to any appreciable extent. The motor driving the fan is of ample size to take care of any overload and will keep the fan in operation under single-phase current.

Prior to the installation of the new fan and airshaft the old fan, which may be operated by either steam or electricity, ran at a speed of 300 r.p.m., consumed 107 hp. and delivered 96,000 cu.ft. of air per minute at a 4.5-in. water gage. Since the installation of the new fan the old fan has delivered 85,000 cu.ft. of air per minute to its section of the mine at a 3.7-in. water gage, it being driven at a speed of 270 r.p.m., and consuming about 75 hp.

The new fan, running at a speed of 250 r.p.m. and consuming about 75 hp., is delivering 100,000 cu.ft. of air per minute to its section of the mine at a 3-in. water gage. In other words, the total quantity of air coursing through the mine has been practically doubled, though the power consumption has been increased less than 50 per cent. To have doubled the quantity of air coursing through the mine without some such change

PANORAMA OF THE ROYAL MINE AT AGUILAR, COLO., SITUATE

EACH FAN HAS ITS OWN AREA TILL ONE FAILS; THEN THE OTHER GIVES AIR TO WHOLE MINE

The north section of the mine is ventilated normally by the downcast A and by the shaft and fan designated by the same letter. The south section receives and discharges air through shaft B, the air being set in motion by the fan B. When fan A stops the air drawn by fan B opens door B and closes door A; thus the north section is ventilated by fan B. When fan B stops, the suction from fan A closes door C and opens doors B and D and thus the south section is ventilated by fan A. Door B usually is in balance between the vacuums caused by fan A and fan B. Only if one of them stops or flags does the door swing open.

in the system such as provided would have been impracticable, as it would have required over 800 hp.

Gas analyses taken at three different points on the return aircourses prior to the new installation gave 0.9, 1 and 1.5 per cent methane respectively. Gas analyses taken after the new installation at these same points gave 0.4, 0 and 0.6 per cent methane, respectively. The absence of methane in the second sample is due to its having been taken out of the intake air before that air had entered the mine far enough to be contaminated.

Tests made at the mine after the new fan was installed show that if the new fan is stopped, the old fan automatically picks up a portion of the load of the new fan. On one occasion the new fan was shut down for 30 minutes. At the end of that time changes were made which allowed the old fan to ventilate the entire mine, and mine officials reported no change in the most

gaseous working places. The changes consumed about 15 minutes and were made, as stated, without a total stoppage of the ventilating current.

In the planning of this new ventilating system the direction of the air in the mine was in no place changed. This proved to be an important factor, as the air travel is aided by differences in temperature. The two fans are now capable of delivering over 250,000 cu.ft. of air without overloading their present driving equipment.

Four important factors entered into the improvement of the ventilation as above outlined: Shortening the distance of air travel by locating both the new intake and new return closer to the working faces; reducing the total volume of air passing in the old intake and old return by dividing the mine into two sections; placing of two additional splits in the air current; and installing an additional ventilating fan.

IN THE MOUNTAINOUS REGION OF LAS ANIMAS COUNTY

Profit Sharing Plan in British Coal Mines Simplifies Wage Problem

Coal Age Correspondent Finds Enterprise No Longer Penalized—Labor Now a Partner—Workers Interested in Effecting Economies—Change in Attitude Toward Machinery

By PAUL WOOTON
Washington Correspondent of *Coal Age*

DESPITE its popularity among operators in South Wales, the old sliding scale of wages, based solely on the price of coal, is not desirable, I learned from discussion with students of this subject in Great Britain. They believe that profits form a better basis on which to determine the amount the industry can afford to pay labor.

Under the sliding-scale plan the tendency was, for the wage to decrease as the output would increase. Rather than work themselves out of a job, the coal diggers were inclined to withhold their best efforts. In most cases the result was to penalize their enterprise. On the other hand, the sliding scale worked out inequitably for certain mines, particularly those where the relative cost of production was high. The rate of pay was uncertain and the men had little interest in avoiding waste.

By ascertaining what the operation can afford to pay, and by basing the wage on the profits, labor becomes a partner in the enterprise. Experience in Great Britain has been that the interest of the men in effecting economies is aroused at once. A workman who is wastefully inclined is held in check by his fellows. The plan is beset with difficulties, but none of them is regarded as insurmountable. Each month is seeing some progress in the effort to iron out these difficulties.

VIEWPOINT CHANGED ON MACHINERY

Under the profit-sharing system, labor occupies a different viewpoint with regard to the use of coal-cutting machines and other mechanical devices which make for economy in mine operation. They increase the profits of the men. The best authorities on coal in Great Britain believe that a material increase in the use of labor-saving devices may be expected from this time forward. There are physical reasons, however, which will preclude the use of cutting machines to the same extent that they are used in the United States.

England and Wales have a great asset in the fact that most of their miners are of British birth. Poles and other foreigners have been introduced into the mines of Scotland with resultant troubles. Experience there as well as in the United States has convinced British operators that it is wise to seek their labor at home. As it is, the mine worker in England is a substantial citizen. He has ideas and opinions of his own. He reads and is well versed in the trend of public affairs. As a result he is not led far astray by false prophets. He is willing to play the game and there is strong sentiment for living up to all agreements.

There is no hope that accord ever will be reached as to what constitutes a fair minimum wage, a feature of the coal treaty, which, in the words of Prof. James A. Bowie, of the Manchester School of Technology, "was thrust like a ramrod into the delicate mechanism of the

agreement at the last minute." Despite Professor Bowie's caustic criticism of the agreement itself, which he describes as imperfect and superficial, he nevertheless is outspoken in his belief that the principle which the agreement attempts to apply is sound. In fact he declares it to be "the most hopeful and comprehensive experiment in industrial relations that has been made during the present century." He calls attention to the fact that the coal agreement of 1921 comprises the first definite democratic pact in the history of the British coal industry, "embodying objectively the subjective principles on which collective bargaining had confusedly worked."

The operators are convinced that the minimum wage is too high and the men believe it is too low. The lack of accord is understandable, however, since employer and employee always have had divergent views on that subject. The minimum wage is the most troublesome feature of the present agreement, but there is little danger that it will wreck it, as some have predicted. The fact that the plan is an arrangement within the industry and is not handed down from above appeals to both operators and men. The scheme is proving to be a splendid antidote for socialism, which had gained a considerable following among British workers.

In discussing employer-employee relationships with this correspondent, a titled Englishman made the point that labor once was the slave of the master. The world progressed and the laborer became a wage earner. Another epoch now is dawning, this Englishman declared, in which the laborer becomes a profit-sharer. This is the secret, he thinks, of restoring productivity.

SCIENTIFIC LOAFING PASSING

Formerly labor became much more efficient during periods of unemployment. Since the war, however, the existence of large masses of unemployment has not tended so decidedly to such a result. The sentiment which governs in non-profit-sharing industries is one prompting the men to do as little as is possible in order to make way for more workers. The viciousness of such a policy is apparent in nearly all trades. Costs have been inflated to the point where production is limited greatly, with the result that unemployment continues on a larger scale than otherwise would be the case.

All of this has a direct bearing on the world coal situation, since the abnormally low industrial demand in the United Kingdom forces more British coal on the export market in competition with American and other coals. Moreover, the situation is one that is encountered in the United States with each dip in the curve representing industrial activity.

Next week Mr. Wooton writes of labor and labor leaders in the British coal industry.

Too Many Miners—What That Means to Themselves, The Operators and the Public

Well-Topped Cars May Save a Cent or Two per Ton in Haulage but May Make an Eighteen Cent Increase in Mining Rate Equitable

AT ONE of the mines visited by the engineers of the U. S. Coal Commission the general superintendent, who had charge of a number of large mines, stated that notwithstanding the fact that the miners were at present losing time waiting for cars, he planned to raise his output by increasing the number of loaders 50 per cent, thereby cutting down still further, by 33 per cent, the number of cars delivered to individual miners.

He said that in consequence of this proposed action the miners would be obliged to put more coal in the cars in order to earn the wages they were receiving, and with better filled cars the haulage cost would be lowered. In these mines the men were paid by the ton and not by the car. Furthermore, if under the new schedule some of the miners were absent he could give some of those who were in, 50 per cent more cars, and they would readily make up for the tonnage of the men who were out. In this way he could maintain his production. He could do this, furthermore, without breaking the letter of the "square turn" agreement with the union.

BALANCE LOSSES OF MINER AGAINST GAINS

It is of interest to note the relative effect in money losses to the miner and in apparent gain to the operator of extreme topping of cars, that is, piling up the coal above the top by careful stacking of lumps around the sides. Although a special case, this is of interest as illustrating the general principles involved in delays in work which is on a piecework basis.

In the mine to which reference is made 85½ per cent of all the coal produced was being loaded in rooms by men who frequently waited for cars and were expected to top them to the maximum height, whereas 14½ per cent was being loaded by men working in gangs in entries where the company was pushing the work. There they received all the cars they wanted, the purpose being to get out a big piece-rate tonnage. These heading men were not required to top their cars. In order to simplify consideration of the subject the figures have been reduced to a basis of 1,000 cars, and assuming each car to hold one ton when topped, the results of

actual loading during a representative eight-hour day for these two groups of men are given in the following tables in order to show the loss in tons of production due to a failure to top to the maximum height. This is based on direct observation of one day's work, except that the actual number of cars and their capacity has been converted for simplicity in figuring into their equivalent of 1,000 one-ton cars.

It will be seen from this table that with the conditions existing in this mine, where the miners are in rooms frequently waiting for cars and where the management requires the miners to top their wagons, the cars loaded and hauled are topped to an average of 91 per cent of capacity. On the other hand, in entries, where the miner was not kept waiting for cars and was not required to top them, the miners loaded 200 tons less than the cars would have carried if topped to capacity. This is only 80 per cent of the topped capacity instead of the 91 per cent that obtains where the cars are loaded in rooms.

CHANGE DOES NOT APPLY TO ENTRY MINERS

The decrease proposed by the management in the number of cars delivered to each miner applies only to miners in rooms, as the men driving entries will still be given all the cars they need. Allowing for the separate loading of bug dust, which cannot be topped, and for cars partly filled when cleaning up a cut, it is fair to estimate that the cars in rooms will be loaded to an average of 97 per cent of capacity if the supervision is close and the miners are compelled to wait still longer for cars. With this assumption the total cost of haulage and hoisting labor per ton will be as shown in Table II.

From these figures it is seen that the extreme saving to the company between the conditions of giving all miners all the cars they can load without requiring

TABLE I—LOSS OF OUTPUT BY LOW TOPPING

Loading in Rooms			Loading in Entries		
No. Cars	Percentage of Maximum Topped Capacity	Loss in Tons Due to Failure To Top To Capacity	No. Cars	Percentage of Maximum Topped Capacity	Loss in Tons Due to Failure To Top To Capacity
167	100	20	0	100	0
528	95	6	71	95	3
174	85	26	413	85	62
87	75	22	485	75	121
25	65	9	10	65	3½
9	55	4	10	55	4½
8	40	5	10	40	6
998	91	92	999	80	200

Fifth installment of report on "Underground Management in Bituminous Mines" made by Stanford E. Thompson and associates to the U. S. Coal Commission. Previous installments may be found in the issues of Nov. 8, p. 691; Nov. 15, p. 733; Nov. 22, p. 773, and Nov. 29, p. 811. Other sections of this interesting report will follow later.

topping and giving all the miners less than two-thirds of their carload capacity and requiring topping is the difference between 29.5 and 24.5, the entry and the room costs, or 5c. per ton.

There is further indirect saving to the mine operator by decreasing overhead per ton with increasing production and also by increasing the regularity of operation, as already has been indicated. The maximum real saving in labor, as shown by the table, however, is only 1.5c. per ton. This direct saving to the management is offset not only by increased expense for track and timbering but by greater and more insistent demands by the miner for deadwork allowance, about which he is much more contentious when he has much idle time.

TABLE II—EFFECT OF TOPPING ON HAULAGE COST

	Present Arrangement			After Reducing Cars 33 Per Cent		
	Room	Entry	Total	Room	Entry	Total
Per cent of total mine output	85.5	14.5	100	85.5	14.5	100
Per cent of mine-car capacity loaded	91	80	89.3	97	80	94.5
Total haulage and hoisting labor cost per ton	26.0	29.5	26.5	24.5	29.5	25.0

This, then, is the saving to the operator. It is well to look now to the effect of such methods on the miner. He is faced with the unchangeable schedule of union rates under which the miner is paid the same rate per ton whether he can mine one, ten, or twenty tons. With an average loading of six 2-ton cars, or twelve tons per day, for which he is paid 84c. per ton, he earns under the conditions of present car supply, \$10.08 per day, but when this is reduced one-third or to four 2-ton cars, the maximum he can load in a day (allowing for the extra topping and ratio assumed) is only

$$4 \times 2 \times \frac{97}{91}, \text{ or } 8.53 \text{ tons.}$$

This gives him, at 84c. per ton, \$7.16 a day against the \$10.08 formerly earned. Thus he loses \$2.92 a day. If the tonnage rates were immediately corrected to make up to the miner the loss in daily earnings, as is indeed sure to come to pass ultimately, it would be necessary to raise the rate per ton from 84c. to \$1.01½. This would represent an increase in the cost of mining labor of 17½c. per ton against a saving in haulage labor cost of 1½c. per ton.

The superintendent, however, knows that the men are working under definite rates which by the union agreement cannot be changed prior to April 1, 1924. If the idle time of the men were directly reflected in costs, it is inconceivable that any company would adopt a policy which would result in increasing that loss. Eventually, however, this increased cost would be borne by the company in increased rates per ton, and in turn would be passed on to the public. Such things as these indicate the need of analyzing the costs of mine-car loading and haulage so as to reach just and scientific solutions of the questions which are of such major importance to the industry.

IN THE ANTHRACITE REGION rock is frequently being loaded by compressed-air shovels, thus removing from the shoulders of the miners the burden of mucking. The operation being purely mechanical there is no necessity to give the shovel spells for rest, which with manual labor are necessary and tend to stretch out so unduly that work is the exception rather than the rule.

Examination Questions Answered

Solutions to Queries Involving Ventilation Problems

QUESTION—What pressure will be required to pass 150,000 cu.ft. of air per minute in the following splits or airways: Split A, 8x10 ft., 3,000 ft. long; split B, 7x12 ft., 4,000 ft. long; split C, 8x8 ft., 2,000 ft. long. Find the horsepower on the air at the mouth of each split.

ANSWER—The solution of this question depends on the principle, in splitting air currents; namely, the quantity of air passing in each split is proportional to the potential factor of such split as determined by the expression $X = a\sqrt{a/s}$. For the sectional areas and rubbing surfaces of the several splits we have

$$\begin{aligned} \text{Split A, } a &= 8 \times 10 = 80 \text{ sq.ft.;} \\ s &= 3,000 \times 2(8 + 10) = 108,000 \text{ sq.ft.} \\ \text{Split B, } a &= 7 \times 12 = 84 \text{ sq.ft.;} \\ s &= 4,000 \times 2(7 + 12) = 152,000 \text{ sq.ft.} \\ \text{Split C, } a &= 8 \times 8 = 64 \text{ sq.ft.;} \\ s &= 2,000 \times 2(8 + 8) = 64,000 \text{ sq.ft.} \end{aligned}$$

For the several potential factors of these splits, we have

$$\begin{aligned} \text{Split A, } X &= 80\sqrt{80/108,000} = 2.1773 \\ \text{Split B, } X &= 84\sqrt{84/152,000} = 1.9748 \\ \text{Split C, } X &= 64\sqrt{64/64,000} = 2.0239 \end{aligned}$$

$$\text{Sum of potentials} \quad \Sigma X = 6.1760$$

The pressure-producing circulation is found by dividing the total quantity of air in circulation by the sum of these potential factors and multiplying the square of this result by the coefficient of friction, which gives for the unit pressure in this case

$$p = k \left(\frac{Q}{\Sigma X} \right)^2 = 0.00000002 \left(\frac{150,000}{6.176} \right)^2 = 11.8 \text{ lb. per sq.ft.}$$

The total horsepower producing the circulation is

$$H = \frac{150,000 \times 11.8}{33,000} = 53.6 \text{ hp.}$$

The power on the air at the mouth of each split is proportional to the potential factor for such split; thus,

$$\begin{aligned} \text{Split A, } 6.176 : 2.1773 : : 53.6 : x &= 18.90 \text{ hp.} \\ \text{Split B, } 6.176 : 1.9748 : : 53.6 : x &= 17.14 \text{ hp.} \\ \text{Split C, } 6.176 : 2.0239 : : 53.6 : x &= 17.56 \text{ hp.} \end{aligned}$$

$$\text{Total} \quad 53.60 \text{ hp.}$$

QUESTION—A rectangular airway is 6 ft. high, 12 ft. wide and 2,500 ft. long; what is the rubbing surface in square feet?

ANSWER—The perimeter of this airway is $2(6 + 12) = 36$ ft., and the rubbing surface is, therefore, $2,500 \times 36 = 90,000$ sq.ft.

QUESTION—What is the maximum distance required by the mine law, for crosscuts to be from the working faces of chambers, headings and airways?

ANSWER—The law requires (Art. 10, Sec. 15) that headings or crosscuts shall not be driven more than 60 ft. from the face of each chamber or breast.

Washer That Removes Refuse in Coal as It Travels

Raw Coal Is Swept by Water Along Troughs—Slate and Bone Stratify Out and Are Trapped in Slots Which, by an Upward Current of Water, Are Kept from Admitting Coal

By JOSEPH KERSTEN*

Consulting Mining Engineer, Brussels, Belgium

THOUGH coal is washed in many ways, in all of them gravity has its effect. When a body falls in space that is filled with a fluid—liquid or gas—the velocity of its descent is diminished by the resistance of the fluid to displacement, and the denser the fluid the greater is this resistance. As the density of water is 800 times that of air, this diminution in velocity is of no little importance, in fact it may be calculated that the speed of the falling, or sinking, body rapidly reaches a maximum, after which its downward velocity becomes constant.

But the size of the falling particles also influences the velocity of sinking and in consequence a particle of any given specific gravity may fall at the same rate as one of a totally different specific gravity provided the size is such as to compensate for the difference in density.

Mathematical calculations show that during the first part of the fall, during which the velocity is accelerated,

FIG. 1—ONE REASON WHY THE SLATE IS TRAPPED

In sketches A and B are shown pieces of coal and slate respectively. In actual practice the slate would be working its way near the bottom of the trough. Here, however, both are at the same level. The coal, being cubical, gets the full sweep of the current and is less disposed to fall than the slate because of its low specific gravity. Consequently the resultant of the forces on the coal is more nearly horizontal than the resultant of the forces on the slate. Furthermore, the coal is moving rapidly as it approaches the slot and the slate is not, and hence, as in the Emery picker, the coal ignores the slot and passes on.

the particles are sorted, or, as it is technically termed, classified, according to specific gravity, but during the period of the fall at constant velocity, the speed of the descent depends not only on the specific gravity but on the size. When these two elements compensate one another, the classification is according to equal settling qualities, or "equivalence," as it is termed, and not according to specific gravity. This is a consideration that must not be overlooked.

Of course the sorting according to specific gravity is the only separation that will divide the coal satisfactorily according to its ash and pyrite content. A means of separation known as the Rhéolaveur (Ray-oh-lah-ver), or flow washer, has been devised by A. France-Focquet, of Liège, Belgium, that depends on the separation of coal and refuse in the first period of settling, in which the particles are accelerating and during which the classification is according to specific gravity and not affected, at least in so great a degree, by the size of the particle as it would be in the latter part of

the settling process, when the speed of the particle has reached its maximum and is no longer accelerated. Owing to the separation being effected in the manner indicated, close screening, such is customary in ordinary washers, is not necessary.

The raw coal is run by means of a current of water through an inclined trough, in which it is submitted to two forces: (1) An impelling force due to the motion of the water and (2) a retarding force due to friction of the particles. If 0.4 and 0.6 are taken as the coefficients of friction of coal and slate respectively, and the specific gravity of coal and slate are taken as 1.3 and 2.4, it can be proved by mathematical calculation that when coal is washed by horizontal currents of water no useful purpose is served by screening with openings the diameter of which bear a relation to each other less than 6 to 1.

When, however, coal is washed by upward-moving currents the screening should be in ratios of 2 to 1. Thus in treating raw coal from $\frac{1}{8}$ in. to $4\frac{1}{2}$ in. by the Rheolaveur, it is necessary theoretically to size the coal only into grades running between $\frac{1}{8}$ in. and $\frac{6}{16}$ or $\frac{3}{8}$ in., between $\frac{3}{8}$ and $1\frac{8}{8}$ or $2\frac{1}{4}$ in., and between $2\frac{1}{4}$ in. and the larger size, namely $4\frac{1}{2}$ in. With a washer using only upward currents coal should be divided into sizes running between $\frac{1}{8}$ in. and $\frac{1}{2}$ in., $\frac{1}{2}$ in. and $\frac{3}{4}$ in., $\frac{3}{4}$ in. and $1\frac{1}{2}$ in., $1\frac{1}{2}$ in. and 1 in., 1 in. and 2 in., 2 in. and 4 in., or with less exactitude $4\frac{1}{2}$ in. This makes it necessary to separate the coal into at least six sizes with upward currents of water and into not more than three sizes with the washer being described, and even such a degree of sizing can be still further diminished with the modifications to be described later.

Coal has been washed for many years in inclined troughs, the Elliot and Blackett washers being especially well known. The first is composed of a trough about 70 ft. long inclined on a slope of about 1 in. to the foot. Down this trough runs an endless chain fitted with scrapers. Raw coal is fed about half-way down the trough, the water being run in at the upper end. The clean coal carried along by the water passes over

FIG. 2—CASCADE BATTERY REWASHES COAL

Little irregularities in washing may make commercial coal pass through the slot with some of the inferior coal. That being so, only coal of superior excellence is allowed to pass direct to the clean-coal pipe. The rest is allowed to fall with the bone coal into another trough, where it is washed again. There the absence of slate and superior coal makes it easier to classify the clean coal and bone coal into their proper classes.

*Translation by Amand Andry, Secrétaire de la Maison France-Focquet, 17 Quai Saint-Léonard, Liège, Belgium.

FIG. 3—ILLUSTRATES THE CLOSED CYCLE IN WASHING

The bone coal, discharged at the end of the third trough, is given yet another trial. It is delivered with the feed to the head of the first trough and plays a valuable part in the primary classification by putting a barrier between the slate and the clean coal.

the scraper, which moves in the opposite direction to the water screen. Thus the slate is scraped to the upper end of the trough.

On the other hand the Blackett washer consists of an inclined cylinder the internal surface of which is fitted with a spiral. The cylinder is rotated and fed with coal and water at the upper end by means of a trough which extends an adjustable distance into the cylinder.

The water carries the clean coal to the lower end, and the slate and other impurities are conveyed backward along the spiral and discharged at the upper end of the cylinder. Such washers do not by any means produce a perfect separation; the motion of the scraper and of the spiral so disturbs the water in the washer that classification is hampered.

The Rhéolaveur consists of a trough of sheet metal, cast iron or reinforced concrete, as desired, inclined at the upper end of a gradient of 1 in 10 or even of 1 in 5, the slope being diminished gradually till it is only 1 in 20 at its lower end. In the bottom of this trough are cut at intervals orifices beneath which are placed special boxes divided into two compartments and having adjustable orifices for the extraction of slate. Into the troughs, water is fed under a head of 20 ft. or less. The coal, whether round or cubical, is transported freely by the water along the trough, but the slate, being relatively flat, moves at much lower speed and lags behind the coal. In consequence the feed sinks in the water and is classified according to specific gravity. As it is carried along the classification continues.

The particles of slate are deposited first and form a natural slope inclined in the direction of the stream. When this slope has reached a certain sufficient inclination the particles of slate are carried along by the force of the water, but quite slowly because of their shape and of their friction on the deposited material.

If a simple slot were made in the bottom of the trough at that point the particles of slate would fall through it, as also the water and coal; consequently in order to keep the water and the coal within the trough, an upward current of water is produced by a special device known as the Rhéolaveur box, which allows the slate to fall but does not disturb the classification or allow the water or coal to leave the trough. If the bed of slate is sufficiently thick and the slot correctly placed, only a slow upward current will be required to sustain the coal and bone. In these boxes is also a downward current which facilitates the discharge of the slate from the box. The pressure of the water is regulated

by a valve and the extraction of the slate by conical apertures.

The upward current also has the effect of pushing the lighter particles above those that are more dense, thus preparing the slice of slate for extraction at the slot following.

The classification progresses as the feed continues along the trough until the last slot is reached. Here the bone coal, or middlings, is discharged. The whole process is so regulated that at the end of the trough nothing is left but commercially pure coal, and for this purpose the last boxes are arranged so as to extract a product containing some commercially pure coal which is to be re-treated, as will be explained later. Thus all the dense particles must reach the bottom of the trough before they arrive at the last box. This is why the slope of the trough is diminished toward the end and why no upward current is provided in the last slot.

Dams also are arranged in the bottom of the trough, the object of which is to retard the flow of water and increase the friction of the slate.

It has just been said that the product extracted by the last box is to be rewashed, and accordingly the washer is arranged as in Fig. 2, which shows what is known as a "cascade battery."

In instances where the washing of the product is unusually difficult, a considerable number of successive washings could be provided. To guard against this inconvenience, the scheme known as "rewashing in a closed cycle" has been devised. This rewashing consists of conveying back to the head of the plant the product carried to the end of the rewash trough by means of a suitable elevating conveyor (see Fig. 3). This product consists, of course, of particles of specific gravity greater than coal and less than slate. When introduced into the feed it forms a sort of artificial barrier be-

FIG. 4—FLOW SHEETS FOR THREE KINDS OF COAL

The coal of which Diagram 1 is the flow sheet is of normal character. The sheet marked Diagram 2 is for cleaner coal and diagram 3 is for a dirtier coal than the other two. Only one box in the last case discharges clean coal, only two in the first case and three in the case of the cleanest coal of all.

tween the pure coal, which is light, and the pure slate, which is dense. Moreover, whenever the composition of the feed varies, the thickness of the slice of intermediate products, or bone, also varies accordingly, and it is easy to realize that this forms a layer preventing the purer coal from being mixed with the slaty material.

To explain this arrangement more clearly, Diagrams 1, 2 and 3 in Fig. 4 are given to outline the principal conditions which occur in washery practice. These diagrams show also the various percentages by weight of commercially pure coal discharged by the different boxes, depending on the proportion of shale contained in the raw material.

In Diagram 1 the first group of boxes work with a weak upward current of water, and shale with 2 to 5 per cent of commercially pure coal falls through them

FIG. 5—SEALED CHAMBER FOR LARGE COAL

Large coal requires so big a slot that the trough would empty if no provisions were made to prevent it. So a flap is arranged which opens and closes and so sustaining the level of the material in the trough.

to the rewashing trough. Those of the second group operate without the addition of any water and the commercially pure coal contained in the shale increases progressively from 10 per cent till the last two boxes pass what is practically commercially pure coal.

In this manner the coal delivered at the end of the trough is of the purity needed for marketing purposes. All the apertures in the second trough are supplied with upward currents of water so as to prevent any of the commercial product from being extracted with the slate. Of course, some of the product passing over the end of the second trough contains some bone, but this is of no importance because this product is to be washed the third time.

Diagram 2 shows the method adopted where the feed is cleaner than in Diagram 1. In this case there are three boxes in the upper trough which discharge pure coal. Where, as in Diagram 3, the feed is dirtier than in Diagram 1, only one box in the upper trough discharges pure coal.

It is easy to realize that in all three cases the bone is rewashed in the upper trough and consequently can be entirely extracted as the rewashing permits the re-treating of any products leaving the lower trough. The above considerations apply to the washing of fine coal from 0.01 in. to 0.3 or 0.4 in. in diameter.

In washing coal from 0.3 or 0.4 in. in diameter the principle is similar to the washing of fines. The regulation of the upward current, however, would require too much care, as the slots would necessarily be rather wide to pass the largest particles.

The trough for treating large coal is shorter than is used for fines, because the former is more rapidly sorted than the latter. The whole plant usually consists of one trough fitted with two chambers, the first of which extracts slate and the second discharges a mixture consisting of the bone and some coal. This mixture is elevated to the head of the trough and forms a sort of barrier between the clean coal and the slate, just as has been said occurs in the washing of fines. Where many flat particles of slate are found in the feed it is easy to extract them by the second chamber

with a reduced upward current or with none whatever.

With a device of this character it is possible to wash coal from zero to 2½ in. without any preliminary screening. Fig. 8 shows such a washer. The first trough has two sealed chambers, the first of which extracts pure slate and the second a mixture to be rewashed, as already explained. The trough discharges the clean coal, which passes on to a screen which extracts particles from zero to 0.2 in. in diameter. These are re-washed in one or two troughs fitted with free-discharge boxes. The fines are drained by a special drainage scraper which compresses them and thus extracts some of the water.

That is why, in this case, use has been made of an apparatus known as "*à niveau plein*,"* or sealed type of box directly connected to the boot of a sealed bucket elevator. These boxes are fitted with an oscillating flap, and owing to these provisions the slate is extracted without any loss of water whatever. The flap oscillates between a horizontal position which nearly closes the slot and a more or less inclined position, according to the aperture which the size of the largest particles may require.

In order to prevent such a complete extraction of the slate as would make a break in the bed of slate and let the pure coal pass down, the slot has been replaced by a chamber which works almost like a classifying agent. When the flap opens, a stream of water strikes the slate. The slate drops through the flap but any particle of coal that may be associated with it is driven upward and prevented from falling through the trap. Thus is avoided the suction which has had so undesirable an effect in the operation of a jig. When the flap closes much the same result is attained as by a stroke of a jig (see Fig. 5).

The chambers also have been fitted with a moving vertical flap which makes it possible to regulate the aperture through which the slate is discharged from the chamber (see Fig. 6). With these appliances coal from ¼ in. to 4 in. can be treated.

When the raw coal to be treated is dry, it is often advisable to extract dust from zero to 0.02 in. before washing. This is done by means of a pneumatic dust extractor or by vibrating tables. This extremely fine dust can be mixed wholly or in part with the washed fines. In this way it is possible to prevent the formation of coal slimes.

When the raw coal is wet, it is better to wash it all, regardless of its fineness. If, after washing, the particles between zero and 0.02 in. are clean, it is well to provide means of settling this fine material, large hoppers being provided for that purpose. If, however, the fine particles are somewhat dirty, it is desirable to eliminate them from the washed fines and consequently smaller hoppers will suffice, so that these extremely fine particles will be discharged wholly or partly with the waste water.

FIG. 6—SEALED CHAMBER WITH VARIABLE OPENING

In this case a wheel is added, the movement of which enlarges or diminishes the aperture.

*Having the opening filled level [with deposited material].

FIG. 7—ARRANGEMENT FOR WASHING COARSE COAL

Here are only two traps, one for slate and one for bone coal. Only one trough is provided, and the bone from the second trap is rewashed with the feed.

Sometimes it is better to settle all the fines in hoppers and before storing them in bins to rinse them with the clear water from the elevator by which the washed fines are conveyed. Provision is easily made for this by fitting the chute with a fine screen on which clear water is sprayed. The slime thus withdrawn is collected in V-shaped hoppers.

THREE PRINCIPLES USED IN WASHER DESIGN

This type of washer therefore is based on the following principles: (1) The raw coal is submitted to the action of a horizontal current of water in a rectilinear trough of which the length, shape and slope are designed so as to provide as perfect a separation as possible. In this the coal progressively receives its primary classification. (2) The heavy particles systematically and progressively deposited on the bottom of the trough are extracted by an extremely simple device which not only removes the slaty material but at the same time assists the primary classification by utilizing upward currents of water, the velocity and direction of which are arranged so as adequately to effect the desired result at each phase of the classification. (3) By treating the heavy discharge of the first trough in a second immediately beneath it, the loss of valuable coal is avoided. Sometimes a third trough is used to rewash the heavy material evacuated by the second.

If there is a change in the quality or quantity of the material to be washed, the rewashing of the bone coal in a closed circuit introduces an averaging of these variables. Thus the cascade battery smooths out irregularities in feed just as the flywheel compensates for the inequalities in power output and outgo.

The bone when being rewashed acts as classifying

agent, making an artificial barrier between the coal and the slate which prevents any of the coal from mixing with the slate and being drawn out into the refuse. By the closed circuit the quantity of bone in the raw feed is supplemented by bone from previous washings and in a short time becomes sufficiently deep to make a layer of bone through which the coal cannot pass at any of the boxes by which slate destined for the rockpile is drawn.

The advantages of this type of washer are a reduction of the percentage of carbon lost in the slate, a reduction in the quantity of slimes to be handled, less capital investment, less power consumption (for a jig will require 2 hp. per ton-hour capacity and a Rhéolaveur only 1 hp.), greater efficiency, a saving in water circulation and consumption, less attendance and labor and lowered upkeep cost.

In conclusion the method of determining the character of coal to be rewashed may be reviewed. A series of liquids are prepared of different specific gravities, as, for example, 1.2, 1.3, 1.4, 1.5, 1.6 and 1.7. A sample of dried coal is weighed. It is then put into the liquid of a specific gravity of 1.7. What sinks is dried, weighed and burned to ash. What floats is put into the next liquid in the series, which has a specific gravity of 1.6. What sinks is dealt with as before. The float is successively put into the whole series of liquids and from the liquid at a specific gravity of 1.3 both sink and float are dried, weighed and burned to ash.

With the figures thus obtained a diagram can be drawn showing the washability of the coal and the results to be sought. In practice the Rhéolaveur washer will come close to the figures thus obtained.

FIG. 8—PLANT TO CLEAN COAL UP TO 2½ IN.

The coal, cleaned over two traps, one for slate and one for bone, passes to a trammel. The coarse coal goes to storage bins, and the fine coal is rewashed by a cascade battery like that shown in Fig. 2.

Compiled by Ore & Coal Exchange, Cleveland, Ohio: H. M. Griggs, manager.

Connections Between Meters And Transformers*

Instantaneous Polarities of Terminals—Properly Connecting Meters—Tracing Instrument Cable Wires—Following Circuit in Complicated Diagrams

MUCH confusion often results when endeavoring to properly connect meters and instruments to electric power circuits; especially is this true on switchboards using the same instrument transformers for meters and relays. There are several methods of checking these connections but many of them are so elaborate that they are impractical for everyday use. When wiring up wattmeters and watt-hour meters it is necessary that the current and potential coils be connected so that the flow of current at every instant is such as to produce proper direction of rotation or deflection of the meter.

With simple single-phase circuits not using instrument transformers it usually is rather easy to make the proper connections, but when transformers are used on polyphase systems where the meters are wired to the instrument transformers through wires passing through conduits the problem is sometimes quite difficult.

FIGS. 1 AND 2—POLARITY MARKING ON INSTRUMENT TRANSFORMERS

In painting the framework and equipment behind a switchboard it is important to preserve these polarity marks on the instrument transformers; otherwise considerable confusion may result when making changes to the wiring.

One of the simplest methods of checking meter and transformer connections is by following the direction of the currents at a given instant. In order to do this it is necessary to know the instantaneous polarity of transformers, circuits and instruments.

INSTANTANEOUS POLARITY MARKS

With direct current it is assumed that the current flows from + to —; so if the polarity of a piece of apparatus is given the direction of current flow can be determined, and conversely, if the direction of current flow is given the polarity can readily be determined. The same rule holds true in alternating current, although both the polarity and direction of current flow reverse perhaps 50 to 120 times per second, depending on the frequency of the circuit. Therefore, in order to find out the relation of polarity and current flow in alternating-current diagrams, we pick out any particular instant and label the polarity at that instant, the "instantaneous polarity" with a + or —, and label the current at that instant, the "instantaneous direction of current flow," using a small arrow to denote the

direction. In the accompanying diagrams all the + signs may be changed to — and all the arrows reversed, yet the results will be absolutely the same.

Consider for the first case, an ordinary potential transformer. These devices usually have two primary and two secondary leads, and one of each will be painted red or white. The diagrams will appear somewhat like Figs. 1A or B. Since the primary *P* consumes power, if it is assumed that the polarity mark is +, then the direction of current at that instant will be as shown by the small arrows in Figs. 2A and B. The secondary *S* is acting like a generator of power, so with this polarity mark + the direction at that instant will be as shown by the little arrows on the secondary side. The same method may be expanded to a complete diagram and take the form of Fig. 3, which shows a potential transformer connected to a voltmeter.

MARKS ON WOUND PRIMARY TRANSFORMERS

When the current transformers contain a wound primary, thus having a total of four leads, the polarities are just the same as for a potential transformer. Many current transformers, however, have a hole through which a line wire may be passed to form the primary. These transformers will have a white or red spot painted on one side of the transformer at the end of the hole, thus denoting that at the instant when the current flows through the line wire from the polarity marked side to the opposite side, then the secondary current will leave the polarity marked lead and flow to the opposite lead. Fig. 4 shows the relation between polarity marks and current flow in this type of transformer.

Examining the instructions furnished by the manufacturer, a wattmeter diagram may be found similar to Fig. 5, and in order to most easily and correctly connect this in the circuit, it should be marked with the instantaneous polarities and direction of current flow. Assuming that the right-hand wire is + at a particular instant, then the small arrows in Fig. 6 will indicate the direction of current flow at that instant in both current and potential windings. Note that this manufacturer places polarity marks on the opposite ends of the transformers. If these polarity marks do not occur in the diagrams furnished, it may be assumed that these marks are both on the same end. Thus if Fig. 5 did not designate polarity marks, the instantaneous directions of current flow would be those of Fig. 7 rather than Fig. 6.

MAKING TWO-PHASE CONNECTIONS

Two-phase circuits may be treated exactly like two single-phase circuits, whether they employ four wires or three. If the two phases employ a common wire, then it may have two sets of arrows to show the current flow. These need not interfere even if pointing in opposite directions, as that condition simply means that the wire is carrying only the difference of two currents and does not interfere with the polarity or instantaneous markings in the least.

Three-phase circuits are also marked by assuming the polarities at any instant. There may be twelve distinct sets of instantaneous directions of current flow in a three-phase circuit, any one of which will work correctly, but for the sake of uniformity the instant usually assumed is when the current is flowing toward the load in the two outside wires and returning in the middle wire or neutral.

*Abstract of article by Victor H. Todd, engineer, Westinghouse Electric & Manufacturing Co., in *Power*, Sept. 11.

Consider first the manufacturer's diagram, Fig. 8, which is for a polyphase wattmeter. It is assumed that the outside wires are + and the middle wire —.

through the current coil of the wattmeter, which must correspond to the same phase as the potential coil, then over through the oil-switch trip coil, through the common wire and the ammeter back to *F*. In a similar manner, starting at *E*, the circuit is through the other current coil of the wattmeter, the other trip coil, ammeter and back to *F*. It will be noted that there is a common connection between the common connections of both the current and potential transformers, but this is for protective purposes and is usually grounded and does not carry any current in normal operation.

Many times wiring must be run in conduit, as the transformers may

FIG. 3

FIG. 4

FIG. 5

FIG. 7

FIGS. 3 TO 7—SHOW RELATION BETWEEN POLARITY MARKING AND METER CONNECTIONS
 Fig. 3—Instantaneous direction of current flow in a potential transformer. Fig. 4—Instantaneous direction of current flow in a current transformer. Fig. 5—Diagram for single-phase wattmeter and transformer connection with polarity marks indicated. Fig. 6—Same as Fig. 5, with instantaneous direction of current flow indicated. Fig. 7—Instantaneous direction of current flow when polarity marks are not given

Then the instantaneous directions of current flow are as indicated in Fig. 9.

For the foregoing simple cases, perhaps other systems of connection identification could be devised to work as well, and in fact the experienced instrument man would often not even require a diagram to hook up a meter correctly. But the greatest application of this system lies in laying out wiring diagrams for switchboards where perhaps ammeters, relays, power-factor meters and other devices may be all connected to the same transformers. Then the checker will set before this complete switchboard wiring diagram and, starting at the polarity mark on a transformer, follow the line through its maze of wiring, putting a little arrow at short intervals as he proceeds, until finally the line thus diligently followed ends at the opposite side of the transformer.

COMBINING INSTRUMENTS AND RELAYS

As an example of this consider Fig. 10, which is a diagram of an alternating-current panel with a wattmeter, ammeter and oil switch. For the potential circuit, first start at *A* and the line goes through the fuse, potential coil of wattmeter, fuse and back to *B*. Again starting at *C*, the path is through the fuse, other potential coils, fuse and back to *B*. Starting at *D*, of the current transformers, the path must ultimately come back to *F*. Therefore, from *D* the circuit is

be located at considerable distance from the switchboard or instruments. In such cases it is preferable to run two wires from the current transformers and make the common connection at the meter rather than at the transformers. A wattmeter diagram like Fig. 9 would then take the form of Fig. 11, where the wires are shown entering the conduit at the transformers and leaving at the meter.

Care must be used in identifying the wires as they enter and leave the conduit. One way is to ground one wire to the conduit at one end, and then at the other end pick out with a magneto, bell and battery or megger, the wire that gives a circuit through the conduit. Mark both ends with paint or tags so they may be easily distinguished. Then ground the next wire and identify it at both ends, and so on. This process is rather a long drawn out one, and there is always the danger of getting the markings mixed, which everyone familiar with this class of work knows. Furthermore, if the devices are disconnected, then it is a case of seeing that the wires are properly marked so that they may be connected up again correctly, and this is always a source of trouble. To overcome this difficulty, it is becoming general practice to use different colored wires for connections between transformers and meters.

Perhaps the easiest and best way to identify meter and instrument wiring whether it be in conduit or not.

FIG. 8—MANUFACTURER'S DIAGRAM FOR POLYPHASE WATTMETER CONNECTIONS

For construction purposes polarity markings must be followed consistently.

is to use wire with various-colored insulations. Cables may be obtained with either 2, 3, 4 or 7 different colored wires under one covering. For polyphase wattmeter work it is best to employ a 4-wire cable for the current and a 3-wire cable for the voltage. Many firms use 7 conductors for this, but often the potential transformers are located at some distance from the current transformers, thus entailing considerable skinning of insulation and waste of cable.

Now if a polyphase watt-hour meter is to be connected to transformers with the wiring in conduit, the diagram would appear like Fig. 11, where the instantaneous polarities, directions of current flow and colors of the wires are clearly marked.

This marking has been standardized by a large central station, and when meter wiring is encountered, every meterman can tell at a glance just which wires are potential and which are current; which wires feed and which return; and in this way it is easy to connect the meter correctly, and if one were connected wrongly, it would soon be detected.

In Figs. 8 and 9 reactors are shown in series with the potential coils of the wattmeter. The only time resistors are used in series with the potential circuit of a wattmeter or watt-hour meter is when the potential

current to lag sufficiently to give 90-deg. displacement between the current and potential fluxes. A resistor would tend to throw the potential current in phase, and the meter could not be calibrated on varying power factors. The meter and reactors are calibrated as a unit and must not be confused with multipliers. It is impractical to build a meter with a reactor multiplier, as such a reactor must have exactly the same characteristics as the potential circuit of the meter, and this is done only in rare cases.

Practical Pointers for Electrical and Mechanical Men will be found on pages 859 and 860; Problems in Underground Management on pages 861 and 862

News of the Industry

Pinchot Drafts New Plan and Compact To Regulate Anthracite Industry

Two Governors and Nine Delegates at First Conference Lukewarm to Scheme—Solution in Pennsylvania's Hands, They Say—Proposed Legislation Nearly Ready—To Meet Again Dec. 13

Governor Pinchot of Pennsylvania has sent to the governors of thirty states using anthracite a copy of the proposed compact of the states, suggested at the conference of the representatives of twelve states at Harrisburg, Nov. 26, together with the complete proceedings of that meeting. Within a few days he will forward to the same governors a copy of his proposed federal legislation, which, with the co-operation between states, provided for in the compact, he says, will bring about regulation of the anthracite industry and a reduction in retail prices.

As suggested at the first coal conference of the state executive, Governor Pinchot fixed Dec. 13, at 2.30 p.m., as the time for the next conference.

None of the representatives at the first conference displayed any enthusiasm relative to the compact. Governor Silzer of New Jersey and Governor Preus, of Minnesota, opposed it, as did the representatives of other states, on the ground that Pennsylvania should declare the coal industry a public utility, repeal the anthracite tax and the miners' certification law.

The Pinchot plan, the Pennsylvania Governor said in his letter transmitting the compact draft, is new and he added that it seems to him to be "sound tactics to try a new way," for at least it can be said "that it has not failed already." The plan is legally good, he said, and in his suggested plan he cited numerous instances of compacts between states and many court decisions to prove their validity. As a part of uniform control the compact will "have more effect than such legislation has ever had before," he wrote.

The points stressed by the Governor in his letter were that under the compact the coal business would be declared a public utility and this would be the basis from which two co-operating commissions would work to regulate the industry and finally to fix prices, among other things. There would be a joint commission of five members, if the United States does not ratify the compact, and of seven, if it does.

The compact also provides for a Pennsylvania Coal Commission which would consist of the Pennsylvania member on the joint commission—the compact providing that the anthracite state

be represented—who would act as chairman, the chairman of the Public Service Commission and the Attorney General of Pennsylvania.

The Pennsylvania commission would regulate the anthracite industry within

Governor Pinchot Outlines His Proposed Compact as Follows:

"The proposed compact will be an exercise of the constitutional powers of the states and of the United States.

"It conforms to established practice illustrated by a host of examples from 1784 to 1923.

"It will be identical legislation by the contracting states, which no one of them can repeal.

"It will insure unity of administration under this legislation, thus pooling the legislative and administrative power of the contracting states.

"If Congress so chooses, it will add to the pool the legislative and administrative power of the federal government over interstate commerce.

"If not, it will at least make co-operation by the federal government possible by giving it only one state authority to deal with.

"It will remove a doubt whether production by itself is a public utility which Pennsylvania alone can constitutionally regulate.

"It will insure investigation and publicity by an agency of the consumers as to all these stages of the business and as to mining in addition.

"It will insure the benefits of regulation to consumers by applying the regulation to every stage of the business from the mine to the consumer."

Pennsylvania in co-operation with the joint commission and the federal government. The joint commission would have power to fix prices after investigation and publication of facts. Its price-fixing power would commence after the sale of coal at the mines or after the coal leaves the mines. It would be expected to provide efficient service to the consumers, to prohibit discrimination, to provide equal distribution and would have power to pool profits and coal delivered. It would fix standards of size and quality, license dealers and otherwise regulate the trade.

In his draft of the compact Governor Pinchot outlines the proposed compact as follows:

In addition to Governors Pinchot, Silzer and Preus the others at the conference of Nov. 26 and the states they represented were: Major H. P. Sheldon, Vermont; Cyrus Locher, Ohio; James A. Hamilton, Connecticut; E. C. Hultman, Massachusetts; J. J. Rutledge, Maryland; George H. Webb, Rhode Island; J. R. A. Hobson, Virginia; W. E. Snide, Michigan, and Dr. F. J. Monaghan, New York.

Treadway Advises Repeal of Anthracite Tax

In a statement issued Nov. 28. Representative Treadway, of Massachusetts, called on Governor Pinchot to summon the General Assembly in special session to repeal the "\$8,000,000 tax levied against citizens of other states" using anthracite. "If a sufficient number of people," Mr. Treadway said, "continue telling Governor Pinchot where the first great fault lies, namely, at his own door, the fact may eventually permeate his brain. Unless he promptly sees the drift of the current, instead of impotently trying to row upstream against public opinion, he soon will find himself and his state laws in the eddy of stringent federal legislation."

Must Submit Rate Sheets to Mine Committee

The Anthracite Board of Conciliation, meeting in Philadelphia, Nov. 30. decided that all operators of the hard-coal fields must submit copies of their rate sheets to the mine committee at each colliery. This was provided for under the last agreement but in some cases owners of collieries have declined to permit sheets to be removed from the colliery office, asking that the mine committees go over the details at the office.

**SUMMARY OF RATES PAID TO COMPANY MEN IN ANTHRACITE MINES UNDER DATE OF
APRIL 1, 1923, AS REPORTED BY U. S. COAL COMMISSION**

Summarizing the outstanding features in the analysis of rates paid 53,159 company men under date of April 1, 1923, it is found that the significant range in rates varies from 27 to 71c. an hour. The bulk of the wage earners, approximately 88 per cent, received between 51 and 71c. an hour. Of the 10 per cent who received less than 51c., a little over three-fourths were boys.

Of the adult workers receiving 27 to 71c. per hour, 95 per cent received between 51 and 71c. A further refinement of the rates paid this 95 per cent shows that 19.1 per cent received between 51 and 53c. an hour, 5.5 per cent between 53c. and 55c.; 8.9 per cent between 55c. and 57c.; 5.9 per cent between 57 and 59c.; 15.6 per cent between 59c. and 61c.; 18.2 per cent between

61c. and 63c.; 6.1 per cent between 65c. and 67c.; 9.7 per cent between 67c. and 69c. and 0.3 per cent between 69 and 71c.

A comparison of rates in the three coal-producing regions shows that the inside workers in Schuylkill region received somewhat higher rates than similar employees in the Lehigh region. On the whole the inside employees in the Wyoming region received the lowest rates. In the case of the outside workers the highest rates are paid to the employees in the Wyoming region, the next highest in the Schuylkill and the lowest in the Lehigh region. There existed a differential between the rates paid inside and outside men which amounts to 8.1c. per hour in favor of the inside day men.

Pay of Anthracite Company Men Ranges From 27c. to 71c. an Hour

**Report of Coal Commission on Hard-Coal Wages Shows Significant
Variation in Earnings—Inside Workers in Schuylkill Region
Better Paid Than in Other Two Fields**

Wage rates in the anthracite industry are the subject of a report by W. E. Fisher, released by the U. S. Coal Commission last week. The report was prepared early in the summer and made available to the anthracite operators and miners during their wage negotiations. It was available also to Governor Pinchot at the time he granted the miners a 10-per cent wage increase.

Mr. Fisher's summary of his findings on hourly rates paid the company men, which constitute 60 per cent of the hard-coal workers, is given in full in the box at the top of this page. It is pointed out that the men employed as blacksmiths, carpenters, firemen, machinists and electricians at the anthracite mines work practically a full time year, and hence no attempt was made to compare their rates of pay with those of similar occupations in the building trades.

It is noted that the hourly rates in the Schuylkill region are higher than in the other two regions, and that irrespective of occupation or of region there is a differential of 10c. an hour in favor of the inside day men over the outside men. Mr. Fisher says, however, that "a weighted average lowers this differential to 8.1c. an hour in favor of the inside men."

"A presentation of the rates paid to tonnage men has been considered practically impossible," says the report. "As already explained, the contract miners and their laborers are piece workers. The units of work for which payment is made vary not only in the different coal fields but also from colliery to colliery, and even within different sections of the same colliery." The different methods of mining have necessitated different methods of wage payments.

The report studies the trend of wage

rates in the anthracite industry from 1901 to 1923 and summarizes the detailed studies by showing that the relative wage rates of anthracite contract miners have increased from 100 in 1902 to 213.6 in 1923, prior to Sept. 1.

The lack of uniformity and the wide variation of rates is shown in an elaborate series of statistical tables accompanying the report.

It was on the basis of this study by Mr. Fisher that the Coal Commission, in a report to the President on Aug. 23, 1923, following its unsuccessful effort to bring the miners and operators together for a new contract, said:

"The Commission reiterates its finding that there are inequalities and injustices in the present wage scale, not only in the entire anthracite district but even in individual localities and mines. It quotes for your information the following facts as found by its investigators, in proof of this statement:

"In one district, company miners are now paid fifteen rates in twenty-two mines and in another district thirty-eight different rates in sixty-five mines, the hourly wage ranging from 59.4c. to \$1.02. Similarly in the same districts, an outside occupation, like carpenter, may have thirty-seven different rates in twenty-two collieries, with a range of from 52.5c. to 72.7c. an hour, while in the other districts the maximum rate for the same job is 90c. and \$1. Similar variations in wage rates for the same job are found throughout the anthracite region, the same mine paying five, six, or even seven different rates for outside laborers.

"Even with the piece workers or tonnage men, the contract miners and their laborers, the rates paid in different mines cannot be directly compared. In one mine there is separate payment

for each item of additional work, such as setting props and laying sheet iron, while in another mine in the same district, payment for these items is included in the car or ton rate for coal mined and loaded. These differences in tonnage rates may also involve marked inequalities inherited from the more or less haphazard arrangements of rates which prevailed twenty years and more ago. And the marked differences in annual earnings of these miners are in part traceable to differences in rates. In the same mine, miners working the full year range in earnings from \$1,698.14 for 282 days to \$6,414.64 for the same number of days. In another mine, a miner earned \$4,471.88 in 283 days, while another working 5 days more, earned \$1,897.50. Or stating it in another way, the same earnings for different miners in another mine may represent as much as 53 days' difference in working time. Obviously, any flat percentage increase in rates would only further widen the spread in earnings of men rendering similar service.'

"Other instances might be supplied, but it is not necessary for the purposes of this report. They will be found in the special report on Wage Rates in the Anthracite Industry.

"The origin of these inequalities is found in the 1902 rate structure, which was without any scientific basis, since at that time wages and rates varied from mine to mine and even from working place to working place within the same mine. These different bases of pay and innumerable rate differentials then in force were crystallized in the 1903 award; and successive percentage increases have served simply to accentuate and increase the inequalities. The inequitable conditions surrounding this complex wage-structure are manifestly unfair to the individual mine workers, and the recognition of this led the Commission to make its recommendation above quoted."

Effective Dec. 1, D. E. Gelatt was appointed general coal freight agent of the New York Central R.R. with headquarters at 466 Lexington Avenue, New York City. The position of coal traffic manager was abolished.

Trade Commission Takes Up Madeira-Hill Case

Dec. 3, the first day of the hearing before the Federal Trade Commission in the Madeira-Hill case, was taken up largely with a review of the coal situation leading up to the specific events to be considered later. F. R. Wadleigh, formerly Federal Fuel Distributor, testified as to the location of the various coal fields and of the negotiations in connection with the voluntary establishment of fair prices.

E. S. Felton, former chairman of the Pennsylvania Fair Practices Committee, testified that prices suggested by that committee during the anthracite strike as reasonable for different sizes of coal were arbitrarily set, but neither Madeira, Hill & Co. nor any other producers were compelled to abide by the prices fixed by the Federal Trade Commission.

The anthracite situation is a matter of chronic worry in New England, the commission was told by Eugene C. Hultman, Fuel Administrator of Massachusetts. There is a permanent shortage of hard coal, he declared.

Electrical Engineers Meet In Anthracite Field

The Lehigh Valley Section of the American Institute of Electrical Engineers held its last meeting at Pottsville, Pa., Nov. 16 and 17. Considerable more interest has been given to meetings held in this region due to the importance attached to the electrification of mining equipment.

On Friday evening a dinner and business session was held at the Schuylkill Country Club. C. A. Grenidge, chief engineer of the J. G. White Company, explained many details with reference to the new Pine Grove power plant. Another speaker was William H. Lesser, electrical engineer of Madeira, Hill & Co., who spoke on the subject of electrification of the coal mines and gave records showing the progress of the work and the benefits derived in lower costs, higher efficiency and flexibility resulting therefrom.

Urge Dake for Coal Chief of Commerce Department

No selection for the position of chief of the Coal Commodity Division of the Department of Commerce has been announced at the time of this writing. It is understood that the names of J. D. A. Morrow, C. P. White, C. P. Starr and W. M. Dake, Jr., were suggested in this connection, but it has been ascertained that neither Mr. Morrow, Major Starr nor Mr. White is in a position to accept the place. Their other activities are such as to preclude their acceptance of the position even were they willing to make the financial sacrifice which would have to be incurred were any one of them to take the position.

It is not known whether or not Mr. Dake would accept the position were it tendered to him. Nevertheless he is be-

No One Held Culpable for Orient Explosion

The coroner's jury, after an inquest over the death of two men killed in explosion of Orient No. 1 Mine, West Frankfort, Ill., Nov. 26, held nobody culpable. The evidence showed that the examiner had approved the place three hours before the blast. A small roof fall meantime released a pocket of gas, which was ignited by the open flame lamp of one of the men who climbed over the fall. The thirteen injured men are all expected to recover. Damage to the mine was negligible. A 50-ft. barrier enclosing the panel in which the explosion occurred and a water-soaked haulage-way out of the panel neck combined effectively to stop spread of the blast.

ing urged strongly for the place. Objection to his appointment was raised in certain quarters on the ground that he formerly had been connected with the Federal Trade Commission. The report to that effect was without foundation. Mr. Dake never has been connected in any way with Federal Trade Commission activities. He is a mining engineer and his experience has been largely on the operating side of the industry.

Immigration Conference to Be Held in New York

The National Industrial Conference Board is arranging a conference on immigration policy to be held Dec. 13 and 14, 1923, at the Hotel Astor, New York City.

The Per Centum Limit Act of May, 1921, with subsequent amendments, which regulates the influx of most of the immigration to the United States, will expire by statutory limitation on June 30, 1924. Extension or modification of this act or substitution of a new law by Congress is therefore necessary.

This National Immigration Conference will give interested persons, in their individual capacity or as representatives of organized groups of society, an opportunity to express themselves on this important problem.

A cordial invitation is extended to all organizations dealing with economic and social problems to appoint delegates and to call the conference to the attention of their members in order to obtain their individual attendance and interest. The National Immigration Conference offers opportunity for co-operation in a most valuable public service.

Anthracite Rate Hearing On in Washington

Examiner Butler reopened the Interstate Commerce Commission's hearings on anthracite freight rates in Washington on Dec. 3 with a proposal to open to New England and North Atlantic states the soft coal produced in southern West Virginia.

C. J. Goodyear, traffic manager of the Pittsburgh Coal Producers' Association, testified that Pennsylvania could furnish all of the coal required as a substitute for anthracite in this territory. He further declared that it would be a waste of transportation to make rates from southern West Virginia that would provide for carrying coal all rail across the bituminous fields of Pennsylvania to New England.

Hoover's Year Book Is Out

Hoover's Commerce Year Book is off the press. It is a companion volume to the annual statistical abstract, which for years has been a standard reference book. The Year Book interprets figures instead of merely setting them forth.

Business is a great network of inter-related activities. The most effective conduct of any one of them requires a knowledge of trends in other trades. These are furnished in the Year Book. The initial volume covers the calendar year of 1922 and the first half of 1923.

A condensed summary of the broad conclusions based on the figures contained in the book follows:

"The year 1922 was one of marked recovery in industry and business, but agriculture still lagged in recuperation. The special impulse toward recovery, aside from the cyclic swing from acute depression, undoubtedly lay in the shortage of construction during the war and the stimulation given to other industries by the activity of the building and construction trades in the period which followed the war's close. Production of manufactured goods was one-fifth greater in 1921 and only slightly less than in the boom years of 1919 and 1920.

"The increased demand for goods led to an advance in prices, though far less sharp than the preceding drop from the abnormal levels of the war and the immediate post-war years. Wholesale prices for 1922 averaged only a trifle higher than for 1921, but the general index at the close of the year was 13 per cent above that at the beginning. The low prices of farm products during 1921 had been one of the contributing causes of the general depression of business. The prices of these products rose nearly 20 per cent during 1922, and this advance helped in considerable measure to restore the buying power of the great agricultural community and thus to promote general prosperity.

"The one important element in American business to fall off in 1922 was export trade, which declined both in value and in volume, as compared with 1921."

Effort at State Coal Control a Fizzle Is Washington View

Abortive Meeting of Governors Seen Merely as Part of Pinchot Political Program—Belief Is That Pennsylvania Would Dodge Anthracite Regulation but Continue to Milk the Industry

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

The effort of Governor Pinchot to obtain concerted action among certain of the states, looking to the regulation of the coal industry, is regarded in Washington as having been a fizzle. The failure of such a large proportion of the Governors invited to attend is as significant, it is held, as the inability of the meeting to agree on a program.

The tendency in Washington is to regard the meeting simply as a step in Governor Pinchot's political plans. Anyone with a grain of political sense, it is contended, must have known in advance that the meeting could not attain its ostensible objective. It did obtain wide publicity for dispatches associating Governor Pinchot's name with an effort to regulate the coal industry, and called attention again to the fact that he has declared war on the anthracite operators.

There is some amusement occasioned by the unexpected turn affairs took when it was suggested that the Pennsylvania Governor possesses all the authority necessary to impose regulation upon the anthracite industry. As one man put it, the Governor was bumped in the face with his own boomerang.

HARD TO GET JOINT STATE ACTION

The meeting accentuated anew the great difficulties of obtaining joint action on the part of individual states. Theoretically the states collectively possess all the powers of the federal government, but with Legislatures meeting at different times, with different political parties in control, and with the inertia which characterizes so many state administrations, there is little likelihood of getting results, even on a proposal as popular in states consuming hard coal as is the regulation of the anthracite industry.

Just at this time many bituminous operators are laying emphasis on the contention that the federal government does not have the power to regulate their business, particularly where sales are made at the mine. In that connection the thought is expressed that the day may come when they would prefer federal to state regulation. In the case of the railroads there was determined opposition to federal regulation. There was a feeling that the states would be more liberal to them. When the separate commonwealths really got into action, the railroads soon found that federal regulation was much to be preferred to state regulation. The activities of the state railroad commissions recently were referred to as being

"pestiferous" by a spokesman for the railroads.

In so far as anthracite is concerned, however, it is apparent that neither Pennsylvania nor Governor Pinchot has any desire to undertake the regulation of the production of anthracite coal. The expense of such an undertaking would exceed by many times any saving which might result to consumers in Pennsylvania. Moreover there would be objection to action which might interfere seriously with the functioning of one of the state's most important industries. The attitude of the people of Pennsylvania would be to pass the buck, in the matter of regulation, to the federal government and continue to milk the industry for heavy taxes.

Congress again is in session. It will be interesting to note whether the trend of sentiment in that body is toward the Federal Trade Commission-Interstate Commerce Commission type of profiteer-chasing regulation or toward the Department of Commerce-Department of Agriculture type of voluntary returns.

The failure of Governor Pinchot's meeting, however, will accentuate the impracticability of attempting regulation by the states and will be pointed to as evidence that the only alternative is federal regulation. Activity on the part of the coal trade in opposition to any form of federal regulation simply would play into the hands of the regulationists, many think.

Shipping Board Bids Show Upward Tendency

Bids were received and opened Nov. 28 by the U. S. Shipping Board at New York City, for furnishing and delivering alongside vessels, New York harbor, 2,300 gross tons of either Pool 9 or Pool 71 bituminous coal, delivery to be made Dec. 5. The following bids were received: Seiler Coal Co., \$4.91 per ton; Penn Fuel Co., \$5.09; Seaboard Fuel Co., \$5.31; H. B. W. Haff, \$5.60; E. Russell Norton, \$5.32; M. F. Shea, \$5.49; Dexter & Carpenter, \$5.22; Imperial Coal Corporation, \$5.67; Rhodes Fuel Corporation, \$4.80; W. A. Marshall & Co., \$5.35; Commercial Coal Co., \$5.44; B. J. Lynch Coal Co., Inc., \$5.69, and Knickerbocker Fuel Co., \$5.50. On a basis of net ton f.o.b. mine the bids received ranged from about \$1.57 to \$2.36, as compared with \$1.02 to \$1.97 submitted on Oct. 25, when bids were received for furnishing and delivering 1,800 gross tons of similar quality coal.

Soviet Coal Industry

Ten months of coal production in Russia are reported by the *Russian Review*, published by the Russian Information Bureau at Washington. During that time 9,734,259 net tons, or 539,100,000 poods of coal was produced. In July 153,500 men were employed who produced 50,800,000 poods, or 917,270 tons. This figures just a little less than 6 tons per man per month, or 72 tons per man per year. The fluctuation in the number of men between 133,600 in December, 1922, and 161,300 in June of the present year was due to insufficient and irregular payment of wages, agricultural work, etc.

Budget Increase to Geological Survey and Mines Bureau

The budget submitted to Congress on Monday by the President carries \$1,909,573 for the Bureau of Mines and \$1,805,272 for the Geological Survey. This represents an increase of \$139,873 over the amount appropriated for the current fiscal year in the case of the Bureau of Mines and an increase of \$135,082 in the case of the Geological Survey.

The amount recommended for the conduct of the work of the Bureau of Mines on investigation as to the causes of mine explosions and as to methods of mining having a relation to safety is \$359,768. This is \$33,232 less than the amount appropriated for the current fiscal year.

The sum of \$262,300 is asked for the investigation and improvement of mine-rescue and first-aid methods. This is an increase of \$51,300 over the amount appropriated for the current fiscal year. In addition, the budget approves the expenditure of \$40,000 for the purchase of an additional mine-rescue car.

The budget carries \$138,280 for fuel testing. This is \$2,280 more than was appropriated last year.

The budget recommends the expenditure of \$333,722 by the Geological Survey for its work falling under the technical heading of "geologic survey." This represents an increase of \$33,722.

The amount recommended for mineral resources reports is \$136,734. This is an increase of \$12,484. An increase of \$3,000 is allowed for the investigation of the mineral resources of Alaska, bringing the total for that purpose to \$78,000.

"THE ENGINEER'S SIDE OF THE COAL QUESTION" will be the subject of an address by Dr. George Otis Smith, Director of the U. S. Geological Survey, at Lehigh University Dec. 7. While in Bethlehem he will address the Thursday Evening Club of that city on "Independence in Coal."

Miners' Union Less Belligerent as Old Wage Agreement Nears End

Heavy Coal Stocks Above Ground and Idle Mines Believed to Presage Less Excessive Demands—Situation More Favorable to Consumer Than Preceding Last Strike

With the approach of the first of the year, attention in the coal industry is turning to the new wage agreement. While the United Mine Workers have had little to say as to what demands they will make, it is apparent that they are not particularly belligerent. With 76,000,000 tons of coal above ground; with 10,000,000 tons more at the head of the lakes than in any other year and with half the union mines down thus early in the winter, there is certain to be less insistence on increased operating expenditures. Such expenditures could do nothing more than close other mines and divert further business to the non-union fields.

BUSINESS CONDITIONS FAVORABLE

There is a tendency to compare the existing situation with that which preceded the last strike. There are some resemblances, but in the main the situation is importantly different. The inclination of the market is in the same direction, but it has not gone so far. The state of general business is much better. Between 10,000,000 and 11,000,000 tons of coal is being produced weekly, whereas production during the corresponding period preceding the last

strike was running some 3,000,000 tons lower. Relations between operators and mine workers are nothing like as strained as they were then. There is not the same tendency to cut wages in the non-union fields.

While the demands of the mine workers cannot be forecast, it is apparent that the differences which will arise at the forthcoming wage conference will not be of the same pronounced character as were those preceding the present agreement. The consensus of opinion is that there will be no strike and that the conferences will not be the occasion for any great amount of uncertainty among coal consumers.

Mine Fatalities Dwindle In October

Death Rate from Accidents Falls from 2.79 to 2.64 per Million Tons of Output

Accidents at coal mines throughout the United States during October, 1923, resulted in the death of 153 employees, according to a report by the U. S.

Bureau of Mines. With an output during the month of 57,895,000 tons the fatality rate was 2.64 per million tons mined, whereas in September it was 2.79, and in October last year it was 3.83. Of the 153 fatalities during the month, 129 occurred at bituminous mines indicating a rate of 2.62 per million tons, and 24 occurred at anthracite mines, in Pennsylvania, indicating a rate of 2.75. In October last year the bituminous rate was 3.90, and the anthracite rate was 3.48.

The total number of fatal accidents at all coal mines in 1923 to the end of October was 2,059, representing 3.79 fatalities per million tons, as compared with 1,443 fatalities in the corresponding period last year, representing a rate of 4.08. The bituminous rate for the same ten-month periods fell from 3.89 to 3.54, a reduction of 9 per cent, and the anthracite rate declined from 5.75 to 5.26.

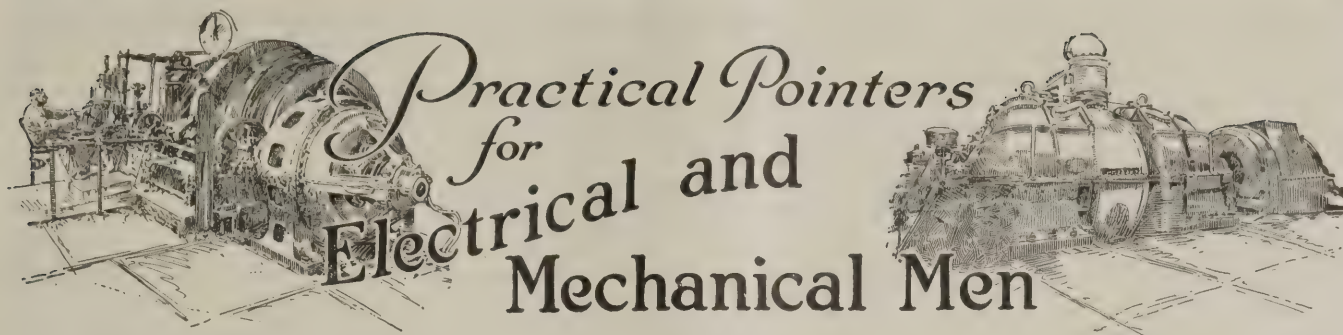

Comparing the record for the first ten months of 1923 with the corresponding period last year, the reports show a reduction in the frequency of deaths from falls of roof and coal, haulage, explosives, and electricity, and an increase in the number of deaths due to explosions of gas and coal dust, as indicated by the following rates per million tons of coal produced:

	1922	1923
Falls of roof and coal.....	2.015	1.776
Haulage.....	0.758	0.654
Gas and dust explosions.....	0.362	0.592
Explosives.....	0.190	0.160
Electricity.....	0.187	0.131

Coal Mine Fatalities During October, 1923, by Causes and States

Keep Belt Efficiencies High Lest Heavy Losses Result

Just a short time ago I was in a plant where a steam engine drove a main shaft by means of a belt, the shaft running through a wall and carrying power into an adjoining room. From that shaft a second line shaft was driven, and so on to the farthermost end of the room. I did not count the number of belt trains, but am sure there were at least eight and perhaps ten of them. In all my experience with belts I do not remember seeing as glaring an example of wasted power as I saw in this plant.

Assuming the efficiency of each unit drive to be 80 per cent and that the number of units or trains is 10, we must multiply 0.80 by itself ten times to get the efficiency of the complete system. In other words, the over-all efficiency of the drive from end to end is less than 11 per cent, which is surely too low an efficiency to sanction, these days.

One of the machines driven by the sixth train required about 20 hp. for its propulsion. After six trains it is easy to compute the efficiency of the transmission line to be about 25 per cent. The power generated by the engine to drive this machine was therefore 80 hp.

Now, if a rope drive had been installed from the engine direct to this machine it would have been possible to attain a much higher efficiency than 25 per cent. Let us assume then an efficiency of 80 per cent could be effected with a rope drive of this kind. The power required of the engine would

therefore be only 25 hp. In other words, the power saving would be 55 hp.

Another way to surmount this evil is to install group drives. Let the engine drive a generator and then distribute the current to motors scattered here and there over the plant. The efficiency of the generator should be at least 90 per cent and the motor the same. The over-all efficiency of the electric drive will, therefore, be very close to 80 per cent. From one of these motors one can therefore run a belt and get a high ratio of power to the driven machine.

Believing this subject to be important enough to warrant further elaboration I have developed a chart, which is shown herewith. By simply stretching a thread across the chart horizontally from left to right the reader is enabled to determine the over-all efficiency of any number of belt transmissions train, assuming an average efficiency for the units.

Above the chart is shown a train of ten belt units, beginning with a driven pulley. This is shown only to explain the chart more clearly. Above each column is a figure giving the number of units in the train up to and including that column.

For example, let us determine what are the efficiencies at the various points where the unit efficiency is 80 per cent. The dotted line drawn horizontally across the chart shows the answer at the points of intersection with the various columns. It will be noted that the columns at the extreme left and right

are both marked "1". They are identical, to insure an accurate horizontal line. Thus where the unit efficiency is 80 per cent, connect the 80 and the 80 in these two columns as shown.

At the end of the second unit it will be noted that the over-all efficiency is 64 per cent; at the end of the third unit, 51 per cent; at the end of the fourth unit, 41 per cent; at the end of the fifth unit 33 per cent, and so on. At the end of the entire train of ten units, the over-all efficiency is very close to 11 per cent.

This chart shows another interesting thing with regard to efficiency: The higher the efficiency in a unit the higher the over-all efficiency. Thus if 100 per cent efficiency were attainable there would be no loss from one end of the train to the other. With 98 per cent, which is attainable with carefully aligned shafting, properly treated belts, high-class bearings, proper lubrication, etc., it is possible to transmit 80 per cent of the initial power through the train of ten units. But where the unit efficiency is as low as 50 per cent the over-all efficiency is only one-tenth of one per cent. That is, if 1,000 hp. were delivered by the first pulley only 1 hp. would "get through."

Power leaks away at a surprising rate where efficiencies are low. If belt trains are necessary, and if much power is transmitted, make the efficiency of each unit as close to 100 per cent as possible.

W. F. SCHAPHORST,
Mechanical Engineer.

EFFICIENCIES OF BELT SYSTEMS

This chart shows the power transmission efficiency of any number of belt units. The example shows that if the efficiency of each unit is 80 per cent, the second belt delivers 64 per cent of the original power, the third belt 51 per cent, and so on. The tenth belt delivers only about 11 per cent of the initial power put into the system.

Calculating the Fan Drive and Horsepower on the Air

What is meant by the expression, horsepower produced on the air by a mine ventilating fan?

In fan drives there is first of all the horsepower of the driving machine, which usually is slightly greater than the horsepower delivered to the fan because the driver should not be overloaded and some reserve capacity always is desirable. Then again, there is the horsepower taken by the fan, which always is greater than the horsepower delivered by the fan. The horsepower on the air is the rate at which work is actually put on the air—that is, the power put into the fan minus the losses.

For example, what is the horsepower producing ventilation when the volume of air circulating is 60,000 cu.ft. per minute and the water gauge 3 in.?

The basic formula for horsepower is, 1 hp. equals 33,000 ft.-lb. per minute. Since 1 in. water gage is equivalent to 5.2 lb. per square inch, and 3-in. water gage is equivalent to 15.6 lb. per square inch, then the formula for the horsepower on the air is

$$\frac{60,000 \times 15.6}{33,000} = \text{roughly } 29 \text{ hp.}$$

Here the horsepower on the air is a little less than 29 and if we assume a fan efficiency of 70 per cent the horsepower to drive the fan will be about 42. The driver will therefore have to be capable of developing at least 42 hp. continuously.

Maintaining Trolley Wheels And Eliminating Troubles

Being a "trouble shooter" for an electrical contractor, I am naturally interested in the letter of Frank Parker, mine foreman at New Castle, Ala., which appeared in *Coal Age*, Nov. 8, stating his experiencing trouble with the trolley wheels used on his Baldwin-Westinghouse locomotive.

It has been my experience that the following troubles are the cause of practically all trolley-wheel sparking: low voltage caused by leaks to ground or too small wire; motors overloaded, bad return, bad contact—that is, the groove may be too wide for the size wire used or the tension of the wheel on the wire may be insufficient; the tension should be from 15 to 25 lb. measured at the wheel. This may be measured by hooking an ordinary spring balance to the harp and pulling downward.

The scale should be read just as the wheel leaves the wire. If in this case the harp does not line properly with the wire, it can be loosened and turned with a pipe wrench. Moisture, sleet or ice will cause sparking, of course. The last-named reasons are not to be considered for mine operation and Mr. Parker states that there is no moisture in the mine where he is experiencing trouble.

I would like to give a few points on the care of trolley wheels. They should be oiled about every 35 miles, which will save both spindle and bearing. There should not be too much side play and a wheel with badly worn spindle or bearing should be renewed. It is not economy to renew a wheel without renewing spindle or shaft, save in exceptional cases.

The stock of repair parts for trolleys should consist of wheels, shafts, cotter keys, bushings, harps and the proper washers, if required. The number depends on the character of service and the number of locomotives operated. It is general practice at the larger mines to keep a spare pole completely fitted with base and harp so that it can be readily substituted for a broken pole, thereby saving a delay.

GRADY H. EMERSON,
Electrician.

Electrical Repair & Service Co.
Birmingham, Ala.

Measuring Voltage and Current In Electrical Circuits

In the generation of electricity it is first of all necessary to produce a pressure called voltage. The unit by which we measure voltage is called the volt, and therefore the instrument by which we measure voltage is called a voltmeter. In measuring the voltage of an electrical system, it is necessary first of all to use a voltmeter designed to read voltages slightly above the voltage of the line. The method of determining the voltage of a line consists of placing the two voltmeter leads between

FIG. 1—MEASURING VOLTAGE

The voltmeter terminals are connected directly across the line to measure the line voltage or the potential difference between any two points on the circuit.

the two points where the potential difference, or voltage difference, is desired. Usually this will be between two metallic conductors, frequently being between two copper conductors. This need not always be the case, however, because in some conditions one conductor may be metallic and the other may be through the surface of the earth, commonly known as "ground." In street-railway work and in mine-haulage work the trolley wire is one conductor and the rail is the other conductor, and since the rail has direct contact with the earth we may also say that the trolley wire is one conductor and the earth is the other conductor.

In measuring voltage of a direct-current line, care should be taken to connect the voltmeter in such a way that the deflection of the needle will be in the proper direction. If this is not done, the needle will tend to turn in the opposite direction and may cause damage to the instrument. Direct-current voltmeters have what is called a polarity marking. This marking enables one to determine just which wire or conductor is positive or negative.

We have said that the unit of current is the ampere, therefore the name ammeter has been given to the instrument for measuring amperes. To measure the number of amperes, or rate of flow in a circuit, this instrument must be placed either directly into the circuit so that the current flows directly through the meter, or through a resistance element of known value. When

FIG. 2—AMMETER CONNECTION

To determine the amount of current flowing in the line the ammeter is inserted directly into the circuit so that the load current passes through the meter.

this second method is used the ammeter actually is a form of voltmeter and measures the voltage drop or voltage difference between the two ends of the resistance element. In this case the

FIG. 3—ANOTHER WAY TO MEASURE THE CURRENT FLOWING IN A LINE

Here the main current passes through a resistance element of known value and the ammeter actually measures the voltage drop across this resistance. The meter, however, is calibrated in amperes and reads direct.

meter is calibrated to read amperes because there is a definite relative between the voltage drop across the resistance and the current passing through it.

City of Vancouver to Go Into Coal Business

Determined to break the monopoly of the Vancouver Island coal producers, the city of Vancouver has decided to enter the coal business, selling to its citizens at cost plus cost of weighing and sacking.

Alderman R. P. Pettipiece, in control of the new department, states that he has an offer of 30,000 tons of coal from the Princeton-Nicola field for \$7.90 delivered or 40c. per ton more sacked. He says the Crow's Nest Pass Coal Co. offers to deliver coal at Vancouver for \$9.35 per ton. This coal has to travel more than 400 miles by rail, whereas the yards are selling Vancouver Island coal, from mines less than 60 miles distant by water, for \$12 per ton.

Problems In Underground Management

Fireboss Should Defend His Safety Rights, Receiving Company Aid

Shotfirer Discharged for Refusing to Fire Unsafely Charged Holes—
Miners Will Charge Shots for Others to Ignite Which
They Would Not Fire Themselves

BY W. H. LUXTON
Linton, Ind.

The right not to fire an unsafe shot is an equity of the shotfirer for which he should fight. I recall some years ago a man who was killed as a result of his recklessness in overcharging a hole. Following close on the heels of five or six other men he was hurrying out of the mine. The shot he had lighted proved to be a windy one, and the concussion of the air caught the man just as he was passing through a two-way door, and he was killed. Investigation showed that he had not properly mined his shot, which negligence cost him his life.

Not so long ago a shotfirer was discharged because he refused to fire several shots that could not be considered safe. Miners often drill and charge holes to be fired by a fireboss which they would hesitate to fire themselves. That shotfirer probably owes his life to his refusal to fire unlawful shots.

ASKED TO ACCEPT RISKS

Such is the urgent demand for coal that many firebosses hold their positions because of their willingness to take great risks. One man I know was told by a friend when firebossing in a gassy mine that he probably would be "let out" because he was too careful. Up to that time the records showed that no one had been burned by gas in that section of the mine. The fireboss finally left because the officials at the mine failed to co-operate fully with him in demanding safety.

Within a month or two thereafter, one poor fellow was blown into the sump and his buddy was injured by a car being blown upon him by a local explosion of gas in the place in which both men were working. Soon after that another explosion occurred in the same mine, causing much damage to the workings. Fortunately, no lives were lost.

If mine officials would share the burdens and responsibilities of their firebosses and shotfirers the work would not be unreasonably hazardous. The operator often may be well pleased to have the shotfirer fire all shots, safe or unsafe, and have the mine in shape

for full operation on the following day; likewise he may be pleased to get a good report on the condition of his mine from the fireboss, but after all he has to pay the compensation if an accident happens and he cannot afford to ask any man to take unnecessary risks or to be complacent as to conditions that may result in an accident.

Are There Any Dangers in Electrical Blasting?

A mine superintendent writes, saying: "Some have suggested changing the system of firing shots in use at our mine. What are the dangers of blasting coal with electricity, provided, of course, compliance is made with the mining law?"

The chief danger in the use of electricity for blasting coal in the mines lies in a faulty installation of the wiring system. The wiring of a mine should always be in charge of a competent mine electrician who is fully acquainted with mining conditions and requirements. Imperfect installation of the wires at any point may weaken the current below what is required for safe blasting.

BEWARE OF SHORT-CIRCUITS

Care should be taken that the wiring intended for locomotives, mining machines, pumps and signaling shall be so located with regard to the shotfiring system that by no possibility can the former energize the latter, even if either should fall on the other. The connection to the surface must be through two switches kept under lock and key, the key for one switch being held by the power-house engineer and the other by the shotfirer. Arrangements must be made that, except when the shots are to be fired, the circuits shall be so broken that no lightning discharge bridging the gaps on the switches can pass a current into the mine. At some mines it has been found that attempting to fire all the shots at once causes those that are delayed to explode into a dust-laden atmosphere.

Methods have been adopted to delay the shots in any series of rooms so that the first shot fired will be in the return current from the other unfired shots and the second in the return current from the others, and so on. Thus each shot will be fired in clear air.

ALL MEN MUST BE CHECKED OUT

There is always the danger that all the men may not be out of the mine when the shot is fired, and a result one or more may be killed. Care should be taken to place the shotfiring cabins where those throwing the switch will be out of danger. Persons also should be prevented from standing near the mine mouth when shots are being fired. Unfortunately, where a mine has a shotfiring system from the surface such as described, the miners are prone to think that as only property is menaced, and as that property is not theirs, they are at liberty to charge their holes at pleasure.

When a portable battery is used for firing, the strength of the battery must be sufficient to detonate the charge readily. Too weak a battery or the use of electric fuses of inferior strength may cause a misfire or start a deflagration in the charge, resulting in a hang-fire, which always is dangerous. The lead wires running to the shots should never be connected with the battery until all other connections are completed and due warning has been given to prevent anyone from approaching the zone of danger. The battery should be locked in a manner that will prevent anyone from meddling with it and the key should be in the possession of the man firing the shots.

Extinguished Carbide Light Nearly Ignites Gas

BY E. S. WADE

Superintendent, Windsor Power House
Coal Co., Warwood, W. Va.

Strange indeed was an accident described at the Panhandle Mining Institute of West Virginia. The fireboss made his round of the workings and found gas in the entry. In consequence he marked this working place as dangerous. On returning on his second round he went to this entry to make arrangements for the removal of the gas. When he got to this point he found the wireman standing near the danger board.

He told the fireboss that he had never seen gas act on the flame of a

safety lamp and that he was curious to see the cap it made.

As there was not much gas in the entry the fireboss consented to take him in with him, so he told him to blow out his carbide lamp. The fireboss started up the entry with his safety lamp, the wireman following close up behind with his extinguished carbide lamp in his hat. About half way up to the face of the entry the wireman stumbled on a lump of coal or a tie and fell forward.

The fireboss being right in front of him the wireman's carbide lamp scraped down the fireboss' right arm, turning the igniter and lighting the lamp. Fortunately the gas was near the roof and not low enough to be ignited. A severe explosion was avoided only by a hair, however, and the narration of the event may serve to warn others against the danger of taking even an unlighted carbide lamp which is generating acetylene gas into the presence of firedamp. It should be remembered that unburned acetylene gas adds combustibility to the atmosphere even if in only minor degree.

Use Suitable Gloves, Caps and Shoes to Avoid Accident

Co-operation between coal companies and mining inspectors is the keynote in the West. There the operators are trying to contrive with inspectors to get the best laws, however stringent, that will prevent accidents. In consequence the Rocky Mountain Coal Mining Institute is taking up the old question of safety and has had three reports from the members if its Safety Committee. That from P. F. Patterson, mine inspector of the State of Wyoming, and G. A. Knox, general superintendent, Gunn-Quealy Coal Co., gives special attention to gloves, caps and shoes. They say: "No habit is becoming more prevalent among miners and other mine workers than that of wearing gloves, principally flimsy canvas gloves, which afford no protection to the wearers and are the direct cause of many hand injuries. If gloves must be worn, and no doubt they will be, as the habit has become well established, they should be made from some heavy material and should fit the hands fairly snugly.

WOULD CHANGE MINER'S CAP

"With the many accidents to the head from falls of roof and coal, it would seem timely to suggest a change in the miner's cap. One made from fiber or light metal in the form of a helmet would seem preferable to those now being worn. Some such caps as these, we understand, are used to some extent in metal mines and their use in coal mines would no doubt cause a decrease in the frequency of certain accidents. It is a known fact that many fatal accidents have been caused by the fall of small pieces of rock that no doubt would not have proved fatal if the miner had been protected by some such headgear.

"Many accidents occur, too, from employees wearing shoes too light for their work, generally discarded dress shoes which afford no protection to the feet. The nature of mine work demands a shoe of heavy and rugged construction. The general wearing of such a shoe would no doubt cut down the number of accidents to the feet. A heavy hobnailed shoe, similar to the trench shoe worn by our troops in Europe, is in general use in the mines of Great Britain and Continental Europe. The shoes which mine workers wear in American mines are little better than moccasins and afford no protection to the feet and cause numerous accidents."

Robert Sneddon, of the Diamond Coal & Coke Co., Diamondville, Wyo., discussing this question, said that at Superior, Wyo., four years ago drivers and track laborers had many accidents from wearing shoes with hobnails in them. The nails destroy the hold the foot has on the car bumper and the men in consequence fall off the trip and are hurt.

It may be added that it is because of the greater danger of slipping when the foot is covered with a resistant sole that sailors go unshod. The hobnails further decrease the hold on any hard, especially a pitching, surface. Still, something may be said nevertheless for better protected feet.

Timber Bill May Be Reduced By Good Judgment

Before long we shall attempt economies in timber that hitherto we have not even considered. Even today the timber bill is one of the harassing problems of the coal producer and worthy of careful consideration. Because we have been wasteful for years is no reason why we should continue to be so, now that timber is becoming scarce.

All permanent timber should be treated with a preservative. Much valuable timber can be saved if the props and timber sets which are broken a short time after setting are reclaimed, the broken ends being used for propping thinner seams, being cut into cap-pieces, wedges or ties or being used for building cogs or chocks.

Hundreds of thousands of good timbers are lost every year in the mines through the carelessness of miners who let them lie in the waste until they are finally buried. A careful watch kept by officials in their daily rounds will do much to reduce the loss of good timber. The timber sent to a working place should be of the proper length, for the miner, if he finds the timber is too long or too short, is likely to throw it into the gob. Emphasis should be laid on the importance of drawing all timber in a systematic manner as the pillar retreats.

In pitching seams the recovery of timber is far more difficult and dangerous than in flat seams, for in such cases the rock from which the timbers are withdrawn is higher up the inclina-

tion than the men drawing it and whatever rock falls may slide down the slope and injure them. Nevertheless, many timbers can be recovered by selecting those posts here and there which have the least weight upon them. A small percentage of recovery of timber on pitching seams makes a marked reduction in costs as the handling of timber to the working faces is an expensive item.

In conclusion, it may be said that one of the best ways to conserve timbers is to establish some standard system of retreating. Thus less timber is used and whatever posts or crossbars are set for protection can be reclaimed before they become rotten, which is not usually done under the methods now general.

Are More Careful of Dust In Europe

John T. Ryan, speaking at the recent Salt Lake City meeting of the Rocky Mountain Coal Mining Institute, said that the regulations in Europe in regard to the handling of coal dust were better than ours. The British require that dust in the mines contain at least 50 per cent of incombustible matter and in Belgium and France not less than 70 per cent.

At the working faces, where rock dust would spoil the coal, water is used to keep down the coal dust. In France, where the mines are worked under concession and the operator shares his profits with the government, the mine inspectors have a word not only in safety but also in operating. The miners are required at these mines to sweep up the coal, and after that is done they water the working place.

In some places the crushing plants are underground and the material for crushing is derived from the workings themselves. The usual way of distributing the dust is to place it in boxes at intervals, possibly 1,000 or 1,500 ft. apart. Compressed air is turned on at night when few men are in the mine, and the dust is spread in a cloud over every exposed surface.

COLOR AN INDEX OF SAFETY

The degree of effectiveness of the dusting can be readily told by the color of the floor, as the dust is white. At some mines this dusting is done once in six months, in others once a year. Some use a car with a small fan operated by one of the axles of the wagon. The fan furnishes the air for blowing out the dust. In Yorkshire a new method of distribution is being tried. A 12-in. pipe is laid, and a fan forces rock dust through it. Ducts at intervals lead into the mine roadways. Properly installed it should be cheaper to operate than a water sprinkling system. In fact it is thought that it can be run for half the cost. In France dusting costs about half a cent per ton and in England about a cent. Rock dusting was essential in Europe, for the mines were too hot to make it advisable to moisten the air by the use of water or steam.

Discussion

How to Mine Seam of Pitching Coal with Heavy Parting

Slate Can Be Blown Down and So Disposed as to Permit Chutes to Be Laid from Coal Face to Top of Car

By J. W. POWELL

Contracting Engineer, Welch, W. Va.

An anthracite mining engineer asks in the issue of *Coal Age* of Nov. 15, p. 742, how timber may be recovered in a bed pitching at an angle of 25 deg. where chambers have been driven up in a 7-ft. seam overlaid by a rock parting 3 ft. thick and covered by a seam of coal, the thickness of which he does not state but which I assume is 4 or 5 ft. He says that the parting slate is blasted down on the retreat and that the top bench is brought back at the same time. It would seem that conditions are ideal for recovering any timber placed during the driving of the chamber.

My method of reclaiming the timber would be as follows: When the chamber has reached its ultimate length, a line of breaking holes should be drilled in the rock parting across the entire width of the chamber and back about 6 ft. from the face. This would enable the miner to get the proper angle for breaking the rock. Plenty of holes should be drilled in this round as the rock does not have a loose end. By thus shooting the rock adequately a clean cut will be insured clear across the face up to the top bench. This is an important requirement.

After all the holes are drilled, the props which stand under the section of parting rock covered by the range of shots should be pulled, which can be done quite readily by using any approved type of post puller. They will not have any great weight on them, being so close to the solid coal face. The total weight in any case will not be more than that of the 3 ft. of parting rock, for the top rock is stated to be solid and to form an excellent roof.

After this section of roof has been blasted another series of holes should be drilled in the parting roof so as to make the total length of roof broken down extend 20 ft. back of the face. All posts then can be pulled with safety, a post puller being used for that purpose, and any that are under too heavy a weight for such displacement can be blasted out by small plug shots set under the foot of the post. This latter it would be quite possible to do in a seam of this degree of inclination.

If the layer of roof above the lower bench was softer than the floor, however, the plug hole should be put above the post. This section of parting rock being blown down, the rock should be graded so that main and wing chutes can be laid to convey the coal in the

top bench to the car in the roadway as it is shot down. Then it will be possible to commence to retreat with the top bench. This top coal, as experience shows, will come down in large lumps as soon as a loose end is obtained and it can be loaded from the top of the fallen rock into the chute or car with little loss of coal. The rock in this way will not have to be removed and this will reduce the cost of obtaining the coal.

How to Save Timber and Time

By A SAFETY INSPECTOR

Welch, W. Va.

Blasting timbers with dynamite may be necessary at times and when the proper precautions are taken it is in some cases the safest method of removing them. It is done quickly and the time saved will often pay for the loss of timber. In general, however, the use of the post puller is much to be preferred, as thereby the post can be recovered in shape to be used again. The improvised battery ram in the form of a long timber swung on a rope is not a desirable way in which to remove timbers. In determining the way to remove a timber the cost of the method must be taken into consideration. That cost may easily exceed the price of new material.

Time costs are too frequently not given enough consideration. In many cases trackmen are required to pull and straighten spikes. It is doubtful economy when we consider the time required to make them fit for re-use.

We should never try to recover material until we are satisfied that it will pay to do so, taking into account the depreciation of the used material. Some companies lose money by abandoning good equipment and supplies. On the other hand, money often is lost in the attempt to recover material, which is then frequently used at a disadvantage because of its poor condition.

Other losses in company work occur when drawing back pillars. Sections of track frequently are taken up and deposited in a place where they will soon have to be moved again. They should be put where they will be out of the way until needed in another place. It may happen that material thrown aside in the manner mentioned will be covered up by a fall and lost beyond recovery.

One often sees places driven where the waste is thrown against the pillar only to be moved again when the rib is drawn back. These and other items occurring in the daily operation of mines may seem mere details, but in most cases they represent the difference between profit and loss.

Should Fireboss Be Examined At the Working Face?

In view of the frequency with which firebosses fail to detect firedamp it is permissible to call attention to the last paragraph of Art. 24, Sec. 4, of the Bituminous Mining Law of Pennsylvania which reads:

"Certificates of qualification of firebosses shall be granted to persons who have given to the Board of Examiners satisfactory evidence of their ability to perform the duties of firebosses in gaseous mines, and who shall have received an average of at least 65 per cent in the examination, and shall also have undergone an oral examination in the presence of explosive gas."

I am informed by candidates who passed the last examination and have received certificates issued by the Board of Examiners, making them eligible for appointment to the position of firebosses in the bituminous mines of this state, that they were not submitted as the law requires to an "oral examination in the presence of explosive gas."

I question whether the papers of these men are valid, for they were not examined in strict conformity with the requirements of the law. This I believe is necessary to render their appointment lawful.

Our old firebosses, who are all certified men, tell me that they were required to demonstrate their ability to detect gas by a practical test in the mine. Naturally, I cannot blame them for questioning the right of these men to appointment—*Superintendent*.

Rapid vs. Correct Way of Calculating Arc

To settle a dispute regarding the correct method of calculating the length of a circular arc, kindly explain the right way of making such a calculation. I want to find the length of an arc of 30 deg. on a circle whose radius is 14 ft. I have been solving this problem as follows: The full circumference of the circle is $2 \times 3.1416 \times 14 = 87.96$ ft. Then, dividing this by the 360 deg. forming its circumference gives for the length of an arc of 1 deg., $87.96 \div 360 = 0.244$ ft. Finally, multiplying this by 30 gives for the length of an arc of 30 deg., $30 \times 0.244 = 7.32$ ft.

Others claim that to solve this problem correctly I should multiply the sine of 1 deg. by 14 and that product by 30, which gives $14 \times 0.01745 \times 30 = 7.329$ ft.

Cambria, Ill.

STUDENT.

Either method gives a result which is reasonably correct though the second method is based on an approximation, for the sine of 1 deg. is not the same as the length of the arc subtended by an angle of 1 deg. Calculated to more places of decimals the results would be more nearly equal than you have shown and the latter method is perhaps a little the more rapid.

Production and the Market

Weekly Review

Recent advances in general industrial activity have not been reflected in the demand for bituminous coal. Inquiries have increased, there is some interest in contracts covering the first three months of 1924 and contract shipments are being increased here and there, but spot sales are on a day-to-day basis. Distress coal can be picked up at bargain prices in every market. The National Association of Purchasing Agents has advised its members to hold to present stocks, to buy for current needs while prices are low, coal plentiful and transportation favorable, and to avoid a general rush into the market.

Production of soft coal as well as prices continue to lose ground. Production during the week ended Nov. 24 was around 10,170,000 net tons, an increase of 454,000 tons over the previous, a holiday, week, but a decrease of 555,000 tons compared with the week of Nov. 10. Average prices reached the lowest level for any week of this year, *Coal Age* Index showing 181 as of Dec. 3, a drop of five points from the previous week. The average price was \$2.19. Declines registered in Pocahontas, southeastern and western Kentucky, Clearfield, Cambria, Somerset and Kanawha coals were but partly offset by increases in southern Illinois, Springfield, Clinton and Pittsburgh districts. Lump-coal prices suffered the most with mine-run firm in most fields and screenings erratic.

EXPORT MARKET SHOWS SIGNS OF REVIVAL

Activity in the export market has revived somewhat. Competition between British and American coal is keen, as is shown by one piece of business last week. A New York house sold a cargo of Kanawha coal to the Bordeaux Gas Works under \$5 c.i.f. Inquiries have been received for between 30,000 and 40,000 tons of gas coal for Stockholm, deliveries to extend over next year.

Reduced production in Illinois and Indiana has sent

prices for screenings up and the closing of some consumer-owned mines has put the owners on the market for heavy tonnages of steam coal. Working time in the Middle West is decreasing gradually. Little activity is noted in the St. Louis market, except in the cheaper grades of coal handled by retail dealers. The demand for Kentucky coal is going from bad to worse. A better movement is reported out of Duluth, but at Mil-

	Week Ended Nov. 26	Season to Nov. 26

waukee the docks are not busy. Trade in Ohio continues dull notwithstanding a readjustment in the circular on smokeless coals. Consumers in New England continue to lack interest. At New York more inquiries were received, including some regarding contracts for the first three months of the new year, but nothing definite regarding prices has been decided.

Anthracite production reached 2,100,000 net tons during the week ended Nov. 24, only 65,000 tons below the high record for the year. It is estimated, however, that production for last week did not exceed 1,800,000 tons, owing to the holiday. More hard coal is being

delivered to retail dealers in the East now that the Lake shipments are nearly at an end, and as a result of the easier condition of the market some cancellations of the high-priced coal have been reported.

Midwest Steam Prices Stiffen

The remarkably low point of production in Illinois and Indiana has at last begun to have a real strengthening effect on the price of screenings. Good southern Illinois screenings, which have been running at \$1.40@1.50, have climbed about 15c., although there is no great volume moving at that price because of short-term contracts now being cleaned up at the lower figure. Central Illinois screenings have improved, mainly because the Standard Oil Co., having shut down its Illinois mines, contracted for about all the available Springfield district supply of fine coal at \$1.25 until April 1. The previous price had been around 70c. Indiana Fourth Vein steam sizes also ascended from an average of \$1.35 to \$1.60, and Fifth Vein from \$1 to \$1.25.

The situation in domestic sizes is discouraging. "No bills" in all the larger sizes are accumulating in all fields with no

good prospect ahead of moving them in a hurry. This, coal experts contend, is bound to push steam sizes higher. This development is especially desired by two or three operators who have small quantities of screenings on the ground in scattered parts of Illinois, and by most of the many operators who are trying to fill their low-price contracts as quickly as possible so as to have coal ready for a high-level steam market along toward the end of this month.

Kentucky and Eastern coal has been cutting heavily into the domestic market all through the Middle West and Northwest at prices low enough to give them the edge on trading in spite of their higher freight rates. Shutdowns in some of those competing regions, however, are expected soon to reduce the volume of this coal, so that the price will ascend to a point that will reduce their competitive power. Good eastern Kentucky lump is selling at \$3@3.25 and western Kentucky at \$2.75, and their producers are hungry for markets now that Lake trade is dying. A flood of cheap smokeless mine-run, selling through the Chicago market at \$1.75@2.25, helps materially to keep the domestic market in Illinois and Michigan flat.

Midwest fields, of course, continue to run on flat tires all

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

	1923			1922
	Dec. 3	Nov. 26	Nov. 19	Dec. 4
Index	181	186	183	326
Weighted average price	\$2.19	\$2.25	\$2.21	\$3.95

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on 'Prices of Coal and Coke, 1913, 1918,' published by the Geological Survey and the War Industries Board.

around. Working time decreases little by little and there is nothing in December to hope for except a continuous run of blizzard weather. Otherwise nothing much is expected of the market until Jan. 1. Railroad tonnage in most fields is light.

St. Louis Trade Is Quiet

Mild weather continues at St. Louis with a change of about 10 deg. in temperature. This has brought a little activity in retail trade in cheaper grades of coal. Country domestic is quiet and there is no call for country steam. Local wagonload steam shows a little improvement, but carload is at a standstill. Dealers report nothing doing in anthracite, smokeless or coke. With all yards loaded they are waiting for cold weather.

Kentucky Slumps Lower

From bad to worse appears to be the situation in Kentucky so far as demand is concerned. Reduction of general demand for prepared sizes is resulting in still fewer operating mines in west Kentucky, and this is making for slower production of screenings and a better price. Western Kentucky screenings have advanced to 70@75c. for pea and slack and 90c.@\$1.10 for nut and slack, while prepared sizes have remained practically unchanged. Screenings have been

sold down as low as 40c. within the past few weeks. However, mine run is selling at \$1.50@\$1.90 and a top of about \$2, but is moving very slowly due to the oversupplied condition of the screenings market.

Jobbers are generally complaining over lack of demand for coal in quantity in any size, while operators bemoan time lost through lack of sales. The western field doesn't figure more than about 33½ per cent of capacity at this time, and the eastern no better than 50 per cent. The larger mines in some instances are producing a fair tonnage, but companies with several mines are making no effort to operate all their plants.

Northwest Is Full of Fuel

The movement of coal to Duluth took a new lease on life last week, when forty-eight cargoes arrived, of which five were anthracite. Twenty-six are reported on the way, in which are included four of hard coal, and it seems that at least twice that number of anthracite arrivals will be scored before the week is through.

Receipts of soft coal are large. In the event of a strike next spring there will be ample stocks on docks. Should the strike not materialize, there will undoubtedly be some hurried unloading. The industrial demand for soft coal is good but the commercial demand is flat. Public utilities, however, are suffering from lack of water power, and are forced to turn to coal.

The Milwaukee market remains quiet, but the weather is hardening slowly, and dealers are looking for real business soon. The market is glutted with all-rail Pocahontas, and mine run is down 50c. to \$8 for steam and \$9.50 for domestic use. Jobbers report the soft-coal market in general as dumpy, but as yet no shading in price other than in Pocahontas has developed. Cargoes continue to arrive by lake. The docks are full and some of the shipments will be held afloat. The total coal received at the port from all sources during the year promises to break all records.

Minneapolis, center of the war for Northwest markets between rail and Lake shippers, observes the docks stocking heavily preparatory to a strike or to a rate decrease sufficient to let them flood the country with Eastern coal. Hocking and Youghiogheny lump are now \$6 and \$6.50 with pile-run 75c. less on Hocking and 50c. less on Youghiogheny. Illinois and Kentucky shippers strive to maintain their circulars, but cannot in the face of the bitter competition between the various factions.

Western Trade Drones Along

Conditions are little changed throughout the Southwest and West in coal trading, in spite of snowstorms in Colorado, Nebraska and Kansas. These served to stimulate buying a little, both in Southwestern district coal and in fuel from Colorado. However, Kansas mines have not worked better than 60 per cent and there have been no changes in price. Nevertheless the ratio between working time and demand is such that "no bills" at least have not increased.

In Utah winter weather has created some retail business but the demand is easily supplied from small stocks on hand and buying has not been greatly increased. Low production of domestic sizes is pushing the price of slack up.

Price Readjustments in Ohio

Readjustment in the smokeless coal market continues at Cincinnati. Reduced prices for lump and mine-run were shown on the December circular, but New River operators and some brokers undersold these prices. Many of the mines in the Hazard, Harlan, Elkhorn, Big Sandy and southern West Virginia regions which closed early last week on account of the holiday remained closed the balance of the week. A surplus of coal together with unseasonable weather and light demand caused no change in the market. Retail prices receded with mine prices.

Scarcity of slack in the Cleveland market caused an advance in price, due in most part to the cut in production. Otherwise the market is dull and consumers are showing practically no interest. With lake shipments practically ended for this season receipts of bituminous coal at Cleveland increased, resulting in a surplus of coal. Notwith-

standing the present dullness, the trade is optimistic and expects heavier buying with the new year.

A slight increase in the demand for domestic coal was noticed at Columbus, due to colder weather, but it was easily met by the retail dealers, who are heavily stocked, as well as by consumers, who generally have their house bins filled. Pocahontas and splints are in good demand. The dullness extends to the steam-trade demand. Railroad demand is steady, while purchasing agents of large consumers and manufacturers are buying distress coal at low prices. Screenings are in slightly better demand. Many mines are closed and are not expected to reopen until demand is better.

The Pittsburgh coal market continues to show a better tone all around as compared with conditions a few weeks back, but last week there was no further improvement in prices, except in slack. A feature of the market is its failure to yield any on account of the ending of the lake season, when it is normal for prices to go off somewhat for December. Low prices had been reached some time ago, and operators seem to have made such careful provision against being caught with the necessity of selling any additional coal that, if anything, the market stiffened somewhat. Slack is expected to go up to the neighborhood of mine-run price. Steam slack is being quoted at \$1.25@\$.1.30, with gas slack at \$1.25@\$.1.35.

New England's Spurt Over

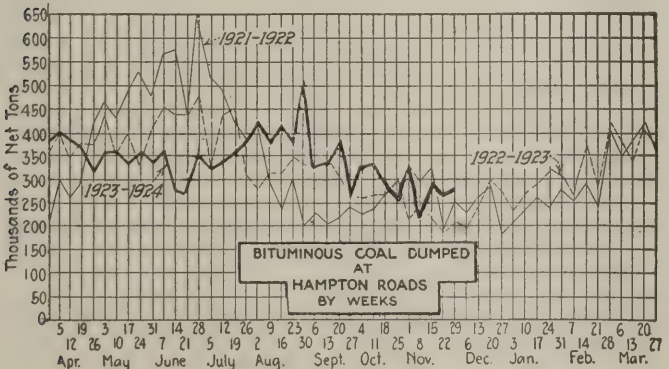

In New England the faint spurt of a week ago has about worn off. Labor troubles on the Virginian Ry. did not prove the hardening factor that shippers hoped, and \$4.75 per gross ton f.o.b. Hampton Roads was the highest price quoted on No. 1 Navy Standard coals. A few sales have been made at \$4.50, and it is probable that these will be duplicated soon unless something unforeseen occurs. Consumers show no greater interest in the spot market than at any time during the past sixty days, and at least one of the smokeless agencies announced a 25c. lower price on month-to-month contracts than during November.

While distributors are asking \$6 per gross ton on cars it is conceded that what few buyers there are can still cover at \$5.25@\$.5.50. There has been nothing to improve inquiry for spot coal and the requirements of those who chose during November to buy at current prices for use early next spring have not been satisfied. There is no perceptible change in all-rail coal from central Pennsylvania. Only the output of non-union sections has any apparent opening even in the more western part of this territory, and quotations are freely made on fair grades roughly classified as Pool 10 at \$1.50@\$.1.60 per net ton, f.o.b. mines.

There is a small volume of bituminous moving from Philadelphia and from New York, but practically all of this is on contract commitments and tends to diminish from week to week.

Consumers Ask About Contracts

A better feeling exists in the New York market for soft coal. Inquiries have increased and some consumers are asking about contracts from January to April next year, and others to cover the entire twelve months. The lack of distress coal was reflected in the opening of bids by the U. S. Shipping Board at New York for 2,300 gross tons of either Pool 9 or Pool 71 coal, the prices ranging from \$4.80

to \$5.69 alongside, a substantial increase over previous offerings. While houses as a rule were not willing to quote prices on contracts for the first three months of next year the opinion was they would range as high as \$3 for Pools 9 and 10. Consumers in Philadelphia are not willing to buy large tonnages, although producers try to impress upon them that the present prices are the lowest possible. Although movement remains in fair volume, shippers say business is as dull as at any time in the past four or five months. It is expected that iron plants will enter the market before the first of the year. Curtailed production following the close of lake shipments has tightened the supply of slack.

Demand at Baltimore for gas and steam coals is running below normal. Lack of demand has affected the smokeless coal market in West Virginia, as well as prices. Wage readjustments in some instances have permitted a resumption of operations in the Upper Potomac and Georges Creek regions. At Birmingham there is considerable dullness and conditions are unsatisfactory. Spot coal is in light demand and mines without contracts are finding it difficult to maintain a short working schedule. The bunkering trade is hard hit by oil competition.

Cancellations for Anthracite Received

Stove and chestnut sizes of hard coal are becoming more plentiful in the East, due to the practical stopping of Lake shipments, causing producers to distribute their coal in other directions. Egg and pea coals together with the steam sizes are available to all buyers. Some cancellations of orders for high-priced coal have been received by wholesale dealers, but so far they have not been in large volume. Like New York, Philadelphia has received better shipments of all sizes, and while they have not been large the demand for chestnut coal is easier. In the absence of cold weather there is no rush for coal. The immediate demand of consumers of hard coal at Baltimore is being taken care of by the increased arrivals. There is a heavy demand for anthracite in Toronto, but with arrivals fairly regular, dealers believe they will be able to supply all requirements. Shipments of hard coal to New England and eastern New York by rail during the week ended Nov. 24, the American Railway Association reports, were 3,646 cars, as compared with 3,455 cars the previous week. During the week ended Nov. 25, according to the Geological Survey reports, 171,975 net tons of hard coal were shipped from Lake Erie ports, making the shipments for the season to date 3,368,287 tons.

Production of beehive coke showed an increase of 6,000 net tons during the week ended Nov. 24 when compared with the previous week, the Geological Survey reports showing an estimated production of 260,000 tons, as compared with 254,000 tons during the week ended Nov. 17. The cumulative production during 1923 to Nov. 24 stood at 16,695,000 net tons.

Foreign Market And Export News

Welsh Coal Market Shows Improvement; October Exports Increase

Production of coal in Great Britain gained 2,000 tons during the week ended Nov. 17, a cable to *Coal Age* stating that 5,574,000 tons were produced. The previous week's output was 5,572,000 tons.

There has been an improvement in the Welsh market. After a series of delays, tonnage is moving more freely. Shipments are increasing and mine suspensions are less frequent. The tonnage position, however, is not satisfactory owing to the diversion of steamers to the Far East, and also to the Black Sea.

Exporters who sold on c.i.f. terms based upon the freights ruling some weeks ago are in some cases faced with losses instead of profits. Some mines are fairly busy, while others continue to have heavy stocks of coal on hand, and find it necessary to make concessions to buyers to get quick movement. On the whole, the operators are well booked until the middle of January and with the approach of Christmas anticipate growing pressure.

Contract business for 1924 is under negotiation though some consumers on the Continent are inclined to buy on the open market rather than place new contracts at prices above those now in force.

The Newcastle market remains steady but quiet. Most of the mines have sold their output for the rest of the year. There is some easiness for prompt shipment, partly owing to bad weather and delayed arrivals of shipping, but mainly as a result of the difficulty which German buyers are finding in obtaining credits for coal due to be shipped.

French Coal Imports and Exports

There were produced by the French mines, excluding Sarre, during September 3,321,297 metric tons of coal and lignite; 181,648 tons of coke, the independent mines not included; and 264,787 tons of briquets, as compared with 3,405,028 tons of coal and lignite; 180,860 tons of coke, and 263,164 tons of briquets in August. During the same period France imported 2,619,831

tons of coal and lignite, 280,316 tons of coke and 46,374 tons of briquets, while the importations in August were 2,241,157 tons of coal and lignite 274,606 tons of coke and 64,460 tons of briquets.

Exports in September were 156,137 tons of coal, as compared with 187,725 tons in August; 50,944 tons of coke as against 59,976 tons, and 19,536 tons of briquets as compared with 12,545 tons.

Hampton Roads Prices Stronger

Market conditions at Hampton Roads last week continued dull, except that prices showed a little more strength. Despite the strike on the Virginian Ry. a fair volume of coal continued to arrive at Sewall's Point.

Coastwise business was fair with bunkers holding their own. Foreign movement was slow, while the prospects were not bright.

The tone of the market was generally dull, and business was at a lower ebb than is usual at this time of the year. Domestic trade was promising and the prospects for an increase in coastwise movement during December was bright.

Coal and Coke Exports and Imports

During October 400,599 gross tons of anthracite and 1,488,887 tons of bituminous coal were exported from the United States, as compared with 404,999 tons of anthracite and 1,729,425 tons of bituminous coal in the corresponding month of last year. Of the total Canada received 1,247,952 tons, Italy 59,068 tons, France 27,045 tons and Cuba 52,680 tons. There was 77,737 tons of coke exported as compared with 38,613 tons in October of last year.

During the same month the United States imported 40,213 tons of anthracite and 89,059 tons of bituminous coal of which 57,026 tons was dutiable. During the corresponding month of last year there was imported 105,501 tons of anthracite and 1,143,157 tons of bituminous coal. Of the imports last October the United Kingdom furnished 10,277 tons, Canada 57,026 tons, and

Australia 15,334 tons. Imports of coke amounted to 3,815 tons, as compared with 22,880 tons in October of last year.

French Coal Prices Advance

After a strike which continued a few days the workers in the French coal mines were granted increases ranging from 1 fr. to 3 fr. in all Basins, and up to 5 fr. in Lorraine. It is expected that due to the advances in wages the selling prices of coal will advance from 3 fr. to 5 fr. per ton.

Deliveries of coal from the various mining fields are satisfactory, and British exports are normal. Due to decreased activity at the plants demand for industrial coals is slower. Announcement was made that contracts aggregating about 200,000 tons of coal have been placed with American houses.

Advises That I. C. C. Modify Report on Car Distribution

In a tentative opinion by Examiner David T. Copenhafer in the case of the Northern West Virginia Coal Operators' Association versus the Director General of Railroads, the examiner finds that the Interstate Commerce Commission should modify its previous report. The practices of the Director General during 1919 and 1920 in the distribution of coal cars as between mines on the Monongahela and Morgantown & Wheeling railways and the mines on the Pittsburgh & Lake Erie, south of Pittsburgh, and on the Monongahela Division, southwest branch, and the Pittsburgh West End Division of the Pennsylvania R.R., says the examiner, subjected operators of coal mines on the first two named roads to undue prejudice and disadvantage to the extent that the percentage of cars furnished the mines on the latter roads in each instance was less than the percentage of cars the mines as a whole on all lines under consideration would have received had all the system cars placed for coal loading on those lines been distributed equally.

In its original report there was no basis for findings as to the extent of damages. For that reason the case was held open for further hearing. It has developed that the figures upon which the commission's findings were based included numerous privately owned cars, which should not have been included in the distribution.

"The complainant's mines," says the tentative opinion, "were entitled only to such car supply as they would have received had the available cars been distributed equally. With an equal distribution, the mines on all lines here considered would have received 87 per cent and 58.7 per cent respectively, of their orders during the periods July, 1919, to October, 1919, and December, 1919, to February, 1920, inclusive, or 74.3 per cent for the entire period."

Ruling Issued on Indiana Rates

In the complaint of the Indiana State Chamber of Commerce against the Baltimore & Ohio and fifty-three other railroads the Interstate Commerce Commission made a ruling in a decision dated Oct. 31 in which it orders the defendants according as they participate in the transportation "to establish, on or before Feb. 18, 1924, upon notice to this commission and to the general public by not less than 30 days' filing and posting in the manner prescribed in section 6 to the Interstate Commerce Act, and thereafter to maintain and apply to the transportation of coal, in carloads, from mines in the State of Ohio and the Inner Crescent district of Pennsylvania, Maryland, West Virginia, Tennessee, Virginia and Kentucky to points in the Muncie group,

rates which shall not exceed those contemporaneously in effect to Fort Wayne, Ind.; to points in the Peru group, rates which shall not exceed those contemporaneously in effect to Fort Wayne and Muncie and points taking the same rates by more than 5c. per net ton; and to points in the Elkhart group rates which shall not exceed those contemporaneously in effect to the Fort Wayne group by not more than 20c. per net ton."

Indiana industries, coal operators and miners, through representatives in the Indiana State Chamber of Commerce, the Indiana Bituminous Coal Operators' Association and district 11, United Mine Workers, recently argued before the Indiana Public Service Commission that Indiana intrastate coal freight rates on hauls exceeding 30 miles are too high and that the commission's tentative order does not reduce them enough. Railroads hold that the Indiana rates are not out of line.

Record Coal Shipments to Lakes

Up to Nov. 27, according to reports filed with the car service division of the American Railway Association, 30,618,000 tons of coal have been dumped at Lake Erie ports for shipment since Jan. 1 this year, of which 29,036,000 tons were cargo coal and 582,000 tons bunker fuel. This is a larger tonnage than has ever been dumped previously.

By the time the navigation season closes it is estimated that a total of 31,313,000 tons will have been dumped, of which 29,700,000 will be cargo coal and 1,613,000 tons bunker coal. The best previous record was made in 1918, when 29,388,242 tons of both cargo and bunker coal was transported by the railroads and dumped at Lake Erie ports during the entire season.

May Acquire Scotts Run Ry.

The Monongahela Railway Co. is making arrangements to take over the Scotts Run Ry., formerly the Morgantown & Wheeling. Permission has been sought from the Interstate Commerce Commission to make such financial arrangement as the issue of one million dollars in common stock of the Scott's Run Company, which the Monongahela will buy at par. It is understood the new management will make improvements necessary to enlarge the coal-carrying capacity of this road.

Plan New Road in Indiana County

Extensive coal deposits in Indiana County, Pennsylvania, would be opened for development if a new railroad, to be known as the "Conemaugh & Blacklick," is built. Application for a certificate of public convenience has been filed. The proposed line would connect the New York Central at Nant-y-Glo of Heilwood with Johnstown.

Challenges Central Rates in Ohio

Rates of the New York Central Lines on coal shipped from mines on the T. & O. C. division of that system to the Fairfield Paper Co., at Baltimore, Ohio, have been challenged in a complaint filed with the Ohio Utilities Commission.

Association Activities

The Board of Directors and Executive Committee of the **National Retail Coal Merchant's Association** will meet at Hotel Shoreham, Washington, D. C., Friday and Saturday, Dec. 14 and 15.

The **Smokeless Coal Operators' Association of West Virginia** will hold its annual meeting at Washington Hotel, Washington, D. C., on Dec. 13. The principal business will be the election of a Board of Directors to be followed by the election of officers. The meeting will be followed by a luncheon at which United States Senator David A. Reed, of Pennsylvania, will make an address.

The **Wholesale Coal Club** is the newest coal organization in Indianapolis, composed, as the name would signify, of the leading wholesalers of the city. The organization meets once a month, the principal purpose being to get better acquainted, according to Arch V. Grossman, president. H. B. Glover, with the Knox County Consolidated, is the vice-chairman, and Ray Mulvihill, secretary of the Cedar Creek Coal Co., is the secretary.

About 500,000 copies of a digest of the report of the U. S. Coal Commission on retailing coal will be distributed by the **National Retail Coal Merchants Association** as part of a campaign planned by the association to inform the consuming public regarding the fuel situation. At the same time the association will undertake a campaign to enlarge its membership. Officials of the association are highly pleased with the report of the Coal Commission on the retailers. In the words of Joseph E. O'Toole, resident vice-president, "The Coal Commission gave the retailers a clean bill of health, and we want the public to know of it."

Coming Meetings

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

Tug River Coal Operators' Association. Annual meeting Jan. 4, 1924, Bluefield, W. Va. Secretary, C. C. Morfit, Welch, W. Va.

New England Wholesale Coal Association. Annual meeting Jan. 8, 1924, Boston, Mass. Secretary, R. S. Townsend, Boston, Mass.

Engineers' Society of Western Pennsylvania. Annual meeting Jan. 15, 1924, Blue Room, William Penn Hotel, Pittsburgh, Pa. Secretary, K. F. Treschow, Pittsburgh, Pa.

American Wood Preservers' Association. Annual meeting Jan. 15-17, 1924, Hotel Buehlebach, Kansas City, Mo. Secretary, P. R. Hicks, Chicago, Ill.

Northeast Kentucky Coal Association. Annual meeting Jan. 24, 1924, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

Obituary

T. L. Sharpe, aged 69 years, died in Montgomery, Ala., Nov. 21, Mr. Sharpe, together with Wm. Cook, Sr. operated the Black Creek Coal Co., at Nauvoo, Walker County, Ala., and also was interested in mining operations in Kentucky. He had been long identified with mining operations in the Alabama field and was widely known. Interment took place at Demopolis, Ala., his birthplace.

News Items From Field and Trade

ALABAMA

The Paramount Coal Co. is making two openings near Helena, Shelby County, where the company now has one mine in operation. The openings are on property comprising about 250 acres leased from the Tennessee Coal, Iron & Railroad Co. T. S. Abernathy is president and J. M. Donaldson, vice-president and general manager of the Paramount company.

General Wm. L. Sibert, well-known army officer and native Alabaman, has been appointed president of the State docks commission, vice Gordon Crawford, resigned. General Sibert will supervise the building of docks and terminals at Mobile, to which work the state will lend its aid to the extent of \$10,000,000. The salary of General Sibert has been fixed at \$10,000 per year.

COLORADO

A large natural gas gusher was struck near Fort Collins, in the center of the northern Colorado lignite fields recently. This well is one of the largest of its kind in that section, producing approximately 82,000,000 cu.ft. of natural gas per day. It is expected that the Colorado Public Service Company will take this well over and pipe this gas into Denver and surrounding vicinity.

The Boulder Coal Mining Co. has been incorporated in Boulder, Colo., with a capital of \$100,000, by H. Bennett, T. Tison, J. Bertotti, H. H. Parker and R. Moschetti.

CONNECTICUT

In a report sent to Governor Templeton, by the Hartford Chamber of Commerce, Governor Pinchot, of Pennsylvania, is held in part to be responsible for the high price of anthracite. The blame, according to the report, is shared also by the middlemen and operators. The findings are the result of a survey made by the chamber upon request of the Governor. The report says there is nothing that Connecticut, through its Legislature or Governor, can do to alter conditions. The remedy, it says, lies primarily with Pennsylvania, which has a monopoly of the anthracite supply of the country.

ILLINOIS

The recent closing of the two mines near Carlinville, of the Standard Oil Co. presents an interesting phase of coal operation. These mines are models of economy. They worked regularly and yet other mines sold the Standard Oil Co. coal for their refineries below the cost of their own. The only reason for this is that "the rest of the tonnage" which goes to the public is expected to carry the loss sustained on the tonnage shipped to the Standard Oil Co. The Standard mines are down indefinitely.

The Cripple Creek Coal Co. of Galesburg, has leased 1,200 acres of land east of that city and a new shaft will be sunk in the spring.

Due to its ability to buy coal cheaper than it can be produced the Standard Coal Co. has closed two of its mines, one located at Schoper and the other at Berry, throwing approximately 1,000 men out of employment. Officials of the company have declared for some time that coal could be purchased cheaper in the market than it can be mined.

The Wabash R.R. and the Consolidated Coal Co. of St. Louis are still acquiring coal rights to the north, east and south of Taylorville. In the last two weeks of November they added one thousand acres to their holdings. The two now have their coal rights in solid bodies and it is expected that they will both begin mining coal within the next season. The Wabash has 30,000 acres and the Consolidated 20,000, involving a total expenditure of more than \$1,000,000.

The Bissell Coal Co. has changed its name to the Utilities Coal Corporation, Inc., with offices at 810 Ferguson Building, Springfield.

The Burlington Ry. has announced plans for the new freight yards at Willows to cost \$700,000. These yards will have a capacity of 1,000 cars and will be used to facilitate coal shipments. Ninety acres will be taken over for the yards.

Fire on Dec. 1 destroyed the old tippie and coal washer of the Taylor Coal Co. at Herrin.

INDIANA

A stockholders' report of an Indiana coal mine proves that not all coal mines are fizzes even in these trying times. This mine has a capital of \$300,000. The earnings from Nov. 1, 1922, to Oct. 30, 1923, were \$240,000. This mine does not sell its own coal. It is handled through jobbers.

Among the reasons why Indiana mines are 40 per cent shut down and why the other 60 per cent work only half the time, William Mitch, secretary of District II of the United Mine Workers, recently said publicly "there appear to be too many mines and too many miners." John Hessler, district president, said a freight-rate adjustment to give Indiana coal a better chance in competitive markets would help.

Regulations of the State Board of Mines and Mining governing enforcement of mining laws in wagon mines are discussed in an opinion submitted to Cairy Littlejohn, state mine inspector, by Attorney General U. S. Lesh. Under the law, mines employing more than ten men are subject to certain regulations of the board. Mr. Lesh said the fact that fewer than ten men are employed in a mine during part of a year would not protect the owner from prosecution for any violations occurring at the time when the number of employees exceeded ten.

Among the mines which have recently joined the popular custom of closing down are Big Creek Coals, Inc., No. 6, at Grayson; Franco No. 2, at Fautlon, and the mine of the Orchard Coal Co., at Marion. The shutdowns are the result of lack of orders and indefinite in length.

KENTUCKY

A total of \$1,050,000 has been allotted by the War Department for use in continuing the river channel development work in the Louisville district of the Ohio River, and an additional \$950,000 for the Cincinnati district, mostly for lock and dam work.

Barbourville interests have leased a mine at Anchor belonging to the Consolidation Coal Co.

MASSACHUSETTS

Fuel Administrator Hultman in a recent statement says that seventy communities in Massachusetts have received less than 25 per cent of their normal hard-coal requirements to date and calls on shippers to end an apparent discrimination which is assisting unscrupulous speculators to gouge consumers in that state. Mr. Hultman declares that most of the communities listed are small and their situation "gives strength to the claim that small communities and small dealers are being discriminated against."

MISSOURI

The October grand jury, of which W. K. Kavanaugh was foreman, finished its report at St. Louis on the last of November, recommending that the City of St. Louis use a proper standardized form of coal contract on account of some alleged irregularities in the deliveries of coal in 1922. The jury heard a number of witnesses pertaining to 90,000 tons of 2-in. screenings pertaining to, but on which, it is claimed, a large tonnage of screenings as low as $\frac{1}{2}$ in. was shipped. This coal was for the Water Department. An investigation of the books, etc., did not justify indictments, but the jury strongly urged a rearrangement of contract forms.

MONTANA

Work was resumed at the Gilbert-Crawford operation, near Roundup, last March. The mine is electrically equipped throughout. Efforts for the present will be confined to development work, the running of the main entry and the opening of two entries on the east and two on the west side.

NEW YORK

Lucius W. Robinson, chairman of the Rochester & Pittsburgh Coal & Iron Co., announces the appointment of J. Noble Snider, at present coal traffic manager of the New York Central Railroad Co., as vice president in charge of sales, with offices at No. 1 Broadway, New York City. At the same time Mr. Snider announced the appointment of J. M. Nelson as sales agent at Buffalo; J. N. Terrio as sales agent at New York and Charles C. Schaefer as sales agent at Rochester. All appointments became effective Dec. 1.

Alex Bonnyman, chairman of the board of the various Blue Diamond Coal Mining properties, arrived in New York recently after a three months' visit to Scotland and Naples. He was welcomed home by his brother, James Bonnyman, head of the Blue Diamond Coal Sales Co. and formerly a large operator at Birmingham, Ala.

OHIO

The Atwood Coal Co., of Wooster, has been chartered with a capital of \$50,000 to mine coal and deal in coal and kindred products, both wholesale and retail. Incorporators: C. Otis Smith, Francis Zarlingo, Mabel C. Smith, F. M. Vanover and T. E. Steiner.

The operating offices of the Hocking Valley Products Co., large coal operators in the Hocking Valley, have been moved from Columbus to Logan. The sales end of the business has been taken over by the Jay Miller Coal Co.

Robert Farnier, vice-president of the United Mine Workers of Sub-District 5, has resigned, effective Nov. 15. The resignation came as a surprise to the miners in eastern Ohio. The understanding is that Farnier has been offered executive positions at the mines of several of the larger companies operating in the field.

H. C. Howland, formerly with the Packard Coal Mining Co., of Columbus, has been made manager of sales of the Wheeler Coal & Coke Co., of Columbus. W. C. McClanahan, formerly with the Kanawha Valley Coal Co., of Charleston, W. Va., has been employed as a salesman for the Wheeler Coal & Coke Co.

The Maple Grove Coal Co., of Columbus, chartered about six months ago, has just about completed its tippie at a new mine in Harrison County on the Wheeling & Lake Erie R.R., which will be placed in operation soon. The initial production will be about 300 tons daily, which will be gradually increased.

The State Industrial Commission, which has charge of mine activities, has started a campaign to prevent injuries to miners employed in all mining districts of the Buckeye State. The campaign will be largely educational and will be pushed in 33 counties where mining activities are carried on. Jerome Watson, chief of the Bureau of Mines, has interceded with federal authorities to have a federal mine-rescue car sent into the state to be used jointly by Ohio and Kentucky, which will move from point to point showing first-aid measures and safety plans of the federal and state bureaus.

PENNSYLVANIA

R. B. Mellon, of Pittsburgh, president of the Mellon National Bank and a director of the Union Trust Co., has been elected chairman of the Board of Directors of the Pittsburgh Coal Co., which office was made vacant several months ago by the death of M. H. Taylor. Mr. Mellon was elected to the board of directors to succeed his brother, A. W. Mellon, when he was appointed Secretary of the Treasury in President Harding's Cabinet.

The Marion Machine, Foundry & Supply Co., of Scottdale, has just completed a domestic coke preparation plant for the Mahoning Coal Co. at Alverton, near Scottdale. The capacity of the plant is about 300 tons per day.

John Callahan, formerly traffic manager of the National Coal Association and until recently associated with the Morrow-Callahan Coal Co., of Cincinnati, has become sales manager for the Keystone Coal Catalogue and Mining Directory, published by the Keystone Consolidated Publishing Co., of Pittsburgh.

An important coal land deal has been closed in Cambria County in which **John H. Weaver**, of Philadelphia, head of the Nant-Y-Glo Coal Mining Co. and the Monroe Coal Co., becomes the owner of 992 acres of valuable coal land, purchased from T. Stanton Davis, of Ebensburg. The consideration is said to be \$193,280. The deal affects only individual holdings of Mr. Davis and is not connected in any way with the Navy Smokeless Coal Co.'s holdings in the same vicinity. Two tracts are involved, one containing 736 acres and the other 256 acres. The smaller tract brought \$80 per acre while the larger tract brought \$200 per acre. The entire plot lies in Cambria township.

The Hillman Coal & Coke Co. has closed down its Pike mine, near Brownsville, for an indefinite period, and has resumed operations at the Jerome No. 2 mine in the Somerset County smokeless coal field, which has been idle for a couple months past. The Pike mine is in the Pittsburgh seam in Fayette County.

The anthracite companies of Pennsylvania are satisfied with the system of assessing the price of coal at the mines for state tax purposes, Auditor General Samuel S. Lewis said in reply to criticism of the Anthracite Bureau of Information and Samuel D. Warriner, who said that the state places a value on coal in excess of the price obtained for the coal. "The settlement of the anthracite coal tax is no different from the settlement of taxes on capital stock, loans and gross receipts," said the Auditor General. "At times the valuations are accepted by the fiscal officers and then again there are differences that are adjusted after hearing. I know of no differences with any of the coal companies. They have told me they are satisfied. The cards are all laid on the table and the public has been advised regarding all matters connected with the tax collection."

WASHINGTON

The Lisco Coal Co.'s property at Renton Junction has been completely unionized by agreement signed late in November. It is a small mine.

Chain Belt Co., Milwaukee, Wis., manufacturers of Rex chain, transmission machinery and conveying equipment, formerly represented on the Pacific Coast by Meese & Gootfried Co., San Francisco, has established direct factory branches and warehouses in Portland and Seattle. Arrangements also have been made with the Washington Machinery Depot, Tacoma, to carry a large stock of Rex chain and transmission machinery.

WEST VIRGINIA

J. M. Scott, general manager of the B. & O. Ry. stated on Nov. 24 that 32,000,000 tons of coal have been shipped over the Baltimore & Ohio from West Virginia to the Great Lakes this year. This is the greatest tonnage, he said, that has ever been shipped from the coal fields of the Little Mountain state to the lake region.

The R. M. Davis Coal Co., entertained many coal and railroad representatives including transportation and traffic managers of the Baltimore & Ohio, Pennsylvania, the Western Maryland, the Monongahela, Long Island, New York Central and Pittsburgh and Lake Erie railroads at Morgantown, recently. Speakers included Dr. I. C. White, state geologist of West Virginia; former Governor W. E. Glascock, and Thomas K. Maher, of Cleveland, Ohio.

The Laurel Run Coal Co., of Fairmont, has just been organized with a capital stock of \$20,000 with a view to operating in the Fairmont region. Fairmont is to be the headquarters of the company, which was organized by Thomas H. Laulis and James Laulis, of Shinnston; T. F. McIntire, Charles E. Potter and E. C. Frame, of Fairmont.

Harry B. Martin, of the Greenmar Coal Co., of Elkins, has been elected as a director of the newly organized Citizens National Bank, of Elkins.

The West Virginia Supreme Court has held in the case of Wells Goodykoontz and others against the White State Mining Co. that unless otherwise provided, there is an

implied covenant in every lease of land for coal and coking purposes; that the lessee will do nothing and leave nothing undone reasonably necessary to protect the inheritance against waste and destruction resulting from his operation on the land; that unless waived by the terms of the contract of lease, the lessor of land for coal and coking purposes has the right to sub-jacent support for all superincumbent strata of coal and may enjoin removal by the lessee of the mine props or pillars in the subjacent strata until the mineable and merchantable coal in the upper seams has been mined out by the lessee, or by the lessor after the term of the lease has expired; that if under such a lease the lessee has opened a mine in one or more of the mineable seams and has, in violation of his duty, neglected to protect the inheritance, which has resulted in the destruction of any part of the coal unmined, equity will require him to account to the lessor for the damages so sustained by him to the inheritance.

There were thirty-two fatalities in the West Virginia mines in October, all but twelve of which resulted from falling roof and coal. Of the remaining twelve deaths in and about the mines, five were due to mine-car accidents. One man was killed in a motor accident, one in a mining-machine accident and two by electrical shock. Outside the mines, one miner was killed in an accident on an incline and one in an accident in connection with the operation of an electric hoist. Seven of the thirty-two fatal accidents occurred in McDowell County, Logan County coming next with six and Mingo with four. In Monongalia County there were three fatalities and in the counties of Brooke, Fayette, Kanawha, Marshall and Raleigh two each. In the counties of Clay, and Ohio there was one fatality each.

WISCONSIN

The Carnegie and Great Lakes docks, located at Superior, have protested to the Superior City Council against the tax on railroad coals on their docks. They claim that railroad coal should not be considered in the same category as commercial coals. The docks threaten to change their port for storage of railroad coal unless the tax is dropped.

WASHINGTON, D. C.

Dr. Thomas T. Read, supervising mining engineer of the Bureau of Mines, has been awarded a gold medal and a commemorative diploma by the government of Brazil. Dr. Read was the representative of the Department of the Interior with the United States Commission to the celebration of the 100th anniversary of the independence of Brazil at Rio de Janeiro last year, and also was the special delegate of the American Institute of Mining and Metallurgical Engineers and the Federated American Engineering Societies to the International Engineering Congress held in connection with the celebration.

Representative Crampton, of Michigan, chairman of the subcommittee on appropriations for the Interior Department, spent a week recently at the Pittsburgh station of the Bureau of Mines. So that he may be fully acquainted with the activities of the Interior Department, Mr. Crampton has spent a large portion of the interim between Congresses in familiarizing himself with the field work and experiment station work of the various bureaus.

The Bureau of Mines has offered through the Washington University, of St. Louis, two scholarships in mineral economics to mining engineering graduates who have completed some work in economics. These scholarships, valued at \$1,500 yearly, will enable the holders to study for two years at the graduate school of Washington University in Washington, D. C., for a Ph.D. degree in economics. The students will work under the technical guidance of Bureau of Mines engineers.

George S. McCaa, engineer in charge of the Mine Safety Service of the Bureau of Mines, has resigned to enter private employment. Mr. McCaa, who is recognized as one of the foremost research men specializing on oxygen breathing apparatus, developed the half-hour type breathing apparatus for the Navy.

Following its custom of rotating its chairmanship among the Commissioners each year, Commissioner Huston Thompson on Dec. 1 became chairman of the Federal Trade Commission, to serve one year, succeeding Victor Murdock, who has been chairman for the past year.

CANADA

Roy M. Wolvin, president of the British Empire Steel Corporation, has announced the adoption of a pension system for retired employees. It is applicable to all male employees both of the steel and coal departments who have served twenty-five years and have reached the age of sixty-five, and to females who have served the same term and reached the age of fifty-five years, and to any employee who has been fifteen years in the service and in the course of his employment has become permanently incapacitated for further work.

Sir Henry Thornton, head of the Canadian National Railways, stated in Toronto recently that no more cut rates would be offered by the road on Alberta coal for Ontario. The last word has been said in regard to the matter, he said.

A report issued by the Dominion Bureau of Statistics on the coal industry in 1921 states that on Dec. 31 of that year there were 402 coal mines in Canada having an area of 713,434 acres, and 1,433,331 sq. ft. of underground workings. There were 168 stock companies operating 221 mines. The total par value of issued securities was \$138,986,473, of which \$86,727,930 was held in Canada, \$25,879,964 in the United States, \$18,721,941 in Great Britain and \$7,656,638 elsewhere. Capital employed in coal mines at Dec. 15, 1922, was placed at \$140,466,108.

William Sloan, minister of mines, has given notice of two bills that he purposes introducing at the meeting of the Provincial Legislature, now in session. The first is an amendment to the Mines Act, imposing greater penalties for infractions of the act. Thus, for example, the penalty for carrying matches and smoking materials underground will be increased from \$10 to \$100. The other bill, the imposition of a tax of 1c. per gallon on fuel oil entering British Columbia from foreign countries, is meeting with a storm of opposition by oil-burning industries. The tax is being imposed with a view to protecting the coal-mining industry of Vancouver Island against the competition of California and Mexican fuel oil.

Under the provisions of "An act to regulate the sale of coal" the Lieutenant Governor of the Province of Alberta has ordered that every operator in Alberta shall have a registered name for his coal, all coal shipped and sold by the operator shall be under such registered name; that every invoice and shipping bill and a card which shall be displayed on the car door shall state the name of the mine, district whence it is shipped, name and size of the coal and the date of shipping and destination. The regulations also provide that every dealer, wholesale and retail, selling coal produced in Alberta must keep a record of the coal purchased and sold from each mine; that all coal must be sold under its registered name and that an inspector at point of shipment shall have power to inspect any coal for the purpose of ascertaining whether the coal conforms with the bill of lading. Any operator, broker or dealer who violates the law, if found guilty, is liable to a fine not exceeding \$1,000 for each offense or imprisonment for a period not exceeding six months, or both.

The gist of a resolution recently passed by the local union of the United Mine Workers at Phalen provides that the provisional officers of District 26 serve notice on the operators of District 26 immediately to terminate the present contract when it expires on Jan. 15, that no new contract be signed which carries less than a 40 per cent increase in wages to contract workers and \$2 a day increase for datal men; that the conditions pertaining at the different collieries be written in the contract, and that the contract cover the same period as the contract covering the bituminous fields in the United States.

The coal production of the mines of British Columbia during October, 1923, totals 228,293 tons, an increase over the month of September production of 46,659 tons. Of the total production for the month, the mines on Vancouver Island produced 143,020 tons, approximately 63 per cent, and 21,140 tons over the production of last month. The Nicola-Princeton mines produced 22,232 tons, which is an increase of 3,254 tons over last month's production and approximately 10 per cent of the total production. The mines in the Crow's Nest Pass district produced 63,041 tons during October, an increase of 22,265 tons over last month and approximately 27 per cent of the total production. All the mines in the province showed an increase over last month's production.

New Equipment

New Line of Small Vertical Vacuum Pumps

A new line of small vertical belt-driven vacuum pumps known as Type Fifteen, announced by the Ingersoll-Rand Company, 11 Broadway, New York, is expected to be of interest to those who require high-grade standard reciprocating dry vacuum pumps of small capacities. The wide range of sizes and the different methods of drive offer a vacuum pump to suit any need where a high vacuum is necessary. Type Fifteen vacuum pumps will pull and maintain vacuums between 28.6 in. and 29.25 in., depending on their size. In addition to the standard belt design (Fig. 1) each size is built as a self-contained electric motor outfit, using the short belt-drive arrangement or driven through pinion and internal gear. The vacuum pump and electric motor of both the short-belt and gear-driven units are mounted on a metal sub-base, so that they are not dependent on the foundation for correct alignment.

The "Constant-Level" system of lubrication used on these pumps maintains a constant-level of oil, which insures the right amount being distributed to all parts. As in the ordinary splash

FIG. 1—BELT-DRIVEN VACUUM PUMP

These pumps are made in six different sizes—the 4x2 in.; 5x3 in.; 6x4 in.; and 8x5 in. single-acting pumps; the 10x5 in. and 12x6 in. double-acting pumps.

system, the bottom of the pump base forms an oil reservoir of sufficient capacity for the "Constant-Level" system. The amount of oil in this reservoir is determined by high and low level petcocks. Above the reservoir and directly underneath the connecting rod is a constant-level pan, as shown in Fig. 2, into which the connecting rod dips and distributes just a sufficient quantity of oil for proper lubrication. The constant-level pan is replenished

FIG. 2—SECTIONAL VIEW OF NEW VACUUM PUMP

A "constant-level" pan insures proper lubrication at all times, thus preventing scored cylinders and burned-out bearings.

with oil from the supply in the crankcase by a valveless oil pump operated by an eccentric on the main shaft. Regardless of the amount of oil in the reservoir so long as it is somewhere between the high and low level petcocks, this system will function perfectly. The lubrication of small vertical vacuum pumps employing the enclosed crankcase and splash system has often been a source of great concern. The tendency of oil systems has been to feed either too much oil, which will be carried out with the air, or too little, causing scored cylinders, overloads and burned-out bearings.

There are four sizes of single-acting pumps and two sizes of double-acting pumps. The single-acting pumps are

air cooled by means of an annular ring which encircles the cylinder, while the double-acting pumps are cooled by means of circulating water.

Car Door with an Ample Discharge Opening

When a car door is arranged to swing about a straight round bar joining the ends of the two sides of the car—is in short a simple pivoted, and not a lifting, endgate—the coal piled above the car body cannot get through the opening. Large lumps tend to stick and have to be barred loose, and the other lumps roll over the gate instead of sliding off the bottom, causing unnecessary breakage. Occasionally also coal spills over the side of the chute.

An endgate pivoted on the end of the car, which nevertheless gives an adequate opening for the passage of coal, is installed at the mines of the Legitt's Creek Anthracite Co., Scranton, Pa. It is made and has been patented by the Tubach Mine Car Door Co., of Dushore, Pa.

The pivot bar *A* is not straight. As may be seen in the illustration, it bends down in a U of rectangular form between the two hinges *B. B.* When the door opens the U swings up till upside down, raising the gate clear of the top of the car about 12 in., thus giving an opening through which all the coal can pass without barring.

Nothing remains but to describe the way in which the door is kept closed and is opened. When closed the straps, *E*, which extend below the door, catch in the stops *F*, and these keep the door tight until the handle of the latch or right-angled arm *D* is lifted. That clears the bearing plate at its angled turn, releasing the arm *C*, which forms part of the pivoting bar *A*. This enables the arm *C* to turn and so makes it possible for the whole bar to revolve on the hinges *B*. That being so the bar can rise and the door with it. The door is thus freed from the catches and is swung open and upward by the pressure of the coal. All therefore that is needed is to lift the latch *D* by the handle and tip the car over at the dump. The door then opens itself, and the coal is discharged without barring.

DOOR WHICH BOTH SWINGS AND IS LIFTED

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 24

NEW YORK, DECEMBER 13, 1923

Number 24

The President on Coal

PRESIDENT COOLIDGE did much with coal in four short paragraphs in his first message to Congress. He took a strong position in favor of private management and against government ownership or operation. But private owners, he points out, must recognize the paramount public interest in their business and conduct themselves accordingly. He puts it up to the industry to correct its abuses. He urges as of exceeding importance legislation giving the chief executive wide power over coal in times of national emergency. He strikes a popular chord when he says the cost of coal is "unbearably high," but unless he was saying that wages behind that cost are too high, he was not thinking of bituminous coal. We can see nothing in his message to indicate that the administration sees coal as a subject of major political importance. Congress, and certainly Pinchot, so see it, but the urge, it seems, will not come from the White House.

Without giving a blanket endorsement to the recommendations of the Coal Commission, the President singles out several on which to put his stamp of approval. He leaves to Congress the details with no citation of urgency on any save that of giving the President emergency power. His last words deserve special note: "Those who undertake the responsibility of management or employment in this industry do so with the full knowledge that the public interest is paramount, and that to fail through any motive of selfishness in its service is such a betrayal of duty as warrants uncompromising action by the government."

The Inarticulate Public

MEETINGS convened to discuss coal take on some of the attributes of the attractions at county fairs. The same bunch of side shows, the same merry-go-rounds, the same games of chance move from fair to fair. At the coal meetings the erstwhile Coal Commission, the Geological Survey, the Department of Commerce, and the Federal Trade Commission always are represented. Among the observers at each meeting will be found familiar faces of representatives of the Bituminous Operators' Special Committee, of the trade press, of the anthracite operators and of the United Mine Workers of America.

While this situation brings out joking remarks on the part of those who attend many of these gatherings, they are not losing sight of the fact that these assemblages are significant of the activities in connection with the building up of a public opinion in respect to coal. There are many evidences that the public is becoming better acquainted with that commodity. Debating societies throughout the country are finding coal a fertile field for such discussion. Some student in

each university in the country has chosen coal as the subject of his doctor of philosophy thesis. The newspapers are showing an increased understanding of the fundamentals in the industry. Three years ago it was necessary to put "overdevelopment" in quotation marks and explain what was meant. Today the man in the street is acquainted with a large amount of detail as to the conduct of the coal industry. Progress is slow but it is moving, unquestionably, in the direction of an informed public opinion.

Officials around the Interstate Commerce Commission, for instance, are inclined to attach significance to the fact that the public is not interested greatly in coal because few witnesses appeared at the hearings at which the reasonableness of anthracite freight rates were being considered. They are overlooking the fact that the individual is not prepared to make the financial sacrifice necessary to prepare an argument and present it at such a hearing. If he did go the railroad lawyers would entangle him. The individual consumer of coal is very much concerned in the treatment he is receiving from the industry. These individuals are not organized and have difficulty in obtaining even local or neighborhood co-operation. Nevertheless in the aggregate they constitute a force capable of shackling any industry. The hope of the industry lies in the acquainting of those consumers with an accurate knowledge of the business so that they may not support unsound policies purported to be in their behalf.

Earnings

IT HAS long been the theory that wage rates as between anthracite and bituminous coal should be so pegged that the longer working year of the hard-coal worker would give the same annual earning power as the shorter year in soft coal. That is, anthracite rates have for years been lower than in the union bituminous-coal region. It is now possible to obtain a reliable check on how this theory has worked out, for with the interpretation of the Coal Commission's earnings studies, as published in this issue, we have comparable figures of annual earnings for the major classifications of coal-mine workers.

Contract miners in the anthracite mines in 1921—a normal year—averaged 250 days' work and earned \$1,922 on the average. In the soft-coal regions in 1921—a year of little work—the union tonnage men, including machine men, loaders and pick miners, averaged 134 days and \$1,034, compared with 151 days and \$1,051 at the non-union mines. Even in 1920—a year of high production—the soft-coal tonnage men, who worked an average of 220 days and earned between \$1,750 and \$1,800 on the average, fell behind the hard-coal contract miners. Governor Pinchot last September gave the anthracite tonnage men an increase of 10 per

cent over these figures, thus bringing their average to nearly \$2,200 per year, some \$400 per year above the general average for the soft-coal tonnage men in a good year. With this increase the *average* contract miner in the anthracite region has a higher earning by some \$200 than the *full-time* tonnage worker in soft coal. Before the recent 10-per cent advance the average daily earning of the anthracite contract men was approximately the same as that of tonnage workers in the bituminous-coal mines.

It is on this accounting that the union will base whatever demands it may make next spring for an increase in wages for the soft-coal miners. It is this advantage possessed by the anthracite tonnage men before Pinchot interjected his 10-per cent increase that gives significance to the gratuitous boost of last September. The soft-coal tonnage workers are still further behind. What is more natural than that they will want to overtake the worker in the anthracite region?

Looking at the day worker, we find the opposite picture. Here the earnings of the hard-coal inside man are from \$1.75 to \$2.25 per day less than in the bituminous-coal regions. The hard-coal day worker in anthracite averaged \$1,480 in 1921, against \$1,293 in the union and \$1,125 in the non-union soft-coal mines, but compared with \$1,600 in 1920, a year of better working time. Full-time workers paid by the day inside the soft-coal mines earned \$1,850 in 1920 and between \$1,510 and \$1,600 in 1921. Likewise the outside day men around the bituminous-coal mines, with earnings of from \$1,700 to \$1,875 in 1920, are better off than the same class of workers at the anthracite mines, who with the 10-per cent increase will average about \$1,450.

It were much better that the coal industry correct such irregularities in rates as may have brought about these variations in earning power by peaceful discussion, by that process which the United Mine Workers hug so closely, in name at least, collective bargaining, than that they resort to the strike.

The mine workers alone are organized to give constructive direction to the correction of existing scales. Is the problem too large even for them?

More or Less Domestic Coke

ANTHRACITE finds one of its chief competitors in various kinds of coke—gas or byproduct coke—and may later find it in coke prepared by the low-temperature distillation process. Judging by what has been written and by what some have feared, the anthracite industry has before it some extremely formidable competition, and that without at all belittling the effect of coke on the volume of present-day sales of anthracite.

However, a significant, if somewhat feeble, department of the American Gas Association is the "Complete Gasification of Coal" Section. At the convention of the association in 1921 President Monroe said: "Some of you gentlemen are going to be able to give us a gas from raw coal of 420 B.t.u., and we are going to have no byproducts to handle or sell; nothing but ashes to take away. When you give that to us (and you are going to give it to us within the next five years) the problem of the owner of a gas property will be much simpler than it is today, for now when he makes coal gas he is left with an enormous quantity of coke as

residue, which puts him into a business which takes a far larger annual turnover than his mere gas production."

Unfortunately, according to L. P. Willien, even using oxygen 90 per cent pure he cannot make a gas by complete gasification of his coal that will meet the requirements of the consumer, and such gas would need enrichment with oil. However, the proposition is brought measurably near by the use of oxygen instead of air, and the process of making oxygen is now so cheap that the use of an inferior oxygen looks not entirely impossible. Nevertheless to bring the gas thus made to 500 or 550 B.t.u. would require 2 to 2.75 gallons of gas oil per thousand cubic feet.

Apparently the prospect of making a commercial product with the aid of a little oil or with a somewhat lower standard of thermal value in gas is not so far distant as to make it unworthy of consideration. The coal probably would be first carbonized, then gasified by combustion in the presence of steam and oxygen. Either oil gas will be added or else the coal gas will be sold without enrichment.

In any event only ashes will remain and the position of anthracite will be improved by the removal of coke from the domestic field. To show how oil gas is improved by the use of oxygen of the purity mentioned, gas prepared by the use of air and the Dayton process had 60 per cent of nitrogen and a thermal value of 500 B.t.u. per thousand cubic feet, whereas when prepared by the same process with oxygen 90 per cent pure the nitrogen fell to 4 per cent and the thermal value rose to 1,210 B.t.u.

AS A RESULT of government operation the coal production of Russia has fallen to 72 tons per man per year. To get the tonnage of 1918 with such inefficient operation the United States would need 9,400,000 men. If all the coal-mine workers in the United States were to combine their efforts to getting out anthracite and were to be no better skilled at doing so than the Russian employees of the coal mines we would get less than 50 per cent of a normal year's production of anthracite—no bituminous coal whatsoever. The Russian workmen under their benign government produce one ton of coal every four days. If the United States mines were run like those in Russia and had a production of coal equal to that reached in this country in 1910 it would be necessary for one man in four to be engaged in producing coal. All this is based on information afforded by the Soviet Government.

"BROTHER CHARLEY" BRYAN, Governor of Nebraska, now modestly offers himself for the Presidency, with "soft coal 25 per cent cheaper at the mines" as one of his planks. If he could run a mine so as to do that, five thousand bituminous-coal operators out of a total of five thousand, looking back over the past six months, would like to hire "Brother Charley" to operate their business for them. Possibly he has in mind inviting the country's householders to go down and pick loose their winter's supply. It is fortunate that political gas isn't blackdamp.

EVEN THOUGH HENRY AND EDESEL have gone into coal mining, National Coal Association statistics show there are fewer Fords in coal camps than ever before.

*Loaded Cars Approaching Dumphouse**

Biggest Problem at Lynch Is Haulage of Coal; How Its Large Output Moves to the Tipple

Haulage as Well as Extraction Needs Considered in Planning Layout of Producing Sections of Mine—Standardizing Output Units—Mules and Ponies Used—Grades Too Steep for Battery and Reel Locomotives

THE importance of the Lynch system of haulage is such as to warrant its having first place in any description of that operation. Main headings—by that is meant headings from which the mine areas and their headings are laid off—are being extended not necessarily to pierce the center of the property or to run parallel to either of its gravimetric axes but rather so as to facilitate haulage and to equalize production over the life of the mine, the property being subdivided in a manner that will provide mine areas giving approximately equal tonnage. For this reason we do not find in the Lynch mines on each side one main heading over which all coal comes but rather main headings off main headings, and from these are driven the customary haulageways and room sections which tap the mine areas.

Principal headings are driven as straight as an arrow. In a distance as much as two miles the center line of these principal headings converge or diverge no more than a fraction of an inch. Because of this accuracy in giving sights for projections, a transit set in the mouth of No. 30 mine would cut every spad in a single sight were it not for the varying gradients and the inability of the eye to penetrate that distance.

In the principal haulage roads top is brushed and bottom is lifted to produce a gradient usually of no more than $1\frac{1}{2}$ per cent in favor of the loads. Room headings are graded from haulageway to haulageway successively, as is to be expected, because the coal which

lies between consecutive haulageways is mined out in about two years and the locomotive cannot pick up a full trip from the necks of the rooms lying in the intervening distance.

To simplify matters, I have chosen to describe only the system of haulage in No. 30 mine, which corresponds with that employed in No. 31 mine. By referring to the map of the mine on page 999 it will be seen that the greatest development is in two areas off No. 1 haulage right, which roadway has been driven to its western extremity. Most of the coal to the north or right of this heading has been mined.

No. 7 flat left, which is the barrier heading for the double mine area shown, is one of the main haulage arteries. No. 7 flat left and No. 1 haulage right each is provided with an empty and a loaded track. The development along the main heading is not as great as it is along No. 1 haulage right and consequently one track in it serves for both loads and empties.

The Lynch system of haulage owes its success to a minimizing of interference between trips of loads and of empties. This is obtained not entirely by resorting to individual tracks for travel in opposing directions but by routing and scheduling all trips so that they will be where the others are not, so far as is possible. Further refinement in haulage is obtained by the observance of rules laid down by the management. Thus at crossovers a loaded trip has the right-of-way. Trips on down gradient are given the same preference by trips traveling on the level or on an upgrade. All this applies to main haulage roads.

Wherever possible haulage is directed in loops. The best illustration of this is the route of trips traveling

*Headpiece shows loaded trip coming from No. 30 mine. The mine cars filled with coal go through the rotary dumps and are discharged. They then run to a track and are made up into a trip by a mechanical trip maker and dropped by gravity to the storage track beyond.

Standard and Trial Car

The standard car is the one to the right. As an experiment the shorter, higher car on the left was built at Lynch, the journals being provided with vertical springs to make the car less rigid when passing over low places in the track. The standard car, however, gave better service.

Empties to the rooms driven to the right of No. 7 flat left are delivered through the first room heading on that side directly from No. 1 haulage right. But loads coming from this side are directed toward and over No. 7 flat left. After this room heading is closed by the encroachment of the robbed area upon the barrier section, empties will travel over the route taken by the loads. Then switches will be laid to connect the empty track of No. 7 flat left with haulageways right. These switches are shown in place but in reality they have not yet been laid, as the loop now used makes them unnecessary.

Trips are handled in somewhat the same manner in typical single mine areas as in the double mine area just described. Single mine areas are shown by *ABCD* and *AFED* in the mine plan. In these mine areas rooms are located on one side only, so that two tracks in the main headings of these areas are not needed, at least for the present. Loads and empties travel over one track throughout these mine areas.

ONE TRACK WILL SERVE FOR 1,000 TONS DAILY

A production of about 1,000 tons per day from one mine area can be handled over one track in the main heading of that mine area. For a much greater tonnage in a mine area, as in the double-mine area, individual tracks for loads and empties become necessary. Also two tracks will be requisite in the main heading

of a mine area producing 1,000 tons of coal per day when the live workings of that mine section move so far in by as to require the services of more locomotives. This must be recognized, for the mine areas are to be worked to the boundaries for distances of three miles or more.

A single-mine area, which is the one commonly used in the Lynch mines, is preferable to the double-mine area for the reason that it can be ventilated with only one overcast. Where the air splits to the right and left, as it inevitably must in the double area, in accordance with the system of ventilation at Lynch, an overcast is required at every haulageway that crosses the return airways. The general paths of ventilation are such that the air is forced to the advanced workings first and is then made to sweep the goaf line outby.

For gathering loads and distributing empties in room headings and for tramping to and from the tippie twenty-five 13-ton trolley locomotives are provided. During the month of May, 1923, the average daily output for each was 250 tons. The production per day has not yet reached the combined capacity of these locomotives.

Seeing that haulage roads cannot be graded everywhere to favor the loads owing to the rolls in the floor of the Lynch mines, the average daily output during the month of May per locomotive is substantial enough. Especially is this true because these locomotives must

Loading Mine Car in Heading

The top of the car 22 in. above the rail. The body is built so that the bottom is below the axles, the wheels being covered by steel plates. The reader will note the prop always in position in the center of the roadway and the three electric lights on the side of the road.

TRACK LEADING TO DUMPHOUSE, NO. 31 MINE

Rotary dump can be seen opposite each track. Roads are periodically cleaned and fishplates tightened.

gather from in front of the room necks and also tram the loads to the tipple.

In a time study the average time of all locomotives in seven mine areas for making a round trip was determined as 81 minutes. When hauling trips of 20 mine cars an average of at least six round trips can be made by each locomotive, allowing ample time for delays.

DO NOT PERMIT LOCOMOTIVE TO BE OVERLOADED

As a general rule no single trip is allowed to have more than 25 mine cars. For long hauls as many as 30 mine cars sometimes are permitted. The company has learned that on short hauls more coal can be pulled by a given number of locomotives when the trips are small and made frequently than can be hauled in trips of maximum size which are continually stalling. Fewer mine cars are needed, for fewer are in transit than is

TRIP MAKER AND TRACKS, EMPTY SIDE, NO. 31 DUMP

In addition to the moving dogs on the chain in the middle of the track, dogs on fixed pivots are placed in either side of the roadway, making it impossible for a mine car to break away and run into a car coming from the dump.

the case where large trips are in use, and of course, locomotives need fewer repairs under such circumstances.

A novel system of rating is used at Lynch for stimulating the interest of motormen in the care of their locomotives. Each month on a day chosen at random the chief electrician inspects each motor and gives a percentage rating on its condition. If the rating of any one motorman falls below the average he is censured. Repeated failures are just causes for dismissal. Semi-annually cash prizes are awarded for the best record. This practice creates greater interest in the care of locomotives. Rivalry to excel, however, is a greater incentive than is the cash prize.

Locomotives are inspected and lubricated every night. Motormen are instructed to use an air line for cleaning out motors and other moving parts. For this purpose such a line is located on the empty track on the far end of each trip maker on the empty side of the dump-houses. Locomotive bumpers are cleaned by air three

TROLLEY WIRE AT A TURNOUT FROM MAIN HEADING

The supports are so accurately located that the wire is practically parallel with the curve of the track. The hangers are held by long drift pins which never come loose unless the roof falls.

times each day in order that a sure footing may be provided for brakemen.

Conditions do not favor the use of storage-battery or reel locomotives in these mines, for the rolling bottom prevents them from being used with efficiency. This fact has been confirmed by giving two battery locomotives and one reel locomotive a fair trial. On Feb. 12, 1923, the output of the three locomotives combined was 482 tons. Seven drivers working under average conditions in the mines could produce 500 tons in one day.

The average output per driver for the three sections worked by these gathering locomotives is 76.5 tons per day. Just 6.3 drivers under identical conditions could gather as much coal as the three locomotives. The reel locomotive has given better service than the two battery locomotives. This would indicate that in a non-gaseous

mine a reel locomotive is better suited for gathering than a battery locomotive.

In the Lynch system of haulage no sidetracks are necessary. Mine cars are pulled from the face of rooms onto the room heading by mules, ponies or room hoists. Neither animals nor room hoists pull the mine cars beyond the point in the heading adjacent to the room neck. The utility tram and gathering locomotives gather the mine cars which stand on the entry near the room neck and haul them to the tippie. Consequently the trolley is extended as the heading advances, and power is thus brought to the faces of headings.

Ponies are utilized in places too low for mules. To take care of 64 working places, which is the average number for a single mine section of two room sections, about 12 mule drivers must be employed. Single mules are used for gathering in a few of the places but generally two or three are required, for the rooms are likely to have dips as steep as 6 per cent. The average number of mules handled by each driver in the mines is 2½. The drivers handle an average of 72 tons per shift, both mines being considered in establishing that figure. Where the grades are greater than 6 per cent room hoists are used instead of animals.

In the Lynch mines 75 room hoists are in use, 57 of which are driven by 7½-hp. motors, 18 being equipped with motors of 3 hp. Experience at Lynch proves that for grades from 6 to 20 per cent or more the standardization of hoists to one size, driven by the larger motor, is advisable. A ⅞-in. 6-strand 19-wire rope of plough steel with a length of 500 ft. is used on each hoist. Its average life is 60 days.

TRACK THROUGHOUT IS HEAVY AND WELL LAID

Tracks in principal headings, including barrier headings, are laid with 60-lb. steel and all curves have a 300-ft. radius. Tracks in room headings and cross-haulageways are laid with 40-lb. steel, the curves being struck on radii of 150 and 200 ft. respectively. Room track is of 20-lb. steel. The combined length of the tracks laid with 60 and 40-lb. steel is 37.92 miles. On all haulage wooden ties are used set on 2-ft. centers. In the rooms the ties are of steel and are spaced 3 ft. apart.

The time spent in elevating track on curves is time wasted wherever the speed is no greater than 15 miles per hour. This is the common belief of railroad engineers and of the United States Coal & Coke Co. The elevation is not needed if the track is otherwise correctly laid.

Promiscuous placing of timbers on haulage roads is not tolerated under any circumstances. The general superintendent of the company is consulted regarding cases in which set rules do not apply or, where action must be taken under short notice, the chief mine inspector directs the work. Timbers are never placed where there is any danger of their being knocked loose by derailed rolling stock.

Brake shoes of cast steel have preference over those of wood. They are more effective, are replaced with less labor and have a longer life. Under the severe service in the Lynch mines their life is 8.75 months as against 12 to 14 months in the mines at Gary, W. Va. A man without any assistance can replace a brake shoe of cast steel in 30 minutes.

The Lynch system will give to those who use it a measurable degree of regularity in mining each section

of the mine. The operation will embrace as many sections as are needed to produce a given tonnage. Each is a mine within a mine. To all is allocated a specific daily tonnage (1,000 tons at Lynch) and this is to be maintained until the sections are mined out whether the working places be a half mile or five miles from the tippie. The ventilation that is provided and the haulage roads that are built will last the life of each mine area. Rooms follow close behind the advancement of headings. Stretches of room headings are advanced quickly and as quickly worked out.

As the live workings move further and further away from the tippie, the method of mining does not change, and the same number of working places move away from the tippie, the length of haul becomes greater. Consequently more mine locomotives and haulage attendants are needed. Nevertheless the system of haulage is in no wise changed. Empties are brought to the rooms in the same manner as at the commencement of the mine area. One haulage road carries all the coal coming from the mine area it serves.

Production of Coke in September Declined 248,000 Tons

Production of coke in byproduct ovens continued to decline slowly during September. The total output for the month, was 3,112,000 net tons. The daily output was 103,729 tons, as against 104,402 in August, a decrease of 0.7 per cent. Of the 70 plants, 65 were in operation and 5 were idle. The coke produced was 85.8 per cent of the present capacity of all the plants. Production from beehive ovens also declined. The month's output of beehive coke is estimated at 1,373,000 tons, as against 1,494,000 tons in August. The total output from both types of ovens declined from 4,733,000 to 4,485,000 tons.

The decreased activity in coke manufacture reflected in part a decline in the output of pig iron and steel, in part the settlement of the anthracite strike. These statistics of byproduct coke production are based upon reports to the Geological Survey from all operators of byproduct ovens, including merchant plants and plants engaged primarily in supplying gas for municipalities.

MONTHLY OUTPUT OF BYPRODUCT AND BEEHIVE COKE IN THE UNITED STATES (a)

(In Net Tons)

	Byproduct Coke	Beehive Coke	Total
1917 Monthly average.....	1,870,000	2,764,000	4,634,000
1918 Monthly average.....	2,166,000	2,540,000	4,706,000
1919 Monthly average.....	2,095,000	1,638,000	3,733,000
1920 Monthly average.....	2,565,000	1,748,000	4,313,000
1921 Monthly average.....	1,646,000	462,000	2,108,000
1922 Monthly average.....	2,374,000	669,000	3,043,000
July, 1923	3,267,000	1,582,000	4,849,000
August, 1923	3,239,000	1,494,000	4,733,000
September, 1923	3,112,000	1,373,000	4,485,000

(a) Excludes screenings and breeze.

To manufacture the coke produced in September required the consumption of approximately 6,637,000 tons of coal, of which 4,471,000 tons was charged in byproduct ovens and 2,166,000 in beehive ovens. The coke industry thus absorbed about 14.4 per cent of the coal produced during the month.

ESTIMATED MONTHLY CONSUMPTION OF COAL FOR MANUFACTURE OF COKE (a)

(In Net Tons)

	Consumed in Byproduct Ovens	Consumed in Beehive Ovens	Total Coal Consumed
1917 Monthly average.....	2,625,000	4,354,000	6,979,000

August, 1923	4,654,000	2,356,000	7,010,000
September, 1923	4,471,000	2,166,000	6,637,000

(a) Assuming a yield of merchantable coke of 69.6 per cent of the coal charged in byproduct ovens, and 63.4 per cent in beehive ovens.

WHAT do coal miners earn? This has been, second to none, a controverted point in every flare-up of labor trouble and in every discussion of the coal industry. The rate per ton for digging coal and the rate per hour for company men are recognized as inadequate measures of the mine worker's income, for in the soft-coal mines the irregularity of operations is notable. The year's income pays the bills.

The Coal Commission made the most elaborate study of earnings of coal-mine workers ever undertaken; a study, it is believed more detailed and comprehensive than any ever undertaken for any other industry. The Commission reports, one each for earnings of anthracite and for bituminous coal-mine workers, are a mass of figures, without interpretation. At a recent session of the American Academy of Political Science devoted to coal there

were almost as many interpretations of the Coal Commission's investigation of earnings as there were speakers. One interpretation was authoritative, because it was made by Miss Anne Bezanson, associate director of the Industrial Research Department of the Wharton School, who had charge of this work for the Coal Commission. The article that follows was prepared by her for the Academy but is first published here.

What the Coal Miner Earns

In Bituminous Coal Mines Earnings per Start Are Higher Than in Anthracite Operations—Hard-Coal Miners Have More Opportunities to Work—Labor Turnover Higher in Soft-Coal Industry

BY ANNE BEZANSON

Prefacing her paper Miss Bezanson said:

THE subject of the earnings of coal miners is a large one to cover in a short paper. There are some one hundred odd separate occupations for men engaged in and about the mine of an anthracite colliery. While the number of occupations is somewhat less in bituminous, the diversity of occupation is still very considerable. The U. S. Coal Commission found it necessary to separate forty major occupations in anthracite and twenty in bituminous mines in order to study even

the most important differences in earnings groups. This paper, therefore, can deal only with the most salient conclusions for the main occupational classes. Three things should be kept in mind in using the earnings tables prepared by the Coal Commission:

- (1) The tables as published do not show annual earnings.
- (2) The data were purposely compiled to stress any existing variations in earnings within occupations.

- (3) The scope of the study did not allow time for analysis and interpretation of data at the time of publication.

The earnings tables of the Coal Commission were prepared to show in considerable detail, the relation of earnings to time worked. The earnings for individual employees were grouped in intervals of \$100 for amount received while employed at one mine. Such a grouping was planned to bring out differences in earnings where such differences existed for the same occupation. The figures given are not, therefore, the

FIG. 1

Tonnage Workers

This diagram shows that tonnage men in anthracite mines work more days per year to get the same earnings as soft-coal miners. Thus in 1921 a hard-coal miner worked 270 days for \$2,800, a soft-coal miner about 230 days. Union and non-union bituminous-coal workers had approximately the same earnings.

annual earnings of any employee who shifted during the year. In attempting in this paper to give summary figures for earnings, I am obscuring the variations upon which the Coal Commission reports tend to lay most stress.

It should be remembered also that the Coal Commission were necessarily occupied with an enormous problem of collection and tabulation. In getting together the mass of data it

was more important to provide the primary facts than to get a few outstanding but over-summary conclusions. Everyone recognizes the necessity of sifting and interpreting statistical data collected in this way. However, the enormity of the task of tabulating earnings material did not leave sufficient time after the tabulation was done for detailed interpretation of all the data. The figures will, therefore, be the basis for

discussion for some time by students interested in careful study of the problems of earnings in coal.

Three facts should be borne in mind, in using the summarized data: (1) That one is obscuring important variations; (2) that the earnings figures must be interpreted in connection with the wage rate, turnover and irregularity studies of the Commission, and (3) that the figures do not give annual earnings.

EARNINGS in the coal industry can be summarized for three major occupational groups: The piece work, or tonnage, occupations in anthracite collieries comprise the contract miners and their laborers; in bituminous mines there are three important groups, *machine miners*, engaged in operating the coal undercutting machines; *pick miners*, engaged in undercutting by pick, and shooting and loading their own coal; *loaders*, engaged in shooting and loading the coal that has been undercut by the machines.

About 28 per cent of all employees in anthracite, and 16 per cent in bituminous work on the surface and will be referred to as *outside daymen*. The men engaged in haulage, maintenance of the way, and regulations of ventilation are generally paid on an hourly basis and are referred to as *inside daymen*.

Earnings of Tonnage Workers Compared.—It is well, first, to consider the relation of earnings for tonnage workers in the anthracite and bituminous industries. The accompanying diagrams facilitate comparisons. They show, for instance, the relation between time worked and earnings of contract miners in anthracite and of all tonnage workers in bituminous coal. Fig. 1 compares the time worked in a year with

dollars earned by contract miners, non-union tonnage men and union tonnage men. The curves show striking differences in the number of days worked to make the same annual earnings. It is apparent that for earnings up to \$800 per year, the time worked by union tonnage men and anthracite contract miners is almost identical. Above \$800, tonnage men in bituminous coal fields work fewer days to make the same earnings as contract miners in anthracite, the greatest difference being found at the \$1,800 division, with a range of 50 days in working time. The similarity of days worked to earn up to \$800 is surprising when compared with the wide difference in time for higher earnings.

One would have expected the bituminous curve to be below the anthracite curve throughout. Two causes account for the discrepancy; first, the turnover is higher in the bituminous group. This means that a relatively large number of men in the bituminous industry remain only a few days on the payroll of one mine. The earnings tables indicate that men do not make normal earnings in the industry until they have been a considerable time in the employ of one mine. The weighting of the bituminous curve with this group of short service workers tends to increase the time worked and brings the curve closer to the anthracite curve. The

FIG. 2

Union

Up to about \$3,000 per year union machine men make higher earnings for the same days worked than loaders or pick miners. Loaders and pick miners earn at about the same rate. Above \$3,000 per year pick miners make the most per day worked.

FIG. 3

Non-Union

Non-union tonnage workers earning above \$1,000 per year work fewer days than anthracite miners did in 1921. Above \$2,400 per year pick miners in the non-union fields have the higher rates of pay. Below \$1,000 there is little difference in rates of earning.

second cause is of equal importance; namely, that the average length of start is shorter, if considered throughout the year for all mines, in the bituminous coal industry than in the anthracite field.

Turning to the curve of tonnage men in the non-union field, it is apparent that to earn up to \$1,000 per year, tonnage men work more days than either anthracite or union bituminous-coal mines. Attention is directed to the earnings above \$3,000, showing non-union men working fewer days for the same dollars as the union area. Here, however, the number of men involved is inconsiderable. The important stress in this comparison should be put upon the space between the curves for days worked in anthracite and bituminous coal.

It is notable that anthracite contract miners who earned \$3,200 worked but ten days more than those earning \$2,000. This indicates a rather wide variation in the opportunity for earning among men working almost an identical number of days. The comparison also indicates clearly that earnings per start are higher in bituminous than in anthracite.

Figs. 2 and 3 show the earnings for separate tonnage occupations in the bituminous coal mines. Pick miners and loaders in the union group earn at about the same rate, while machine miners have higher daily earnings and work fewer days for the same annual total throughout than either loaders or pick miners.

Big Earnings in Anthracite.—This comparison, however, disregards the number of men involved in the industries. The only factor that has so far been considered is the number of days worked to make a given unit of earnings. When one takes into account the number of men involved, the anthracite industry makes a more favorable showing, since the opportunity for employment is greater. Figs. 4 and 5 show that the bulk of contract miners earn above \$1,000, whereas in the bituminous-coal industry more of the tonnage men have low earnings than high, and the curve slopes off

gradually, containing fewer men as the higher earnings groups are reached. The anthracite curve, on the contrary, decreases gradually in the number of men involved in each interval to \$1,000, and then begins to increase, reaching a high point at about \$1,800 to \$1,900. Even if the year 1920 is taken for the bituminous-coal industry, instead of the inactive year of 1921, the curves show the same general outline, although the numbers of men making the higher earnings are then more significant. This raises the question of the actual average earnings.

Average Yearly Earnings in 1921.—What then, is the average number of starts made by contract miners? What was the average annual earnings in 1921? How do these earnings compare with annual earnings for all tonnage men in bituminous mines? For the year 1921 the average time worked by contract miners in anthracite was about 250 days. The average earnings for that year was between \$1,900 and \$2,000—to be exact, \$1,922. The union soft-coal miners averaged about 134 days in 1921, a year of inactivity; non-union men made a somewhat better showing, with 151 days. The average earnings for tonnage men in both union and non-union groups was between \$1,000 and \$1,100—to be more exact, the figure was \$1,034 in union and \$1,051 in non-union mines.

Average Yearly Earnings in 1920.—The average days worked in 1920 were 219 for union soft-coal tonnage men and 221 for non-union tonnage men. This gives average earnings of \$1,750 to \$1,800 in the year 1920 among bituminous-coal tonnage men. It should be noted that the average starts made are about thirty less (roughly one month) than the average starts for anthracite miners in the year 1921, with a difference in earnings of \$156 in favor of the anthracite contract miners. It is understood that all these comparisons in anthracite are made for a period before the present 10

per cent increase in rates. It should be understood, also, that these are not the average earnings of full-year men but a figure which is based on all tonnage workers. The figure for earnings of full-year workers in anthracite is not available. In bituminous mines the average earnings of full-year employees is about \$400 higher than the figure for average earnings of all employees, or about \$1,425 to \$1,450 for tonnage men in 1921 and \$2,025 to \$2,075 in 1920.

Contract Miners' Laborers.—Contract miners' laborers in the anthracite industry should not be compared with any of the occupations in the bituminous-coal industry. They work for the miner, and are paid a proportion of the miner's gross earnings. This group shifts more than any other men in any part of the coal industry. Too few of these laborers remain on the payroll of any one mine throughout the year to give a figure upon which to base annual earnings. The figures as collected by the Coal Commission show earnings of miners' laborers of \$1,200 for about 200 days' work. There is no reason to think that this is the average working time of contract miners' laborers, since there is a real shortage of laborers and little time is lost in shifting from job to job. It should certainly be fair to take the average days worked by contract miners, and the average daily earnings of the laborers which is \$5.87, and arrive at a figure of income which gives \$1,468 for the year 1921. This is, however, an estimated figure, and is not arrived at by the careful calculations upon which the other figures are based.

At this point I may say that the average earnings in this paper are net earnings derived from the tables published by the Coal Commission, as are the average days worked. The figures were then checked by using the average daily earnings found by the Wage Rate Section of the Coal Commission and the number of employees involved were checked with the turnover figures. This makes three sources for verifying the

final conclusions, and it is fair to add that the computations agree very closely, there being a difference of only a few cents in the daily earnings as computed from the data from these different sources. Averaging the earnings of contract miners' laborers and contract miners gives an average earning for all tonnage workers in anthracite mines of about \$1,780 in 1921 for an average working time of 250 starts.

A further summary comparison is possible in connection with the earnings of tonnage men. When weight is given to the number of men in each \$100 interval of earnings an average earnings figure per start of \$7.75 to \$8 is obtained for anthracite contract miners and all unionized bituminous tonnage workers, there being a difference of only 4c. per day in the average earnings per start for these two groups in 1921. In the non-union field the average earnings per start is about 75c. less than in either anthracite or bituminous coal, falling between \$7 and \$7.25 per start.

In the discussion up to this point, the earnings of the men engaged in actually mining coal have been covered. The tonnage group constitutes almost three-fifths of all employees in bituminous and slightly over two-fifths of anthracite employees. The remaining employees are divided into outside and inside day occupations. The employees paid by the hour normally work more days in a year than the tonnage workers.

Earnings of Outside Daymen.—No comparison should be made between anthracite and bituminous coal for outside day occupations, taken as a whole. The anthracite industry is equipped with elaborate facilities for preparing the coal for market. The proportion of outside employees used in washing, breaking and sizing the coal is very much greater than any group of workers outside a bituminous mine. Besides, 11 per cent of all outside day workers in anthracite are slate pickers, mainly boys. There is no comparable group of workers around a bituminous-coal mine. If one excludes boy

FIG. 4

Earnings in 1921

Comparing anthracite with bituminous coal in 1921, this diagram shows that proportionately more hard-coal tonnage men make high earnings than do soft-coal workers. The "hump" in the curve between \$1,600 and \$2,000 shows that hard-coal miners make uniformly higher money than soft-coal miners.

FIG. 5

1920-1921

Comparing hard-coal tonnage men in 1921 with soft-coal in 1920, this diagram shows again the high percentage of anthracite workers making the high earnings. Union and non-union bituminous-coal tonnage men range about the same.

employees, and takes all outside workers in anthracite in the year 1921, the average eight-hour days worked per man was about 293. The average earnings was about \$1,320.

In the bituminous-coal industry outside union workers averaged \$1,445 in 207 days; non-union workers averaged about \$1,200 in 218 days. The year 1920 gave more opportunity for employment of daymen. Outside workers averaged \$1,850—\$1,875 for union and \$1,700—\$1,750 for non-union workers. It will be seen that even in 1921 outside daymen made higher earnings in the bituminous coal than in the anthracite industry, and in 1920 the difference was as great as \$400 to \$500. It should be recalled that one is here comparing the year 1920 in bituminous with 1921 in anthracite. The comparison, however, is a fair one, since the year 1920 is only six days above the average operation of the bituminous-coal industry for the last twenty years and the year 1921 was an average one in anthracite. The occupations are, however, widely different.

Earnings of Inside Day Occupations.—Inside day occupations are higher paid than are those for outside employments. The union mines averaged 175 eight-hour days for inside men in 1921 with average earnings of \$1,293. The inside non-union men averaged about 189 days with average earnings of about \$1,125. Inside men in anthracite averaged about 290 eight-hour days with average earnings of \$1,480. It will thus be seen that the inside worker in anthracite made somewhat higher earnings than the inside daymen in either union or non-union bituminous-coal mines, but his working time was 100 days more than either. In 1920 the earnings of inside daymen in the bituminous-coal industry was about \$1,600.

The figures already given for daymen include all short-service men. If full-year employees alone were considered and all inside and outside day employees

grouped, the average earnings in the bituminous-coal industry would be about \$1,850 in 1920 and \$1,570 to \$1,600 in the less regular operation of 1921.

Perhaps the separate occupations can be more easily compared by the average daily earnings of a selected group of well-known occupations. The content of work covered by the same name is not necessarily identical between fields or even within fields and it will be remembered that the opportunity for employment is not the same in the two industries. Yet in so far as any comparison can be made, these are indicative of the earnings of an eight-hour day in the various fields.

Average Daily Earnings in Fifteen Day Occupations in Anthracite and Bituminous

Occupations	Anthracite	Bituminous—	
		Union	Non-union

Laborers.....	4.92	7.16	5.08
Miscellaneous.....	4.96	7.41	5.99

Looked at in a broad way there was in 1921 a surprisingly balanced relation between the average earnings per start by contract miners in the anthracite industry and the tonnage workers in bituminous coal. When the whole year is considered the anthracite miner earned more by reason of more continuous operation; thus relatively about four times as many anthracite workers earned above \$1,200 as bituminous-coal tonnage workers.

The real difference in the industries is found in the earnings of daymen. Here there is a difference in daily earnings of roughly \$1.75 to \$2.25 a day in favor of the bituminous worker. Even with this difference the inside day worker earned about \$200 more in 1921 in anthracite than in bituminous coal by reason of more opportunity to work.

In the case of outside workers the annual earnings as well as the daily earnings were lower in anthracite than in bituminous coal.

In 1921 contract miners in anthracite averaged about \$1,922, making 250 starts; contract miners' laborers in the same working time would earn between \$1,465 and \$1,470. During the same year inside daymen in anthracite had about 40 eight-hour days more opportunity for employment and averaged \$1,475 to \$1,500, while outside daymen by working an average of 3 more days than inside men earned \$160 less. When boys are excluded from this outside computation the yearly earnings of outside men fall from 8 to 8½ per cent lower than those of inside daymen. Judged from the point of view of spending power the contract miners' laborers are in about the same position as the inside daymen in anthracite, owing to the opportunity of the latter for earnings when the mine is idle.

The real problem of earnings in the coal industry is due to the wide fluctuations above and below the average; variations due in part to mining conditions. For this problem attention must be given to the detailed reports published by the U. S. Coal Commission on rates and earnings.

GOVERNOR PREUS, OF MINNESOTA, has been quoted in the press as predicting that public sentiment would force Pennsylvania to bring about some effective regulation of the hard-coal business. Governor Preus believes the State of Pennsylvania should declare coal a public business, as was done with elevators in Minnesota.

Production of Bituminous Coal Producers Classified By Size of Output in 1895, in Net Tons

	Over 500,000	100,000 To 499,999	50,000 To 99,999	10,000 To 49,999	Under 10,000	Total

a From records now available. United States Geological Survey reported 135,118,193 net tons in "Coal in 1895."

From U. S. Coal Commission Report on Engineering and Management.

Advantages of Centrifugal Pump For Coal-Mine Drainage

Recent Developments—Comparing Centrifugal and Reciprocating Pumps on Basis of First Cost and Operating Cost — Economies of Automatic Operation

By GUY V. WOODY

District Manager, Allis-Chalmers Mfg. Co.
Wilkes-Barre, Pa.

IN DETERMINING whether a centrifugal or reciprocating pump should be purchased for a particular pumping condition, a mine operator or his engineers must carefully consider several factors. These factors vary greatly for the different classes of mining. This discussion, however, will apply to the application of the two types of pumps as used in the anthracite mines as there is undoubtedly more water handled per ton of material taken out in the anthracite mining region than in any other. As a rule, also, the water handled has a higher degree of acidity than encountered elsewhere.

Much has been done within the last ten to twelve years in perfecting the centrifugal mine pump for handling acidulous mine water. Along with this development the designer has been able to greatly increase his efficiencies until at the present time there is not the marked difference in that regard which formerly existed between the two types of pumps. Operating efficiencies of 70 per cent at 1,000 g.p.m. and 80 per cent at 3,000 to 4,000 g.p.m. can be obtained with centrifugal mine pumps at the present time. The centrifugal mine pump also has evolved from a fairly complicated piece of machinery with diffusion vanes to a simple unit without diffusion vanes and few moving or wearing parts.

To answer the question under discussion the following approximate figures are interesting:

Type of Pump Material	PUMP DATA	
	Horizontal Duplex Cast Iron, Cement-lined	8 in. 6-Stage Centrifugal Bronze
No. of pumps in station.....	2	2
Capacity of each pump, g.p.m.....	1,500	1,500
Head in feet.....	600	600
Pump efficiency, per cent.....	85	75
Combined efficiency, per cent.....	78	69
Kw. input to driving motor.....	217	246
Kw.-hr. per year for ½-time operation.....	950,000	1,078,000
INITIAL COSTS		
Cost of pumps.....	\$28,000	\$9,000
Cost of motors and control apparatus.....	6,000	5,000
Cost of pumproom.....	8,000	2,500
Cost of foundations.....	500	200
Cost of installing.....	1,200	300
Total initial investment.....	\$43,700	\$17,000
OPERATING COSTS FOR HALF-TIME OPERATION AT 1½c. PER KILOWATT-HOUR		
Interest and depreciation at 15 per cent.....	\$6,560.00	\$2,550.00
Yearly cost of repairs.....	2,400.00	600.00
Yearly cost of labor making repairs.....	1,400.00	200.00
Yearly cost of power.....	14,250.00	16,170.00
Yearly cost of operators.....	5,480.00	5,480.00
	\$30,090.00	\$25,000.00

From the above it is apparent that on the assumption of a power rate of 1½c. per kilowatt-hour and of half-time operation, the centrifugal pumping units undoubtedly should be purchased, as they indicate a saving of approximately \$5,000 per year. We can readily see that as the capacity of units increased for a larger station, with increased efficiency of the centrifugal pumps,

Abstract of Paper presented at the Open Forum of the American Mining Congress Convention held at Milwaukee, Wis., Sept. 24-29, 1923.

FIG. 1—FOUR STAGE BRONZE PUMPING UNIT

A unit is driven by a 225-hp. direct-current motor which pumps against a 350-ft. head.

the operation cost would be even more in favor of the centrifugal pump. The converse of this is true, i.e., as the units grow smaller, the reciprocating type begins to gain in favor until when a point of 750 g.p.m. is reached it is probable that the reciprocating pump, especially at high heads, is the more economical.

The results of the above tabulations would, of course, not show the centrifugal pump so favorable if the power costs were higher and the units operated more hours per year. To show this the following operation costs, based on three-quarter time operation and 2½c. per kilowatt-hour, show that the centrifugal pump is favored by an operation cost of only \$2,235 per year instead of over \$5,000 per year on the first-mentioned basis.

One question has often been brought up when discussing the comparative operation of centrifugal and plunger pumps: "What is the average efficiency of these two types of units over an operating period of five or ten years?" We can answer this only by saying that if both types of pumps are kept in repair and are given the amount of attention that they should have, their relative efficiencies will remain about the same. Many

operators of both types of pump, however, state that the reciprocating pump under moderately high heads increases in slippage and therefore decreases in efficiency faster than the wearing rings on the centrifugal pump reduce the efficiency of this type of pump.

The amount of foreign material in the water as well as the acid content of the water has an important bearing upon the reduction of efficiency, but whether this reduces the efficiency of one type of pump any faster than it does the other type is not evidenced by any data which has come to our attention. We might add that the low heads per stage and extra wide wearing rings, which are now a part of the design of centrifugal mine pumps, have done much to lower the internal leakage and to maintain the efficiency.

OPERATING COSTS FOR THREE-QUARTER TIME OPERATION
AT 2½c. PER KILOWATT-HOUR

Interest and depreciation at 15 per cent	\$6,560.00	\$2,550.00
Yearly cost of repairs	2,400.00	600.00
Yearly cost of labor making repairs	1,400.00	200.00
Yearly power cost	35,600.00	40,395.00
Yearly cost of operators	\$5,480.00	\$5,480.00
	\$51,440.00	\$49,225.00

FIG. 2

Pump For High
Head

This pumping unit is divided into two separate pumps. This usually is done so as to avoid the necessity of unusually large casings.

Another point which many believe is in favor of the centrifugal pump, especially on units having a capacity of 1,000 g.p.m. and more, is their size. This likens a centrifugal pump to the mobile artillery of the army in that it can be quickly moved to places of emergency. This often is important to the mine operator.

For the foregoing reasons it is the opinion of many pump users that each centrifugal pump problem should be figured out on a basis somewhat as mentioned above, taking the actual factors which enter into the particular installation under consideration. In general, however, it would appear that for pumps having a capacity of 1,000 g.p.m. and over, with heads up to 700 or 800 ft., the centrifugal pump would be the more satisfactory type of unit to install. At capacities under 1,000 g.p.m., particularly at the higher heads, one would be inclined to favor the reciprocating type of unit. At the low heads, however, at these smaller capacities, this probably would not hold true and centrifugal pumps could again be economically applied.

A few general rules which should be set down as standardized requirements of centrifugal mine pumps handling acid mine water containing more or less grit or silt, are: (1) All parts coming in contact with the water should be made from a so-called acid-resisting bronze. Two different mixtures of bronze should not be used in the same pump. (2) Low heads per stage should be maintained, these heads approximating 100 ft. In fact, low heads per stage necessitate a design of moderate pump speeds. (3) No dowels, screws or washers should be used on the interior of the pump to hold any parts in place. (4) A type of gasket packing should be used which will prevent acid water from attacking the steel bolts holding together the top and bottom half of the pump casing. Shaft sleeves should be so designed and packed as to prevent water passing through joints and attacking steel shafts. (5) Moving and stationary parts, separate from the pump casing, should be kept to a minimum and all parts should be heavy in section so as to compensate for excessive wear.

Another point which perhaps does not enter into this particular discussion, but which is important, is the automatic priming and operating of all types of pumps. Complete automatic operation of centrifugal pumps has recently been perfected, thereby effecting a saving in the labor cost of pump operators that will amount to something more than \$5,000 per year per station. Smaller size reciprocating pumps have been operated without attendants by automatic starters, the starting and stopping of the pumps being accomplished by float valves. Until recently, however, it was not deemed feasible or even possible to apply automatic starting

FIG. 3—A 10-IN. SIX-STAGE UNIT

This pump has been in operation since 1915 at a mine of the Lehigh Coal & Navigation Co.

and stopping to centrifugal pumps where the sump from which the centrifugal pump took its water was below the level of the pumproom floor. Most of the earlier centrifugal pumps were installed with foot valves on the suction line and were primed by filling the column pipe to a level above that of the top of the pump, thereby making sure that the pump would take its water. These foot valves gave considerable trouble and later steam and air ejectors were used, and at a still later time recourse was had to motor-driven vacuum pumps. Where air is available and where pump operators are on duty the use of an air or steam ejector is a simple and satisfactory method for priming.

Due to certain labor conditions, in the anthracite field particularly, it is necessary that the pump operators work in three shifts. This increases the cost of this class of labor to a considerable amount and since "necessity is the mother of invention," a new scheme has been developed and put into use on centrifugal pumps which makes it possible to dispense entirely with the pump operator.

The operation of the automatic centrifugal pumping outfit is as follows: A motor-driven vacuum pump controlled by a float switch in the sump is used for priming the centrifugal pump. Vacuum regulators, pressure regulators and bearing thermostats are used and connected in such a manner as to give ample protection to the pump and motor. The motor is protected against hot bearings, excessive overloads, failure of power and the pump against excessive suction lifts, air leaks, lack of priming or broken discharge lines.

FIG. 4

Heavy Duty Pumping Unit

Where the water is very acidulous and gritty the pumping head per stage usually is less than 100 ft. This pump is used on an 800-ft. lift.

Proud of Their Product Welsh Operators Sell on Reputation

With Few Exceptions, Scrupulous
Attention Is Given to Quality of All
Shipments—Radical Labor Element
in Evidence—Overwhelming Senti-
ment for Nationalization of Mines

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

BECAUSE of its quality, there never has been a time when Welsh coal has been a drug on the market. There have been many times when it has been sold at a loss, but the price never has gone so low that the loss would not have been greater were production to have been suspended entirely. The operators in the Welsh field believe they have the best coal in the world, and they have sold that idea to a large number of buyers in many countries. The coal of southern West Virginia is the only product which they will admit approximates the value of their own. Their trade names have become widely known. In their foresighted way of preserving the reputation of these coals, the collieries which have built up the reputation of these names pay scrupulous attention to the quality of all shipments.

There are, of course, some unscrupulous shippers in Wales who take advantage of any emergency to forward dirty or poor-quality coal. This practice, however, has brought about a bitter feeling against such shippers, who by their action injure the reputation of all coal from Wales.

As a result of the abnormal situations which have occurred and recurred since the beginning of the war, a considerable number of irresponsible speculators have fastened themselves on the British coal industry. They are the source of great annoyance to the responsible and established companies. They frequently make lower bids than the market justifies, in order to get business. They think nothing of failure to deliver if they cannot get the coal, and as they have little or no financial responsibility, the foreign purchaser has no redress. The effect, however, is to injure the reputation of the field generally and to inflict serious losses on responsible coal concerns, since they are forced at times to meet prices being quoted by the "fly-by-nights."

RADICAL ELEMENT NUMEROUS IN SOUTH WALES

Labor in south Wales is regarded as being much more radical than in any other of the thirteen coal-producing districts in the British Isles. This in turn calls forth a more radical counter-policy, so that the operators in that section are reputed to be less conciliatory than in other fields. Even in south Wales, however, the union is highly conservative as compared with many of the district organizations of the United Mine Workers of America. To this generalization at least one exception must be made. British labor overwhelmingly favors nationalization of the coal mines. Frank Hodges, secretary of the miners' federation of south Wales, is highly educated, and, as is said over there, has "letters after his name." His ability is recognized universally, as is that of most of the labor leaders, district and national. As in America, the leaders among the operators are no match for those who have come to the top among the workers.

In that connection it may be mentioned that the union in Great Britain feels that it has a very sympathetic friend in John L. Lewis, who is much admired by labor in the British fields. "Why shouldn't he be friendly to labor over here?" one man said to me. "He has a good British name: 'L' for London; 'e' for England; 'w' for Wales; 'i' for Ireland, and 's' for Scotland."

As in America, the conservative leaders have difficulty in keeping the rank and file from plunging blindly after some radical agitator. They are somewhat like a certain shepherd, to use an example cited to me on the floor at the coal exchange at Cardiff. This shepherd was taking his flock across a swift channel on a ferryboat. He stooped over to tie his shoe and was butted heavily by the flock's ram. This so angered the burly shepherd that he grabbed the ram by the horns and threw him overboard. No sooner had the ram hit the water than the flock began to follow. Most of the sheep were lost before the remainder could be prevented from following their leader.

In certain instances, labor in Great Britain has shown just as little judgment in following certain self-constituted leaders, but, being Anglo-Saxons, the tendency to do unsound things is nothing like so marked as is the case in the United States. The conservative leaders have their men much better in hand and do not have to resort to as much demagoguery as do the conservative labor leaders in America.

MUCH OF MINE TIMBER IS IMPORTED

Labor in the Welsh field lost heavily this year because of a series of foolish strikes, much like strikes in our building trades over jurisdictional awards. There was no quarrel between the men and the operators, but the Miners' Federation and Craftsmen's unions staged a bitter conflict. This stopped production just at a time when coal prices were high and, in addition, ran up the cost of operation so that the men lost heavily in wages and diminished the profits in which they share. There never has been a strike in south Wales during which the men abandoned the pumps. Such action would cause incalculable harm in mines of such great depth and in a formation which is hard to hold at best. Extensive timbering must be done. Most of the props must be imported. France and Finland have been the chief sources of supply but now Nova Scotia is supplying a material part of the requirements.

As a consequence, props are very expensive, but the expenditure for them has been greatly reduced under the profit-sharing wage. This item is cited by operators as one of the best examples of the benefits following a real interest on the part of the workers in the profits of the operation.

Next week Mr. Wooton will describe how the British wage agreement of 1920 worked.

The Miner's Torch

The Mine Foreman: An Imaginary Book Review

NO SUPERINTENDENT can read this book without saying to himself, "I wish I had a foreman like that fellow; I'd be able to leave the job once in a while and really enjoy myself." Time was when the average foreman took entire responsibility for the inside of the mine just as the man we have been reading about, but somehow we don't find many that can measure up to that standard now. Those who do, get promoted to superintendent's jobs very quickly just as the hero of the story did, but they don't have to trust to luck nor save the manager's daughter from a mob to get there.

Even though we don't run across such animals every day it's interesting to read about them. The description of his encounter with two dissatisfied miners in different sections of the mine who were made happy on promises of new places as soon as possible and then simply allowed to remain idle a few days and change places with one another unawares is almost too ridiculous to be true, and yet we can all recall mine foremen diplomatic enough to pull such stunts successfully.

It's almost possible to look at a map of the workings of any mine and tell whether the foreman in charge is of that type because it takes such a foreman to get all of the rooms worked and to keep all of the headings driving. I have been furnished with many a laugh listening to foremen trying to explain why blocks of coal had to be left on certain headings in their section of the mine and then getting them to compare notes with other foremen who were able to control their miners so that no blocks of coal *had* to be left.

Perhaps if the mine foremen who are able to get all of their rooms worked could expect some special recognition because they have helped to conserve our natural resources, the figures used as representing the average recovery in tons per foot acre for different localities might be revised upward considerably.

The author does not suggest that his mine foreman could have been happier nor would his services to his company have been more valuable could he have looked forward to special recognition or larger rewards, but we must remember that he was interested only in giving us the picture of a mine foreman appearing as the hero of a romance, and a discussion of motives and rewards has no place in romantic writing.

The author of the book does show convincingly, however, that the life of the average mine foreman can be used as narrative matter furnishing interesting reading, but as I finished the book I found myself wondering if the life of a mine foreman holds much of interest to the man who is actually living the life and if not, who worries about it. At any rate the book put me to thinking and any book that puts people to thinking deserves to be passed on to our friends.

This space will be occupied by the author of "Extracts from a Superintendent's Diary," which ran in "Coal Age," June 20, 1914, to Aug. 26, 1916.

Mine Institute Discusses Coal Baking and Slope Belts

Education, Compensation and Administration Also Considered—Devolatilized Coal as Substitute for Anthracite—Short Shafts Not Justifiable

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*, Pittsburgh, Pa.

SLACK will be moved in a slow market by converting it into carbocite and selling that product in competition with anthracite, provided the plans of a large company in Illinois producing 5,000 tons of slack daily reach entire fruition, said R. D. Lamie, of Huntington, W. Va., in discussing low-temperature distillation at the meeting of the West Virginia Coal Mining Institute, held at Huntington, Dec. 4 and 5.

Mr. Lamie supplemented in his remarks the paper delivered in Clarksburg to the same organization June 13 and published in *Coal Age* Aug. 2, p. 171. After reviewing other processes of low-temperature distillation Mr. Lamie declared that carbocite seems destined to compete with domestic sizes of anthracite.

Asked by W. E. Fohl and Thomas F. Downing, Jr., whether coal of inferior quality could be satisfactorily used in the carbocite process, Mr. Lamie replied that coal that did not coke is better suited for low-temperature distillation, because gas escapes more readily from it as a result of its non-fluxing property.

Mr. Fohl had in mind coal from the Freeport seam and Mr. Downing bony coal. In reply, therefore, to the latter, Mr. Lamie declared that bony coal was of value for its volatile constituents but that these were not worth the cost of erecting a carbocite plant. He added that the cost of the plant would be greater for the same return in byproducts owing to the presence of the ash in the coal and declared that a 200-ton plant for carbonizing bone coal would cost as much as a 500-ton plant for the carbonization of good coal.

CLASSES BONE COAL WITH OIL SHALE

He recommended that inquiries be made into other methods of recovering gas from bony coal. The residue of bone coal, like that from oil shale, is valueless, for which reason the development of the oil-shale industry will be set back many years, especially if high-volatile coals, so much better suited to low-temperature distillation, are extensively subjected to that process and thus adequately supply the market. Carbocite, weight for weight, said Mr. Lamie, is worth as much as the coal from which it is derived, and then beyond that there is the value of the byproducts distilled from it.

Carbocite, if it is to be used for large steam-plant purposes, undoubtedly should be pulverized and fed into the boiler furnace in the same manner as raw pulverized coal. It can be made into briquets, the process adding \$1.50 a ton to its cost. Mr. Lamie was not ready to say whether carbocite would compete satisfactorily with oil for steam purposes. Oil is purchased cheaply along the Atlantic and Pacific coasts and in the Southwest but is more expensive in the Middle West.

Adam Crawford in a paper discussed "Safety Organization and Administration," which served to introduce the problem of what should be done with the surplus in the State Compensation Fund.

Mr. Crawford is of the opinion that a portion of the fund should be devoted to the education of miners in

extension schools. Dr. J. J. Rutledge, chief mining engineer of the Maryland Bureau of Mines, thought favorably of the suggestion, for there is no other convenient way of raising money for this purpose. Colonel Downing objected emphatically on the ground that the fund could be used more profitably for the lowering of insurance rates. Diplomatically, Walter Cunningham, of Charleston, smoothed matters by saying, "Let the surplus fund grow." Later the Compensation Commission of the state can lower rates or lend a portion of it to mine owners who are willing to use it for bettering safety conditions at the time; or better still, it can be used for educating miners, thereby increasing their efficiency and decreasing accidents.

It devolved upon R. F. Carson, consulting engineer, of Huntington, to fill the chair of President A. C. Callen, who could not attend because of illness in his family. The chairman, consequently, read the president's address. Because of the meager attendance at the beginning of the morning session, C. B. Snow, president of the Huntington Chamber of Commerce delayed his address of welcome till the opening of the afternoon session, when an address on "The Limitations and Eccentricities of the Beckley Seam" was delivered by C. R. Stahl, who is assistant general manager of the E. E. White Coal Co. of Stotesbury, W. Va. No one present was sufficiently conversant with the Beckley seam to undertake to discuss this paper.

NO JUSTIFICATION FOR A SHALLOW SHAFT

The institute then turned its attention to a paper on "Belt Conveyors and Their Applications for Hoisting from Shallow Seams," presented by Alphonse F. Brosky, assistant editor of *Coal Age*. J. H. Edwards, electrical engineer of the Elkhorn Piney Coal Co., substantiated the statements in the paper relating to the power consumed in hoisting by a slope conveyor. He wondered why a shaft and not a slope was sunk in the shallow cover of a certain Logan County mine, which is 90 ft. deep. From it a 250-hp. hoist raises daily in cages about 1,100 tons of coal. At another mine of the same company, three-quarters of a mile away, where the conditions are exactly the same as at the shaft mine and the same tonnage is produced, a 25-deg. pan conveyor is operating, driven by a 75-hp. motor. Because both these mines are metered the company is in a position to compare relative power consumptions. The shaft mine consumes 1 kw.-hr. in hoisting $3\frac{1}{2}$ tons of coal and the slope mine for the same expenditure of energy hoists $4\frac{1}{2}$ tons, a saving of 22 per cent in power at the slope mine.

William Venable said that a scraper conveyor sometimes is better suited for hoisting purposes than a belt conveyor. Mr. Brosky remarked in reply that the friction between the moving parts and the coal on the pan of the conveyor militated against the efficiency of such equipment. Mr. Venable added that a scraper conveyor was preferable where the distance the coal had to be lifted was short and the slope was steep. As the friction depended on the cosine of the angle of slope, the steep scraper conveyor operated with minimum friction. He referred to an installation in a coal storage yard at Charleston which required only a small motor to lift the coal to a height of about 70 ft., the conveyor in that plant being short and steep. Mr. Brosky related the experiences of the Valley Camp Coal Co. at its No. 1 mine, near Pittsburgh, Pa. There a scraper conveyor is used for hoisting coal up a slope. The company finds that this conveyor is less efficient

than the pan conveyor installed at its Kinloch mine. Seeing that the latter approaches most nearly to the belt conveyor of all those made of metal the efficiency of conveyance by belts is suggested if not proved.

When asked by Mr. Fohl how the cost of slope equipment compares with that of shaft equipment at a proposed mine of the Hudson Coal Co. near Morgantown, Mr. Brosky said that the former figured considerably less than shaft equipment, though the cost of sinking favored the shaft. However, the advantages derived by the use of a slope would give it preference even if the total first cost were more. The proposed mine is to yield 4,000 tons of coal per day from the Sewickley seam which lies at a depth of 275 ft. The slope was chosen in preference to a shaft with 10-ton skips.

TRAVELS 95 MILES TO MINING SCHOOL

In a paper on "Progress of Extension Schools in Mining Communities of Maryland," Dr. Rutledge noted the eagerness with which miners attend classes and the hardships they sometimes endure in so doing. One man travels 95 miles once a week to attend night school, stays over night and returns the following day. His attendance has been 100 per cent since the extension courses were started. When Dr. Rutledge claimed the record for the largest weekly attendance at an extension class in the country, Mr. Crawford, of West Virginia University, claimed a superior record in a single attendance of 104 at a class in Kilsythe, W. Va.

R. J. Stanton, president of the mining institute of the Logan County Coal Corporation at Lundale, W. Va., described the meetings of his organization and the benefits derived from it. All those who desire to learn, from the president of the corporation down to the miner, are admitted to the classes and join freely in discussions of problems arising at the mines of the corporation. Papers are prepared and delivered by various members and outsiders. Prominent speakers often are obtained. He said that F. R. Wadleigh, formerly Federal Fuel Distributor of Washington, D. C., would speak to this institute on Dec. 8. Money shares are sold to the members on a time-payment basis at the rate of five dollars per share per month. The money is invested in secure bonds which pay 6 to 7 per cent interest. This is distributed to the accounts of holders of shares. The institute buys one \$1,000 bond each month, from 200 payments of \$5 each.

"Training Future Coal-Mine Executives" tied technical with practical training and showed how the combination can best be obtained. This paper was delivered by Charles E. Lawall, assistant professor of mine engineering at West Virginia University.

Dean E. A. Holbrook, of Pennsylvania State College, read a paper on "Mine Safety Conditions in the United States," which summarized the work of his committee in investigating this phase of mine operation for the Coal Commission.

The concluding paper was "Factors in Management," by Bill McCoy, of Pittsburgh, who pointed out three requisites for successful management, namely, competency, executive ability and personality. His paper dealt chiefly with the psychology of management.

Institute officers and committees for the ensuing year are: President, J. W. Reed, of Fairmont; Vice Presidents, Thomas F. Downing, Jr., C. C. Morfit, J. R. Cameron, P. C. Thomas and W. H. Cunningham; executive committee, Frank Haas, W. E. Fohl, R. M. Lambie and Edward Knight; Secretary-Treasurer, R. E. Sherwood.

Pinchot Proposes Anthracite Control By Federal Commission

Explains Contemplated Measure to "Progressive" Senators—Borah
Evinces Deep Interest—After Lengthy Conference with the
Governor Senator Pepper Approves Measure

Governor Pinchot, of Pennsylvania, has outlined a bill providing for federal regulation of the anthracite industry through a coal division of the Interstate Commerce Commission. The Governor spent last Friday in Washington explaining the proposed measure to "progressive" Senators, asking them to study it and lend their support with whatever changes may be necessary to increase its effectiveness. Senator Borah seemed especially interested in the bill and expects to introduce it, but with considerable modification.

On his return to Harrisburg, Friday evening, the Governor mailed a synopsis of the measure to the governors of thirty anthracite-consuming states. The proposed Coal Division would work in co-operation with the

police powers of the anthracite-consuming states, which would be pooled according to the provisions of the proposed compact of states, a draft of which Governor Pinchot has already sent to the other Governors. Those two measures combined form the Pinchot plan, which will form the basis of the discussion at the second of the coal conferences to be held at Harrisburg Dec. 13 by the representatives of the states interested.

The Coal Division, as proposed, would consist of three members to be appointed by the President, not more than two of whom should be of the same political party. Each commissioner would receive \$10,000 a year and his term would be for seven years.

Governor Pinchot and Senator Pep-

per of Pennsylvania held a protracted conference on Saturday in the latter's office going over the whole situation involved in the governor's proposed bill. After the conference it was announced from Senator Pepper's office that the Senator would be willing to introduce the bill, that he approved of it in a general way and that he would at least sponsor legislation along the general lines of the proposed bill. It was also stated, however, that nothing would be done until the conference of Governors, called for Dec. 13, is held.

Nine Men Killed by Explosion In Wet, Non-Gaseous Mine

An explosion, thought to have been caused by coal dust, occurred at 4:45 p.m., Dec. 7, 700 ft. from the mouth of the Blackhawk Coal Co.'s mine at Happy, Carr's Fork, Perry County, in the Hazard field of eastern Kentucky. It resulted in the death of seven men and in injuring six, two of the injured dying later and the other four being reported in a serious condition.

A report from Hazard, Ky., stated that there were but thirteen men in the mine, which employs about 100 workers. The rest of the crew had quit for the day promptly at 4 p.m. A faulty or windy shot is believed to have ignited the dust, although it will be difficult to determine the actual cause, as most of those who might know what happened are dead or seriously injured.

The mine is wet as compared with others in the same region, only a small portion of the workings being dry. This makes it difficult to understand how the accident occurred. So far as known it is the first severe explosion the Hazard field has ever experienced, for the coal measures are not gassy. There have been a few men injured or killed from time to time from faulty shots, but the mine officials in general believe that the mines are too dry to be subject to dust explosions.

Reports from Hazard state that the force of the explosion wrecked the office located at the mouth of the mine and, according to some reports, stopped the fans, but it is not clear that they were running when the explosion occurred. John Lewis, Foreman Mullins and others on the outside of the mine quickly formed a rescue party, started the fans and followed fresh air into the mine, finding seven men dead on the floor near one another. Death apparently was instantaneous. The six injured were found near the group of dead.

The mine is a comparatively new one. It was formerly known as the Perciful Gorman Coal Co. and was reorganized about a year ago as the Black Hawk Coal Co. at a time when Kenneth U. Meguire, of the Harlan Coal Co., Louisville, and associates became interested in it. Mr. Meguire is president, and he and Gorman are the principal owners. Mr. Gorman is an experienced mine manager, and some years ago led the rescue party in a bad Tennessee mine disaster.

Pinchot Outlines Anthracite-Regulation Measure

In a statement issued Dec. 7 Governor Pinchot said that the bill to regulate the anthracite industry should embody these provisions:

1. (a) *It should provide for the broadest possible control of anthracite in interstate commerce by a federal commission.*

(b) *Such a commission should probably be constituted a coal division of the Interstate Commerce Commission, composed of three members.*

(c) *The coal division should act not as an administrative court but as a board proceeding upon its own initiative to investigate and regulate the industry.*

(d) *The Coal Division should serve with the Interstate Commerce Commission when coal transportation rates, distribution of coal cars or regulations of carriers affecting the coal industry are under consideration, but otherwise have no jurisdiction over carriers' rates.*

(e) *The Interstate Commerce Commission should have no jurisdiction to review an order or recommendation of the Coal Division.*

2. *The act should declare it unlawful for those engaged in the production and distribution of anthracite in interstate commerce to use unfair practices, to charge unreasonable prices, to create monopolies in or restrain interstate commerce in coal, or to engage in any practice, not in interstate commerce, which causes any unreasonable discrimination against interstate commerce in coal.*

3. *The act should give the Coal Division the broadest possible powers:*

(a) *To investigate and publish the facts in relation to anthracite coal affecting interstate commerce.*

(b) *To make recommendations on any subject connected with the anthracite industry.*

4. (a) *The act should authorize the Coal Division to issue mandatory orders for compliance with its recommendations when the public interest requires.*

(b) *Such orders should be issued only after opportunity for a hearing.*

(c) *Mandatory orders as to wages or conditions of employment should be prohibited.*

(d) *In order to meet constitutional objections the right to fight the price of coal, etc., by mandatory order should be limited to cases where, in the absence of regulation, there exist, or is danger of exorbitant charges and arbitrary control.*

5. (a) *Provision should be made for appeals from orders of the Coal Division to the U. S. Circuit Courts of Appeals, as in the case of appeals from the Federal Trade Commission.*

(b) *Orders unappealed from or affirmed on appeal should be final. They should be enforceable by injunction and through the imposition of penalties.*

6. *Penalties should be provided similar to those in the Packers and Stockyards act of 1921.*

President Coolidge's Recommendations on Coal In First Message to Congress

The cost of coal has become unbearably high. It places a great burden on our industrial and domestic life. The public welfare requires a reduction in the price of fuel. With the enormous deposits in existence, failure of supply ought not to be tolerated. Those responsible for the conditions in this industry should undertake its reform and free it from any charge of profiteering.

The report of the Coal Commission will be before the Congress. It comprises all the facts. It represents the mature deliberations and conclusions of the best talent and experience that ever made a national survey of the production and distribution of fuel. I do not favor Government ownership or operation of coal mines. The need is for action under private ownership that will secure greater continuity of production and greater public protection. The Federal Government probably has no peace-time authority to regulate wages, prices, or profits in coal at the mines or among dealers, but by ascertaining and publishing facts it can exercise great influence.

The source of the difficulty in the bituminous coal fields is the intermittence of operation which causes great waste of both capital and labor. That part of the report dealing with this problem has much significance, and is suggestive of necessary

remedies. By amending the car rules, by encouraging greater unity of ownership, and possibly by permitting common selling agents for limited districts on condition that they accept adequate regulations and guarantee that competition between districts be unlimited, distribution, storage, and continuity ought to be improved.

The supply of coal must be constant. In case of its prospective interruption, the President should have authority to appoint a commission empowered to deal with whatever emergency situation might arise, to aid conciliation and voluntary arbitration, to adjust any existing or threatened controversy between the employer and the employee when collective bargaining fails, and by controlling distribution to prevent profiteering in this vital necessity. This legislation is exceedingly urgent, and essential to the exercise of national authority for the protection of the people. Those who undertake the responsibility of management or employment in this industry do so with the full knowledge that the public interest is paramount, and that to fail through any motive of selfishness in its service is such a betrayal of duty as warrants uncompromising action by the Government.

Does Coolidge Message Mean Regulation, Fact Finding or Voluntary Returns?

Coal Sections Considered Vague—President Doubtful Whether Government Has Power to Fix Prices, Wages and Profits Except in Extreme Emergency—Coal Not to Be Major Issue

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

In so far as it deals with coal, the President's message is ambiguous. It gives the impression that he is not in favor of regulation except during extreme emergency, but there appears to be great difference of opinion as to the significance of what he said. It indicates that he is doubtful whether the federal government has any power to fix prices, wages or profits, or take similar action in peace times. He does make the clear-cut statement that he does not believe in government ownership. This statement could have been little more than a gesture, since hardly anyone believes in it, and certainly there had been no doubt as to Mr. Coolidge's position.

The message has failed to clear the air. So far as coal is concerned, a state of doubt, of hesitancy and of expectation has existed for three months. There have been rumors of drastic federal action. Then came Governor Pinchot's plan for drastic regulation through the states. In addition there were the pending recommendations of the Harding Coal Commission providing a mild form of regulation. Only a few days ago Senator Smoot, one of the mainsprings of the majority party, pointed to the Coal Commission's findings as justification for his belief that large profits are enjoyed by the coal industry. Some took it to indicate that justification was being provided for an administration effort to bring about regulation.

Within the coal industry there have been two views as to the best plan of procedure. Some, convinced that a storm is coming, urged that a point be conceded and that voluntary returns be made in the hope that this would head off something even less desirable. The other view was to surrender

nothing and be ready to take issue with the federal government at any time so as to determine once for all the exact extent of federal authority.

In such a situation as this it had been hoped that some of the uncertainty, at least, would be removed by the presidential message. Through the mist which surrounds the President's utterance on coal one can discern certain familiar forms, such as intermittency, storage and car rules, but the label on the exhibit cannot be made out, so it still is uncertain whether they spell regulation, compulsory fact finding, or voluntary returns.

There is one very certain deduction that can be made. That is that the administration is not disposed to make coal a major issue. The message certainly strengthens the position of those within the industry who are opposing voluntary reporting. There can be no doubt that the principal pressure in favor of voluntary reports has come from the fear that it was either that or something worse. Now that pressure is much relieved.

It is apparent that the President is not disposed to make a great fight that would have as its object the regulation of the coal industry. Without his influence, those who may have in mind some such plan are certain to recognize that any chance they may have had for success has been weakened greatly. It is known, however, that legislation will be introduced covering all recommendations of the Coal Commission. It is believed that the President would approve of such a measure, but in view of this message, he evidently is of the opinion that Congress has the facts and can decide for itself whether or not legislation presents the best method of dealing with the situation in coal. In this connection, it is of interest that Secretary Hoover, on the day preceding the delivery of the President's message to Congress, indicated in a public address that he had no great faith in the effectiveness of coal legislation at this time.

Three Drown When Water Floods Illinois Mine

The spectacular flooding of the Radium mine of the Aluminum Ore Co. of America, at Belleville, Ill., drowned three men Dec. 6 and gave most of the other 250 men in the mine a race for their lives. The water broke into the mine when an entry was driven too close to an adjoining water-filled, abandoned working. The face broke through and the water rushed in together with a considerable volume of gas. Louis Ambruster, William Lescher and John Evans, all of Belleville, were drowned. Six others were gassed but were carried out and have recovered. Herman Isler, a foreman, won public praise by holding open a door on No. 5 entry in which the break occurred, until all the forty-eight men in that entry except the three, were out.

Midwest Operators Favorably Impressed With Coolidge Message on Coal

Recommendations to Reduce Overhead Costs Strike Responsive Chord—
Continuity of Operation the Paramount Object—Self-Reform
Favored—Removal of Sherman Law Restrictions Necessary

Middle Western coal operators who do a good deal of the thinking for their sections of the industry are ready to admit, almost to a man, that the President's message on coal was an honest and from-the-shoulder document. It said about all a President could be expected to say, with the information that he has at hand. It is evident from their statements to *Coal Age*, however, that they are not looking to President Coolidge for any Moses-like leadership from the coal wilderness.

Dr. F. C. Honnold, of the Honnold Coal Bureau, Chicago, said: "It is notable that the President favors 'greater unity of ownership' and the establishment of common selling agencies, both of which seem to promise some reduction in overhead costs, both in administration of mines and in sales cost. Nothing, however, according to his apparent conviction, even approximates the importance of the continuity of mine operation and the removal of recurrent strikes. And in this particular his viewpoint meets exactly the ideas of the coal-mine operators, but of late years no way has been found to prevent the mine workers' union from ordering discontinuance of work if and when the demands of union leaders were not met.

"It is evident that the President is still hopeful and believes that a commission appointed and properly empowered by the government would be able to conciliate and obtain voluntary arbitration and to adjust any threatened controversy between mine owners and their employees. It is extremely difficult for the operators to understand how such a hope can be justified upon the basis of the experience of the last three years.

"The President's remark that the failure of either management or employees to recognize the public interest or to fail, through any motive of selfishness, to render service constitutes a betrayal of duty and warrants uncompromising action by the government, seems in view of experience, to be a rather vague declaration."

J. B. Pauley, vice-president and general manager of the J. K. Dering Coal Co., Chicago, said: "The President's message is unique and refreshing. It bears the stamp of an honest statement by an honest man, without consideration of political features or personal effect. With that portion which refers specifically to the coal industry there is little opportunity for disagreement, generally speaking.

"The facts about coal are well known. The remedies are not so simple. Many intelligent coal operators, who have spent a life time in the business, would

find it difficult to prescribe such remedies; hence the President could not be expected to do it, knowing the main facts as he does. The laws and Constitution would prevent the application of the natural remedies which would occur to the President, or anyone else, in attempting to solve this complicated problem, but in spite of all this, the message, as it refers to coal, carries a constructive undertone.

"The statement that 'those responsible for the conditions in the industry should undertake its reform' is encouraging and salvation could probably be worked out along these lines, with proper encouragement from the government, without any great prejudice to those involved, if it were possible to eliminate consideration of the political effect, which, unfortunately, is usually held to be of paramount importance."

W. K. Kavanaugh, president of the Southern Coal, Coke & Mining Co., St. Louis, thinks "the President's message is all right, considering the light he has upon the subject. I was particularly interested in his reference to necessary remedies which would encourage greater unity of ownership. The need for conservation in this great basic industry should be made clear to Congress so that possibly it might see the importance of removing the Sherman anti-trust law restrictions as applied to coal."

Dr. C. H. Krause, St. Louis, president of the Fifth and Ninth Districts Coal Operators' Association, declares: "Coal men in Illinois realize and recognize their responsibility to the public as producers of one of the essential commodities; also their responsibility as employers of a large body of American citizens. They see in the President's message an understanding and official recognition of the community of interest between the various elements of industry and a disposition to fairness that should result in the coal industry's working out its own problems equitably."

According to W. L. A. Johnson, Kansas City, commissioner of the Southwest Interstate Coal Operator's Association, "the President's message on coal is a clean-cut, logical statement on the proper solution of the present deplorable condition of the coal industry. If it is crystalized into unbiased legislation in the interest of all factors concerned, it should go far to remedy many existing evils. Operators generally will co-operate with Congress to obtain proper legislation but will resist partisan or unfair legislation that seeks to stifle private enterprise or free and untrammelled management of industry within the limits of constitutional law."

State Treasurer Would Abolish Anthracite Tax

Charles A. Snyder, State Treasurer of Pennsylvania, issued a statement last week relative to the collections for the year ending Nov. 30, 1923, during which period \$64,200,917.44 was received. This sum was \$8,000,000 in excess of the moneys collected for the fiscal year ending Nov. 30, 1922.

Because of this increase, the Treasurer pointed out there is no necessity for the continuance of the anthracite tax or the net profits tax laws on the statutes. The sum of \$62,000,000 of that collected, he said, came from old revenue-producing laws passed prior to 1917, and these laws, if the Auditor General is given additional powers, can produce \$65,000,000 or more a year.

"The State Treasurer contends," the statement read, "that the profits tax and the coal tax should be abolished at the next session of the Legislature, and added powers given to the Auditor General for the closer inspection and investigation of taxes due under old laws."

Rail Coal Consumption Falls Slightly in September

Class 1 railroads of the United States consumed 8,521,000 net tons of coal during September, 1923, as charged to account 394, compared with 8,529,000 tons in the preceding month and 7,856,000 in September, 1922, according to a report by the Bureau of Statistics of the Interstate Commerce Commission covering 176 steam roads. During the first nine months of 1923 these roads consumed 82,299,000 tons as compared with 51,736,000 tons in the corresponding period of 1922. The delivered cost per ton in September last was \$3.31; in September, 1922, it was \$4.83.

Consumption of fuel oil during September was 175,943,000 gallons, compared with 168,868,000 gallons in August and 138,232,000 gallons in September, 1922.

Coal Legislation Hopper

Representative Rogers, of Massachusetts, has introduced a bill in Congress which provides that whenever the President shall find that the public interest requires it, he is authorized to declare an embargo on the exportation of coal to foreign countries, such order to include either anthracite or bituminous coal or both.

Senator Borah, of Idaho, is working on two coal bills, as a result of an exhaustive study of the Coal Commission's reports and recommendations.

A bill setting standards of preparation for domestic coal has been introduced in the House by Representative Luce, of Massachusetts. The bill requires certificates attached to bills of lading declaring that shipments conform to one of the standards provided for. Penalties are provided for making false statements.

It is understood that the LaFollette "radical" bloc is considering some coal legislation but is not yet prepared to announce its purpose.

Union Organizing Under Cover Puzzles Harlan and Hazard Fields

Sudden Walkout When Notice of Proposed Wage Cut Is Posted
Causes Speculation on Extent of Union Influx—
Operators Receive Mysterious Letters

How great has been the infiltration of United Mine Workers into the open-shop mines of the Harlan fields of southeastern Kentucky? That is the big question that has been disturbing Kentucky coal circles in the neighborhood of Cincinnati during the past week or ten days.

Keyed in with this is the problem of whether the mines having a union agreement will attempt to throw this off. On Nov. 10 the officers of District 19 of the United Mine Workers named Nov. 26 and Harlan Ky., as the date and place of a meeting to work out an agreement for the Harlan field. No notice was served on the union people. On Dec. 5 a letter was directed to R. C. Tway, president of the Harlan Coal Operators' Association, in which the statement is made: "Common courtesy warrants you to at least answer our communication. . . . We say to you that any industrial conflict that may take place in the Harlan coal field you, gentlemen, will be directly responsible for." Those interested in Harlan operations with offices here in discussing

the situation, say that it remains *in statu quo*.

The extent of the influx of unionists into open-shop mines was shown in a peculiar manner last week. Facing losses through low prices a large operator posted notice of a 20 per cent horizontal cut in wages. The next day all of the men flashed union buttons on him—and walked out. He had no reason to suppose that his mine had been "organized."

Evidence of further trouble comes from a mysterious hand-written letter posted on a Louisville & Nashville train and addressed to several operating companies with headquarters in Cincinnati as well as to operating headquarters in the Hazard fields, in which it was stated that "it would be best for all of the Hazard mines to close until Jan. 1 and avoid trouble."

General earmarks such as these would indicate that the southeastern fields are in a foment such as they went through when the last effort to implant unionism was made there four or five years ago.

William L. Connell Dies

William L. Connell, member of the Anthracite Board of Conciliation since its organization in 1902, and one of the prominent hard-coal operators, died at his home in Scranton, Dec. 10. He was born in Minooka, Pa., Oct. 14, 1862. Mr. Connell, who was twice Mayor of Scranton, returned to business last spring after a seven months' illness apparently in good health and attended a meeting of the Conciliation Board on Dec. 7, when the Hudson Coal Co. situation was under consideration.

In 1891 he organized and managed the Enterprise Coal Co., which has been in operation since and which has its mines near Shamokin, Pa. Later he became president and general manager of the Green Ridge Coal Co., and later he headed the Connell Anthracite Mining Co. and the Lackawanna Coal &

WILLIAM L. CONNELL

Cave-in at Jessup, Pa., Traps Five; All Believed Dead

Five men, including Evan Jones, the mine foreman, are crushed to death or entombed in the Mount Jessup mine of the Mount Jessup Coal Co., Jessup, Pa., as a result of cave which occurred Dec. 8. All efforts to get into communication with the men have failed and virtually all hope of finding them alive has been abandoned by the rescuers.

Mine Foreman Jones lost his life in trying to save the lives of his workmen, according to the stories told by some of the workmen who escaped death. He had gone into the mine to inspect some work, when he thought he heard the sound of sliding rock and began ordering workmen outside. He told the retreating miners that he was going to other sections of the vein to warn four other workmen, and despite their protests, went. At about the time the mine foreman would have reached the part in which the four men were working the roof collapsed. Hope was entertained for a time that Jones and the four men had escaped by way of the Sterrick Creek shaft.

Gangs of workmen under the direction of mine inspectors and officials are working in relays to remove the debris from the area affected, which is about 150 ft. square.

Two of the missing men are said to have been engaged in the work of robbing pillars when the cave occurred.

Mechanical Engineers Study Coal Storage

Coal-storage problems were discussed at the session of the Material Handling Division of the American Society of Mechanical Engineers, which held its annual meeting in New York City from Dec. 3 to Dec. 6, the morning of Dec. 5 being devoted to these problems.

In describing various coal-storage systems, H. E. Birch and H. V. Coe stated that the amount of coal in storage depends on the distance from source of supply, adequacy of rail and water connections, the seriousness of a possible shutdown, the probable future growth of the plant, and other local considerations which must be weighed separately for the plant in question.

In his paper on "Factors in the Spontaneous Combustion of Coal," O. P. Hood, chief mechanical engineer, U. S. Bureau of Mines, said that in order that the engineer may intelligently consider the phenomena of spontaneous combustion of coal he must have some general ideas about the coal substance, the character of coal surface, the atmosphere in which it may be immersed and about slow combustion.

A paper on "Economic Phases of Coal Storage," by F. C. Tryon and W. F. McKenney, of the Geological Survey, embodied the results of a study made by the coal-storage committee of the Federated American Engineering Societies pointing to the economic advantages of coal storage.

Lumber Co. During his service as a member of the Board of Conciliation Mr. Connell was the representative of the independent operators.

His part as a leader in the anthracite industry was first officially recognized by Governor John K. Tener, when the latter appointed him to the mine-cave commission in 1911. Again in 1920, when the presidential wage commission was named by President Wilson, he was chosen to represent the producers.

In 1893 he began his first term as Mayor of Scranton, serving until 1896. Six years later he was again named to the office of the city's chief magistrate, remaining in office until 1906. In politics he was always a Republican.

Aside from his interest in coal he was a prominent figure in other fields of industry. He was a director in the Scranton Life Insurance Co., the International Textbook Co. and the International Publishing Co. He was at one time a director of the Union National Bank. He was also identified with the Paint Creek Collieries Co.

W. W. Inglis, president of the Glen Alden Coal Co., succeeds Mr. Connell as chairman of the Conciliation Board.

Trade Commission's Usefulness at End, Conduct of Madeira-Hill Case Proves

Methods Savor of Persecution—Strays from Economic to Judicial
Activities—Fails to Profit by Legal Setbacks—Bill
Introduced for Its Abolition

Further evidence that the Federal Trade Commission has outlived its usefulness and has become hopelessly actuated by a spirit of persecution is seen in its conduct of the Madeira-Hill hearing. The tactics resorted to by the counsel for the commission in obtaining certain material for its record is alleged to have approached false pretense.

The Federal Trade Commission in September was told by the President to look into the matter of wholesale and retail prices of anthracite. Thereupon representatives of the Federal Trade Commission waited upon the Harding Coal Commission and asked permission to examine reports on wholesale and retail costs, which had been obtained under the powers vested in the Coal Commission. The request was granted in a letter embodying a formal resolution of the Coal Commission which stated clearly the terms under which the material could be used. Those terms do not authorize the presentation of these papers as evidence in a legal proceeding. Regardless of that, the original returns from some of the companies were incorporated into the record as evidence.

LETTERS UNFAIRLY OBTAINED

Certain letters written by Mr. Madeira to Dr. George Otis Smith were obtained on what is declared to be misleading representations. Dr. Smith was told these letters had been referred to in the Madeira reply to the Federal Trade Commission; Dr. Smith was given the impression that Mr. Madeira had thereby released them. An examination of the formal reply showed no reference to the letters written Chairman Hammond and Dr. Smith.

The letters would not have been made available had the situation been accurately stated. Counsel for the Federal Trade Commission would not allow Dr. Smith to explain the terms and purpose of the Coal Commission's resolution. The original returns were made a part of the record in the face of the clearly stated condition that the original documents must remain in the custody of the Secretary of the Interior, the custodian of the records of the commission. When Dr. Smith was on the stand, the Trade Commission's counsel in substance asked: "You seem to have some personal interest in this case." "I have," replied Dr. Smith; "As a private citizen and as a public servant trying to get at the truth."

There has been some criticism of the Harding Coal Commission because it recommended that federal supervision be vested in the Interstate Commerce Commission. There are some who

would have had the recommendation read "Federal Trade Commission." The conduct of the Federal Trade Commission during this hearing leads many to believe that it is trying for a position in the sun, and makes it clearer that the Coal Commission made no mistake in its recommendation.

This proceeding has brought out with particular clearness the trend of the Federal Trade Commission away from economic activities and toward judicial functions. The trend has been gradual but as time has passed less and less of the Federal Trade Commission's appropriations have been absorbed by its economic work. It has reached a point where many believe it to be usurping the functions of the Department of Justice. It has moved away from Mr. Hurley's constructive conception of making the commission a tower of light to dispel the twilight zone created by the anti-trust statutes.

MISSED LESSON IN MAYNARD CASE

Many are surprised that the commission did not profit by the Maynard case and other legal proceedings which have been brought successfully against it. Instead of indicating that it should be more constructive and less legalistic, these cases seem to have worked the other way. The commission was invited to look into the price of anthracite. This gave an unusual opportunity to be of constructive service. It could have done much toward allaying the feeling of panic which had overtaken buyers at that time. It could have called in the independent operators and probably could have worked out a voluntary arrangement which would have saved consumers large sums. Instead, the commission chose to marshal its whole resources in an effort to run down certain individual cases of alleged profiteering.

WOULD ABOLISH TRADE COMMISSION

This attitude on the part of the commission has resulted in the introduction of a bill by Representative Johnson, of Washington, proposing the abolition of the Federal Trade Commission and the transfer of its activities to the Department of Commerce. Mr. Johnson states that he has presented this legislation because of the failure of the commission to be constructive in its activities.

The decision in the Madeira-Hill case may be handed down Friday. There are many who think the very capable men who comprise the commission, on second thought, may take a stand against a clique within the commission's staff which would make it a muck-raking machine. P. W.

End Hard-Coal Rate Hearing; Early Decision Unlikely

The Interstate Commerce Commission on Dec. 8 practically concluded its hearing on anthracite rates and rates on anthracite substitutes. It is thought probable that the commission will call for briefs and will require oral argument. It is practically certain that a decision in the matter cannot be handed down in time to affect business in this coal year.

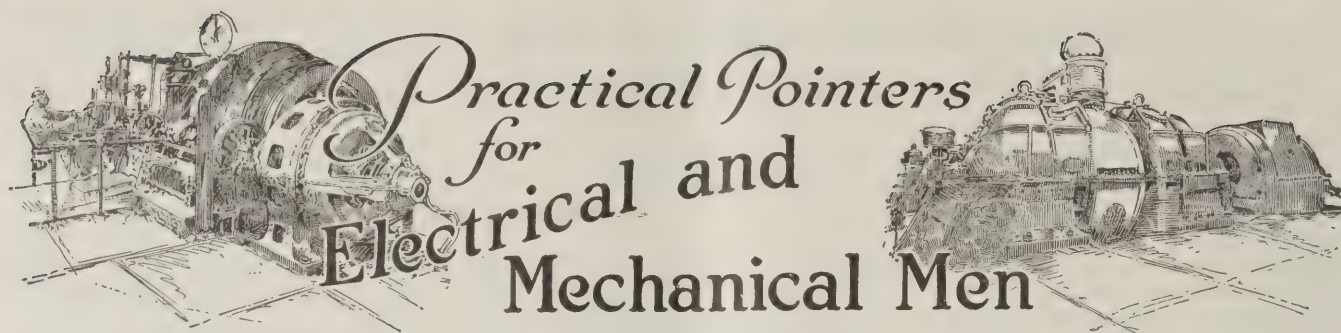

It is admitted that the railroads opposed convincingly the publication of rates from the smokeless fields. Apparently, they established that any all-rail rate to be low enough to move the coal would not be compensatory. If the rates were made high enough to be compensatory, no coal would be moved. Moreover, it was pointed out, 2,000 additional cars would be required to protect a movement of 100 cars per day. Any diversion of the New England movement from southern West Virginia via Hampton Roads would result in the further loss occasioned by idleness of expensive equipment at those ports. The point also was made that any such plan would be contrary to the recommendations of the Harding Coal Commission, which suggested a form of economic zoning to prevent long hauls. Attention also was called to the fact that the commission itself in broadening Ohio differentials had been influenced in part to reduce the haul.

With regard to anthracite proper, little evidence was introduced by consumers. It is possible that the commission will make changes on its own knowledge of the situation, but to attempt to fix rates without having evidence in the record would be an unsound basis for rate making, some contend.

Wholesalers Discuss Proposed Coal Legislation

The executive committee of the American Wholesale Coal Association will open a two-day session in the Whitehall Club, New York City, this morning, at which important matters relating to the wholesale phase of the coal industry and proposed legislation will be discussed. Invitations have been sent to every wholesale coal dealer in New York City and vicinity to attend the luncheon meeting at the club at one o'clock, at which time prominent speakers will discuss the work of the Federal Trade Commission, matters of legislation and that portion of President Coolidge's message relating to coal.

Efforts will be made during the sessions of the Executive Committee to interest the New York wholesale dealers in the work of the association and to point out to them their position with respect to the Federal Trade Commission. Charles L. Dering, of Chicago, president of the association, and Charles A. Owen, member of the Executive Committee from New York City, expect a large attendance.

Direct Determination of Volt Drop of Haulage Circuit

Much has been said and written about the importance of good track bonding on the haulage systems at the mines. Whenever there is a convention of any kind or get-together meeting of electrical men, almost invariably there is some discussion on the subject of bonding. The power losses, maintenance costs, delays and other disadvantages of poor bonding usually are well known to the average electrical engineer, electrician and mine superintendent, but few know just how bad or how good the bonding is in any of the mines.

Eternal vigilance is the motto of many electrical men and by continually following up on the bonding repairs wonderful results have been attained in maintenance of motors and train schedules, to say nothing of the saving in power and the lessened need for large generating and converting equipment to feed the direct-current supply lines.

Where bonding is poor, lines long, loads large and remote from the supply, conditions are the worst. Here it is first of all desirable to feed power into the center of the load or into localized load centers by placing the generating or converting equipment as near to the load as possible. Sometimes it will be found to be highly desirable to locate the supply station inside the mines or on the surface as directly as possible over the load center.

In localities where the coal is thin, and especially where one seam is mined at a time and the load center moves rapidly, a portable converting substation is highly desirable, because of the resulting power saving and flexibility as well as the economic and operating advantages which affect the ledger sheets and the whole personnel from the manager to the miner. We have become so set in the habit of permanently fixing these stations that our better sense of judgment seems to be somewhat tardy in asserting itself.

Another important feature is the shortening of all feeder and return circuits whenever an opportunity presents itself in the development of the electrical feeders and occasionally by a prearranged plan designed to better the whole power-transmission system.

Decision on the type of bond to be used frequently is a matter of track and haulage requirements. The advantages of good bonding are obvious.

Periodic bond testing is necessary on

all important track systems but the real test of the circuit is the drop of voltage under load conditions. Bond testing will localize a fault in the track return, but the resistance of the circuit is dependent also upon the resistance of the feeder system, which often is neglected.

A simple test for determining the circuit resistance is to short-circuit a feeder line to the track and force current into the circuit from the generator. The generator should be operated

TESTING FOR VOLTAGE DROP

With the generator connected as a shunt machine the voltage is built up in the closed circuit between the feeder and return to any desired load. The voltage necessary to force any given amount of current through the circuit is equal to the drop in that circuit when operated at that given load during normal operation.

as a shunt generator for the test and the voltage should be gradually built up from zero by control of the field rheostat. By taking instantaneous current and voltage readings at different loads an indication of the voltage drop in that part of the system is directly obtained. Such tests may be carried on in various parts of the mine and poorly bonded sections localized. Evidence thus obtained gives tangible proof of poor voltage conditions and can be used to advantage at conferences with superintendents, foremen and electricians.

Power-Plant Problem of the Coal-Mining Company

With reference to Mr. Butcher's letter which appeared in the Nov. 22 issue of *Coal Age* I wish to offer the following remarks:

The experience outlined in the letter referred to above is much the same as happens to most engineers entering the coal fields for the first time. The practices and types of installation seem almost criminal until a thorough study has been made of the various situations,

after which there seems to be more or less justification for some of the situations that seem so bad at first glance. It must be remembered that a great many of the power installations in coal mines in the past have had little or no engineering, but just "grew," like "Topsy." The mine superintendents were largely selected for their knowledge of coal mining, with little thought to the power end of the situation. The result was that a great deal of the power equipment was purchased on the recommendation of the manufacturers, so that in many cases the equipment was not best suited to the needs of the mine.

REASON FOR SIMPLE ENGINES

There is a fairly good reason why most isolated plants are equipped with simple automatic engines, running non-condensing. This is due to the fact that the type of experienced labor available around many of the mining communities is of a poor grade, and only the simplest kind of apparatus will give satisfactory service. It would be folly to install high-grade condensing equipment when the type of labor necessary to operate this equipment is not available.

In order to utilize the exhaust steam it is necessary to install low-pressure turbines and a complete condensing equipment. Even where water is available, this requires a much higher grade of labor than is necessary for a simple non-condensing engine. In addition, this requires a considerable layout and in many cases there is no place to utilize the additional power generated.

WATER SUPPLY IS IMPORTANT

In answer to the question, "Can a public utility sell power for less than it can be made for using waste steam at the mine?", it has been amply proved that in the large majority of cases power can be purchased at an equal or lower rate than it can be made by a mining company. This is proved by the fact that a large number of mines have changed over to central-station power during the last ten years, and with scarcely a single exception, the power is costing the mining company less than it did before, and in a large majority of the cases the mining company would not for a minute consider going back to the making of its own power. One of the principal reasons for this is that the most important essential for satisfactory power production is a plentiful supply of good water.

It is rather rare that a good supply of water is available in the mining sections. The poor water usually available requires water-treating plants, which, in turn, require a fairly high-grade type of labor to keep the water-treating plant in successful operation.

A coal-mining company is in business essentially to produce and market coal, and the generation of power is more or less foreign and requires considerable technical ability, which does not exist in the average coal-mining organization. For this reason power is not generated under the best conditions and at as low a price as it should be. Coal-mining companies, like industrial organizations, have a limited amount of capital, and they can employ this capital at much better advantage in the development and operation of the coal mine than they can in the installation of a power plant. When a power plant becomes overloaded it frequently is necessary to install new boilers as well as new engines and generators. This requires a considerable outlay of capital, which the average coal mine cannot easily obtain. With central-station power the increase in capacity can be obtained at low expense and in very much less time than would be the case with an isolated power plant.

BETTER BOILER-ROOM PRACTICE

The older boilers around coal mines usually were of the fire-tube type, while the most recent installations are putting in the water-tube type of boiler. The installation of stokers depends somewhat on the type of fuel and the saving in labor that would be obtained by their use.

It must be remembered that a large number of the coal mines were purchased by the present operators, who are not responsible for the type of power equipment that existed when they purchased the property. A large number of operators realize that their equipment is not what it should be, but they would have considerable trouble in persuading a board of directors to expend considerable sums in bringing the plant up to date. During the next two or three years the competition in the coal business is going to be very keen, and a number of the inefficient coal-mining plants will be compelled to shut down. The coal companies that expect to stay in business will have to be sure that their power plants and their entire mining equipment is operated in a most efficient manner, and where engineering ability does not exist in the coal-mining companies it should be employed from outside sources, if the coal companies expect to keep in business at a profit.

EACH MINE A DIFFERENT PROBLEM

It should be remembered that no two coal-mining problems are alike; in fact, there is a vast difference in the conditions that exist in different mining sections. No general recommendation can be made in regard to the type of power plant and whether central-station power should be used or not, since each mining problem should be analyzed

thoroughly before any recommendations can be made. In general it is safe to say that purchased power should be utilized whenever available, and where not available, if the mine is small, a simple automatic non-condensing engine or non-condensing turbine should be used in generating power. For the larger mine it will often pay to put in condensing equipment where high efficiency can be made to pay. The conditions in the average isolated power plant in coal mines are very much as pictured, and the only way to remedy these defects is to employ intelligent engineering toward revamping the plants and introducing more efficient methods of generating and utilizing power.

GRAHAM BRIGHT.

Pittsburgh, Pa.

Resistance of Electrical Circuits

The ohm, the unit of resistance, usually is calculated for a given circuit or part of a circuit. There is a definite relationship between the voltage, current and resistance of a circuit. This relationship has been stated in a law known as Ohm's Law. To get an understanding of how the volts, amperes and ohms are related, we must again refer to our water analogy. First of all, if we have a pipe line and we wish to force water through it, we must have pressure. This pressure is similar to voltage; the flow of water is similar to the current in the electrical circuit.

The resistance of the pipe to the flow of water is similar to the resistance of a conductor to the flow of electrical current. In electricity this resistance is measured in ohms. Obviously, if we have a certain pressure and desire a certain flow of water to pass through a pipe, if the pipe is small it offers a high resistance; in fact we may not

TAKING MEASUREMENTS FOR DETERMINING RESISTANCE

The value of the resistance is determined by taking voltage and current readings on the meters and solving by use of formula No. 3.

be able to force our given amount of current through the pipe without increasing the pressure. By increasing the pressure to the required value, however, we can force the desired quantity of water through the pipe. If the pipe is large in diameter—that is offers little resistance to the flow of the water—the pressure necessary to force a given quantity of water through the pipe becomes small.

In electrical circuits the condition is quite similar. To force a given current through a conductor, the greater the resistance of the conductor, the greater will be the voltage to force the current

through. Therefore a circuit having a low resistance will carry a heavy current and will require a low electrical pressure, while a high-resistance circuit will require a high pressure even to force a small current through the circuit. Ohm's Law establishes the relationship between the volt, ampere and ohm, and may be stated thus: The current flowing in a given circuit is equal to the voltage divided by the resistance. This same formula may be expressed in two other different ways; namely, the voltage equals the resistance times the current and the resistance equals the voltage divided by the current.

Using the following letters, this formula may be represented as shown:

I represents current in amperes;

E represents pressure in volts;

R represents resistance in ohms.

Then

$$(1) I = \frac{E}{R};$$

$$(2) E = R \times I;$$

$$(3) R = \frac{E}{I}.$$

Saving the Centrifugal Pump Motor

A few weeks ago our company had a rather interesting experience with the operation of a centrifugal pump. Unfortunately, however, the experience came when we did not have much time to spare.

The pump referred to is a large 1,000 - gallon - per - minute 400-ft. head centrifugal pump. For years this pump and its driving motor had been working without any great amount of repair and maintenance cost; in fact it was almost automatic in that constant attendance rarely was required.

This pump has always been operated against a static head of about 360 ft.; the friction in the pipe line probably is nearly equal to 40 ft., and therefore the pump and motor has been working at full capacity.

One day when everything seemed to be going fine a fire developed in one of the levels above this pump and it became necessary to tap the column line of the pump to supply water to the fire region.

The motor on the pump was running at normal load until the valves supplying the fire lines were opened. Soon after the water in the fire lines began to flow, the motor became overloaded and the pump man did not know what to do. The pump could not be shut down, so he left it operating but called one of our engineers.

When the engineer arrived the motor was becoming quite hot, but instead of shutting it down the valves on the fire lines were partly closed. The result was that these valves introduced sufficient friction in the lines to make the discharge pressure on the pump about equal to normal when operating on its usual column line and the motor load came back to a point within its capacity.

ELECTRICIAN.

Problems In Underground Management

Means for Extension and Removal Of Rails at Ends of Rooms

Plan Designed to Speed Rail Recovery So That Track May Be Withdrawn Before Roof Falls—Requires No New Equipment Unless Steel Ties Are Not Being Used

BY THOMAS J. DOWNING, JR.

General Manager, Logan County Coal Corporation,
Lundale, W. Va.

Mine ties of steel as compared with wood ties give greater headroom between the top of the rail and the roof, lessen the height the miner has to raise his coal in loading it into the car, last longer, are handled and stored with greater convenience, are more uniform in quality and size, are laid more easily, cannot be used so as to give the wrong gage but almost above all permit of prompt recovery of track from the zone of danger when a fall is imminent near the face of a room or in the pocket of a pillar that is being drawn back.

As they are not cumbersome in either size or shape and as the method by which the rails are attached to them is one that makes tracklaying easy, miners can readily draw them back when a fall of roof impends.

The means for extending and removing extension rails in the mines of the Logan County Coal Corporation, at Lundale, W. Va., is illustrated herewith. It has been used for many years in those workings with such success that we have felt warranted setting it up as one of our standard practices. It not only provides a way of extending two slide rails from the permanent room track to the face but it also en-

ables the miner to pull them out of danger with little manual effort whenever conditions at the face indicate the possibility of a roof fall.

As the illustration shows, the rails used for extension are of full length, and slide along the outside of the permanent rails. Two switch points are used in jumping from the permanent to the slide rails. The first attachment of a steel tie to the slide rail is made at the switch point by causing the button on the tie to engage the switch point.

Then two ties are placed on each side of the joint between the permanent rail and the butt end of the switch point. Those portions of the slide rails which extend in front of the switch points are joined by ties spaced at regular intervals as if the track were permanent. It will be noted that the ties to the rear of the switch point do not connect the permanent track in any way with the slide rails.

When this method is used for the laying of room track, no gob must be left near the loose rails. Otherwise they might be raised thereby to such a level that they would catch the cars passing over the track adjacent to

them, thus causing them to be derailed.

The advantage of this simple arrangement is twofold, as the track may be both laid and torn up with facility. The kicking open of a few lug nuts or clips allows the slide section of the track to be dragged bodily from under a manifestly weak piece of roof. Much steel may be saved by adopting this or a similar arrangement in pillar sections, wherever prevailing dangers and the labor involved otherwise do not warrant attempts at recovering steel once it is buried. Details for governing the exercise of this practice are scarcely necessary. Whether the track is laid to the face by company men or the miners themselves, the bosses whose duty it is to see that the workmen do their work in a manner that will avoid accidents at the same time can save steel by giving proper instructions when necessary.

Fighting Coal-Dust Menace In the Transvaal

Says H. Walker, inspector of the Scotland division of Great Britain, in his report for 1919: "The usual attitude at any particular mine where coal dust occurs is a ready acceptance of the fact that, generally speaking, such dust is dangerous, but a firm belief that in the mine under consideration it is perfectly harmless. Such an attitude is difficult to combat. All argument, other than a rude awakening in the shape of a disastrous explosion, I fear, would be futile." He could not have put the matter more fortunately had he been writing about the United States and its coal mines.

With these words of Mr. Walker, J. P. Hindmarsh prefaces his remarks on coal-dust explosion prevention in the "Annual Report of the Department of Mines of South Africa, 1922," as acting chief inspector of coal mines. He says "The necessity for dealing with coal dust becomes more and more pressing as the mines get older and larger areas are opened up. Coal begins to flake off the pillars left standing, and this in turn is ground into dust by the feet of the men and horses and the wheels of cars in transit."

He adds that at least "one mine in this state has commenced rock dusting." The Abermain Seaham Collieries, Ltd., has installed at its No. 2 Seaham Colliery a ball mill for crushing rock. It is belt-driven from a vertical steam engine of 25 hp., a conveyor being built from the shaft top to the mill, which is

SWITCH-POINT METHOD OF EXTENDING TRACK AT WORKING FACE

Ordinary steel ties are used but switch points are provided, held in place at both ends by ties. These switch points, of course, are kept closed at all times, as they furnish the means of passing from the permanent to the extension track and back again.

about 20 ft. therefrom. The shale is obtained from the roof of the Borehole Seam.

In order to prevent any coal from being mixed with it, it is hand-filled into cars, the rock being taken from the goaf edge of pillars and sent out of the mines. When the cars reach the top of the shaft they are tipped direct into a chute, or hopper, at the mill. The shale runs down the chute onto the mill floor and is there broken into cubes not larger than 6 in. across and fed into the mill by hand. The man attending the engine and mill breaks the stone and feeds it to the mill, the capacity of which is 1,000 lb. per hour of the finished product.

On leaving the mill the rock dust falls into a small hopper and then into a car standing on rails at the surface level. When the car is full it can be run direct into the cage at the surface. When it reaches the mine workings it is distributed along the haulage road (either loose or in bags) into stations about 220 ft. apart. In practice this distance has been found not too long for the thorough rock dusting of the roadway. The dust is distributed by ejectors operated by compressed air at a pressure of 80 lb. per square inch. A short length of 1-in. hose is attached to the air main at one end and to the ejector at the other, the nozzle being reduced from 1 in. to $\frac{3}{8}$ in. Rock dust is filled into the funnel-shaped vessel by hand and is blown out of the sprayer in a dense cloud which is carried forward and distributed by the air current.

AIR WILL CARRY DUST A MILE

Dust has been deposited in this way over a mile from the injector with an air current having a velocity of about 480 ft. per minute, but to make an effective distribution it has been found necessary to have injectors every 220 ft., as previously stated. In this way a ton of dust can be sprinkled over the gallery in about an hour. The rule at present is to distribute 2 tons each shift, the dust being thus scattered only at night.

The cost of preparing and distributing the dust is estimated at about 2c. per ton on an output of 1,200 tons per day, the charge covering interest and depreciation. This does not include cleaning up or preparing the roadways. In preparing the roadway before stone dusting all the debris is not sent out of the mine. A new face wall is built, and the debris put behind it. The cost of erecting and equipping the mill complete was about \$8,500. The stone dust, being of a light color as compared with the dull black surface of the coal, noticeably improves the illumination of the roadways.

The shale contains water evaporated at or below 100 deg. C., 1.25 per cent; volatile matter and water evaporated above 100 deg. C., 10.47; combined silica, 22.68; free silica, 33.30; alumina, 15.64; ferric-oxide iron, 8.60; titanium dioxide, 0.60, and carbon, 1.70. The free silica may appear high, but it may be said that the Altofts shale has 35

SPRAYS INERT DUST OVER LOOSE COAL IN ROADWAY

Set 220 ft. apart these ejectors cover the floor, sides and timbers of roadways with fine dust, which makes them almost explosion-proof.

per cent of that ingredient out of a total silica content of 52 per cent. Long experience has shown that it could be used with perfect impunity in the dusting of mines, not being harmful to the lungs. The silica dust is believed not to be injurious when mixed with coal dust. Under the microscope no sharp angles can be seen and the dust is very fine.

It will be noted in passing that the rock is broken down by hand and not by a jaw crusher, as might be more economical. Nothing is said as to the cost of the air. The plan of storing the dust from the roadways in the mine is not one which would seem likely to meet with commendation, even though a face wall is left as a partial defense against the raising of a dust cloud.

Peril in Use of Carbide Lamp When Testing for Gas

BY W. H. LUXTON
Linton, Ind.

Narrow, indeed, are the escapes of those who carry a carbide lamp to supplement the light from their safety lamps when making an inspection for gas. A few years ago, one fireboss replaced another at a coal mine because the latter was desirous of taking a much needed vacation. While making his examination with a safety lamp the fireboss who was preparing to leave carried a carbide lamp with him, being careful to hold it low. All went well—that morning. When the new fireboss made his visit he also took a carbide lamp, but left it well back when approaching the face of a working place.

He soon had occasion to realize that his precaution was well taken. On entering one of the places which he had to examine he ran into a large body of gas at a point 80 to 100 ft. from the face of the entry. What the result would have been had he carried his

carbide lamp with him may well be imagined.

The ventilation of that section of the mine depended on the operation of a booster fan, which was running when he reached it. He would have known full well, had he found it standing still, that the headings would be full of gas. He did not know, however, that the fan had been stopped and was started again only a short time before his arrival by one of the night shift who failed to notify the fireboss of the circumstance. Just such happenings as this have cost many a fireboss his life, and only his leaving the carbide lamp which he carried on his trip a safe distance behind saved that particular fireboss from a similar fate.

Use Electric Sprinkling Tanks To Water Roads in West

Without sufficient pressure to wet down roof and ribs no water car can be effective in mine sprinkling. The sprinkling of roadways with a mere tank car is not effective, as it does not touch the dry, fine, settled dust on timbers and rib ledges. This was the dictum of D. Harrington in a report on the prevention of coal-mine explosions to the chairman of the committee on safety of the Rocky Mountain Coal Mining Institute.

In discussion William Littlejohn, general superintendent of the Utah Fuel Co., Castle Gate, Utah, said that the coal at the Castle Gate mine was the most inflammable that had been tested at the Pittsburgh Station of the U. S. Bureau of Mines. He said that at Castle Gate and Sunnyside had been built two 500-gallon tank trucks each with a pump on one end of the truck driven by a motor which gets its power from the mine circuit. The other end of the truck has a semicircular perforated pipe. The truck is hooked onto an electric locomotive. When the pump is started it throws a fine spray which wets roof, sides and floor. With it a roadway that a man with an ordinary hose and spray could sprinkle only in two shifts, could be wetted down in half a day and the job would be more thoroughly done.

The company is expecting to use the system on rope haulageways, which, of course, will have to be run by a reel from the feed lines. The conductor lines on these reels will have to be about 400 ft. long. George B. Pryde, the general superintendent, said that the Union Pacific Coal Co. had also built two tank cars of 600 gallons capacity which are connected with hose so that the water can flow from one tank to the other. A centrifugal pump mounted on a truck is connected to the front tank. This pump takes its power from the trolley wire. The discharge from the pump being perforated it sprays the floor and sides of the entries. This water train will be used on such main haulageways as have no sprinkling equipment.

Production and the Market

Weekly Review

Weather conditions and the usual holiday spirit dominate the soft-coal market. Production is in keeping with the general downward tendency toward the end of each year; in both hard- and soft-coal fields there is a letting down in demand. The Geological Survey summarized conditions last week by noting that twenty-one districts out of thirty-two record a gain in time lost because of lack of demand; and twenty-four districts are operating with losses of 40 per cent or more of full time capacity due to poor market.

Thanksgiving Day, which was more generally observed than in previous years, resulted in a heavy cut in production, output during the week ended Dec. 1 amounting to 8,923,000 net tons, a decline of 1,237,000 tons from the previous week and 14 per cent less than for the corresponding week of last year. Output for last week, it is estimated, will not exceed 10,000,000 tons. For the first 283 working days of the present year production has been 506,813,000 net tons, according to the Geological Survey, which is about 33,000,000 tons below the record year of 1918, but larger than the low years of 1919, 1921 and 1922.

PRICES REFLECT LOW DEMAND

The downward tendency of the market is reflected in *Coal Age* Index as of Dec. 10, which stands at 180 as compared with 181 for the previous week, with an average price of \$2.18, a drop of 1c. and a new low mark for the present year. Increases in Standard, eastern and western Kentucky, Hocking and Kanawha districts were overcome by decreases in southern Illinois, Mt. Olive, Springfield, Clinton, Pocahontas, Cambria and Somerset coals.

There was a drop in demand in all domestic sizes of southern Illinois coal and with the exception of screenings the market in the central and western parts of the country was lifeless. In most parts of Ohio the smokeless market was draggy and dull, the greatest activity

being noted in slack. Retail dealers are stocked up and householders do not want to add to their winter supply. Steam coals move slowly and with lake shipments almost ended it is expected that demand for everything except slack will show a more pronounced falling off. Pittsburgh is in poor shape as far as demand goes, while operators in central Pennsylvania assert that they see a slight betterment. There is no improvement noted along the Atlantic seaboard.

In the East there is moderate interest in the market after Jan. 1. Consumers are inquiring for contract

	Week Ended Dec. 3	Season to Dec. 3

Totals	601,238	31,230,520

prices covering the first quarter of 1924, but some operators are inclined to hold back for the open market. It is reported that bunker prices covering the entire twelve months had been quoted at \$6.25@ \$6.50.

Easier conditions are evident in the anthracite market. There is less urgency and with less hard coal going westward for lake shipment quotations for independent product are slightly lower than they were a week ago. Production for the week ended Dec. 1 is estimated to have

been 1,748,000 net tons, a drop of 352,000 tons from the previous week, due to the holiday and the last day of the week being pay day for the workers. It is not anticipated by the Geological Survey that the output for last week reached 2,000,000 net tons.

France again led all other countries as buyer of coal from Baltimore during November, recovering the lead attained during August and September. During November thirteen vessels leaving Baltimore carried 62,389 tons of bunker and cargo coals, and one ship took 4,050 tons of coke. In October of this year ten ships took 51,753 tons of cargo and bunker coals, and two ships carried 5,375 tons of coke.

Midwest Slumps Lower

A drop in prices on all domestic sizes of southern Illinois coal took effect Monday of this week. Warmth prevails throughout the whole central and western part of the country and the market is absolutely lifeless on everything but

screenings. There would be little interest even in steam coals were it not for the low output of practically every mine. The price of fines has risen enough to move several producers to begin crushing their lump.

Southern Illinois screenings brought \$1.75 at the end of last week and were strong at the price. Central Illinois fine sizes ranged around \$1.50 and Fourth and Fifth Vein Indiana screenings, respectively, were moving at those two quotations. The only hope of Midwest operators for the rest of the month lies in steam coal, barring a blizzard of considerable length, for there is little money in the new scale of prices. Franklin County lump, egg and nut in the new circular are now \$3.75, \$3.50 and \$3.25 as compared with previous figures 25c. to 60c. above those levels.

Practically all domestic coals are weak at whatever the circulars call for. East Kentucky, which has been striving to hold firm at \$3.50, is sinking and west Kentucky lump is going at almost any bid. The flood of cheap Pocahontas mine-run—\$1.50@2 at the mine—is having a marked effect upon trade throughout Indiana, Illinois and parts of Iowa and Michigan.

Several Illinois mines have been idle for over a week,

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

	1923		1922	
	Dec. 10	Dec. 3	Nov. 26	Dec. 11
Index	180	181	186	325
Weighted average price	\$2.18	\$2.19	\$2.25	\$3.93

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

unable to move sizes. This is causing a shortage of screenings. Some mines work one day a week and a few get as much as four days. Railroad tonnage is light. Car supply is good and general dissatisfaction prevails throughout all southern Illinois fields among the miners. In the DuQuoin and Jackson County field operations have almost ceased, excepting at a few mines that get three and four days a week. Prices range up to but seldom above cost.

In the Mt. Olive field everything is at a standstill on account of inability to move domestic sizes. The smaller steam sizes are all cleaned up. The same condition prevails in the Standard district, where screenings and small nut are scarce and everything else is unbilled. The Mt. Olive district gets about one day a week work. In the Standard district they get from one to two days a week, excepting railroad mines.

St. Louis Does Little

A little cool weather keeps some coal yards moving small quantities of the middle grade coal. Domestic demand is very light and there is little moving, with all yards loaded. The consuming public will not buy Franklin County lump at \$8 when Mt. Olive is \$6.50 and Standard \$5.25. There is no demand for smokeless, anthracite or coke. Country domestic is also light. Local wagonload steam shows some

improvement. Carload is slow and the steam demand here is usually for shipment to Chicago or the north.

Kentucky Unhappy Too

General reports from the west Kentucky field indicate that business is slow and that additional mines are closing down through lack of market. About sixty of the really permanent type of mines are down, and the balance are running irregularly at about 30 per cent of potential time and 28 per cent of potential capacity. Strip mines are reported to have shipped something over 1,700 cars of coal in November—a little over 10 per cent of the total moved from the field.

Operators are endeavoring to push up screenings in price, but are meeting with cheap screenings from eastern Kentucky and other sections. Some mines are producing little prepared coal, and haven't many cars of screenings to sell, or have contracted or sold for the time being, with the result that they are quoting high to force a stiffer market, but without much result.

Car supply is full on all Kentucky roads. Prices show little change, though some eastern Kentucky coal in distress lately has sold down to the bottom. Horse Creek, Harlan and Hazard have all contributed their share of this.

Northwest Trade is Somnolent

Nothing has happened during the week to awaken any fuel interest in the Northwest except the virtual wind-up of the shipping season. Tremendous dock supplies are now at the Head-of-the-Lakes and all the other ports down to Milwaukee, both of soft coal and anthracite. This is so comforting to Northwest consumers that the warmth of the week lulled them practically to sleep and trade is flat. Shipments off the docks is slow.

Government engineer office figures show total receipts at the Head-of-the-Lakes up to Dec. 1 to have been 12,529,758 tons—over 11,000,000 tons of soft coal and 1,400,000 of anthracite—which compares with only 7,125,000 tons last year and an average of about 9,120,000 tons for the past ten years. November shipments to Duluth, 1,440,000 tons of soft coal and 215,321 tons of hard, were greater than was expected. Insurance goes off Dec. 12. Milwaukee season totals to Dec. 1 were 3,155,000 tons of bituminous and 930,000 tons of anthracite.

West Idles Along

Prevailing pleasant weather holds down the coal business throughout the Kansas City, Denver and even the Salt Lake City regions in spite of a snow flurry in Utah. Working time in that state is barely 50 per cent and low production aids the screenings price a little, but only enough to stop the dumping that has been general. Utah mine prices on lump, egg and pea are \$4.50, \$3.75 and \$2. The Colorado market continues to slump with the December summer weather. Working time in a majority of the mines in the state averaged twenty-five hours last week. Price circulars have not changed since Sept. 1.

A slight surplus of Kansas lump and nut has begun to collect at mines, with no relief from the screenings surplus, evident all the season. There is little demand for Arkansas semi-anthracite of any grade and there is talk of closing down more mines throughout the Southwest. Various operating concerns report their mines working from 40 to 60 per cent of normal. Circulars remain the same as last month, though reports of shading are becoming more numerous.

Ohio Market Dull

The market for smokeless coals in the Cincinnati territory continues draggy and dull. Weather conditions are not suitable for coal consumption. Slack no longer goes begging, although the demand for other coals is slow and inactive. Supplies at Toledo are reported to be heavy. With the gradual dropping in the price of domestic coals and the disposition of mine run to hold up, more and more of the heavy producing mines still running have turned to the making of unscreened coals.

The dullness in the Columbus market was attributed

largely to weather conditions. Dulness prevailed in both the steam and domestic trade and it is the belief of producers and shippers that lower temperatures will be needed to stimulate the market. Retail dealers are well stocked and householders refuse to buy. With the end of the year near dealers are inclined to await the inventory season before adding to their supplies. There is no activity in the steam trade. Reports received by the Southern Coal Exchange show that during the week ended Nov. 24 output from 443 mines, with a capacity of 695,490 tons, amounted to 168,295 tons. "No market" was responsible for a loss of 491,544 tons.

Conditions in the Cleveland market are slow. Steam coal does not move in good volume and domestic coal consumption is not large because of weather conditions. Production in the eastern Ohio field is lower and a still greater decline is expected to follow the stoppage of lake shipments.

Operators and dealers in the Pittsburgh district alike regard the coal market as in very poor condition. Prices on slack are higher and on steam mine-run a shade firmer. The advance in slack was expected, with the cutting off of a large production on account of the ending of the lake season, and to make the situation worse steam lump softened. Sellers of bituminous coal have been unable to develop any interest among buyers in a possible strike or suspension on April 1, buyers acting as if it was a foregone conclusion that the scale will be renewed on the old basis without any interruption. Conditions at Buffalo continue dull with practically no demand. More West Virginia coals are being received than is generally the case.

New England Industries Marking Time

Industries in New England for the most part are marking time and there is nothing in the present situation to justify adding to present large stocks of coal for steam use. There is no buying of any moment and any improvement in demand is now unlikely until after the holidays. A few special lines of textiles are having fair business, but the bulk of New England's cotton-goods trade is stagnant. If prices move up in January it is possible that there might on that account be somewhat better inquiry for bituminous.

The Hampton Roads agencies are very much in the doldrums. Several of the large producers have restricted output to the barest requirements of contract obligations and tonnages are correspondingly light. Prices continue on last week's level, an occasional sale in cargo lots returning to the operator \$4.35@\$4.50 per gross ton, f.o.b. vessel, or \$1.83@\$1.98 at the mine, for coal No. 1 Navy standard grade.

On cars Boston and Providence there are quotations of wide range, \$5.50@\$6 being "mentioned," but it is said that 500-ton lots are still being disposed of at \$5.25@\$5.40.

All-rail inquiry is almost nil. Reasonably good grades of Pennsylvania coals roughly classified as "Pool 9" are offered down to \$2 at the mine, with less favorably known coals quoted at \$1.60@\$1.75. There appears no opening for coal all-rail so long as the New River and Pocahontas factors are obliged to hammer down prices in order to move coal.

There is coal from the Pennsylvania districts moving by the water route, especially from Philadelphia, but investigation shows the cargoes are made up either of gas coal for

illuminating purposes or they are going forward on purchases made at a time when Southern coals were much higher in price.

Better Tone on Seaboard

The soft-coal market at New York boasts of a better tone. Inquiry is greater, but actual business is slow. The tidewater market is stronger and prices firmer. Consumers are inquiring as to the prospects after Jan. 1 and until April 1, when the present wage agreement with the soft-coal producers expires. Some operators are inclined to take chances in the open market after Jan. 1, instead of making contracts covering the first three months of 1924. Receipts at tidewater piers last week were well above the previous week, while daily dumpings for the first five days of the week at four of the largest piers averaged 380 cars. No change in conditions was noted at Philadelphia. Demand remains quiet. With the exception of slight increases in the various grades of soft coal at Baltimore that market shows no change. Demand is poor and dealers have a hard time booking new orders.

Conditions at Birmingham present no encouraging features. Buying of commercial coal is practically at a standstill, but there has been a slight improvement in domestic sales and more favorable conditions exist for further betterment in the demand of household coals. Railroads are stocking some coals for the holidays, but on account of the limited schedule on which mines are now operating the holidays will have little effect on the output.

Anthracite Demand Easier

The anthracite market is easier. Cancellations continue to be received by some New York wholesale dealers, and retailers find that receipts of the favorite sizes are larger. Egg and pea coals are easy, while stove and chestnut are being received in large enough tonnages to take care of immediate needs. Some retail dealers in sections of New York City are advertising all sizes for immediate delivery. Quotations for independent domestic coals are gradually lowering. Pea coal was offered during the week alongside, New York harbor, on a basis of about \$6, f.o.b. mine, and it was said that a public utility corporation had received bids for more than 1,000 tons of this sized coal at a similar figure. The steam coals are hard to move and quotations for the cheaper grades are low.

Conditions at Philadelphia remain quiet but dealers find no difficulty in placing all the stove and chestnut sizes they receive. At Baltimore although dealers complain of the lack of shipments, there is no great rush on the part of consumers.

The general tone of the Connellsville coke market is not as good as a couple of weeks ago and is not justifying all the expectations recently entertained by operators, based on the recent pig-iron buying movement. The report is confirmed that two furnace interests contracted for first-quarter coke at \$4.40, but that particularly good coke was involved. Standard coke is being offered at around \$4.25. Two makers of particularly high-class foundry coke have put out prices for first quarter at from \$6 to \$6.50 and it is said some contracts have been closed. Production of beehive coke during the week ended Dec. 1, according to the Geological Survey, amounted to 244,000 net tons, as compared with 257,000 tons the previous week.

Foreign Market And Export News

British Coal Production Increasing; Prices Show More Strength

Quotations on various grades of British coal for the week ended Dec. 8 show a substantial increase over the previous week, as a result of a firmer demand. Production is increasing, output for the week ended Nov. 24 amounting to 5,726,000 tons, according to a cable received by *Coal Age*, as compared with 5,574,000 tons the previous week, a gain of 152,000 tons. Output for the corresponding week of last year was 5,471,800 tons.

The Welsh market is much steadier and all the principal operators report having sold their output to the middle of December. Inquiry is steady, but rough weather is delaying shipping. Operators are well pleased over the outlook for December and the early part of January.

French demand is more active but from the rest of Europe inquiry is spasmodic, with Germany buying meagrely. A normal demand is coming from Italy, with a stimulated inquiry from backward shipment. It has been announced that the credits for the purchase of British coal on German account have been partially arranged.

The Newcastle market is strong, the steam coals being materially stiffened by a contract from the German State Railways for 400,000 tons; as a result of the financial credit which has been arranged in London. Shipments are heavy; all sections of Durham coals are active and coking grades are in full demand.

Hampton Roads Receipts Decline

Receipts of coal at Hampton Roads were slower last week owing to the continued strike on the Virginian Ry., resulting in a somewhat upset market. Prices stiffened in consequence.

Coastwise business picked up somewhat, bunkers held their own and foreign trade continued on the downgrade. The prospect for better coastwise trade was brighter, although bunker business was not expected to show material improvement. It is expected that when grain movement becomes active bunker

business will show much improvement.

Domestic prices slumped twice, from \$12.50 to \$10, while anthracite prices were forced down to \$16, unusually favorable weather and slackened demand causing prices to decline.

French Coal Market Dull

Conditions in the French industrial coal market are dull due to less activity in plants and heavy unfilled orders. There has been a slightly better movement of house coals however. Announcement has been made that prices for the various grades are to be raised in the northern coal fields, the increases ranging from 5 fr. to 10 fr. and are to be applied according to mine up to Jan. 15.

The coke situation is improving. During the first twenty-one days of November receipts amounted to 139,000 tons. It is expected that the price for French coke will be increased 10 fr. and a similar increase will be made for German product. It is also expected that Belgian grades will be increased 2.50 fr.

France and Luxemburg during the first ten days of November received 71,900 tons of reparation coal; 98,900 tons of coke and 10,800 tons of lignite, a total of 181,600 tons, as compared with a total of 148,500 tons during the last ten days of October.

Imports of coal during October amounted to 1,935,821 metric tons as compared with 2,619,831 tons, in September, while exports were 121,915 tons in October, as compared with 156,137 tons in the previous month. Coke imported was 282,806 metric tons, as compared with 280,516 tons in September and 44,082 tons was exported in October, as compared with 50,944 tons in September.

Hungary's Coal Production

The mines of Hungary produced 1,724,895 metric tons of coal during the second three months of 1923, as compared with 2,082,626 tons the first quarter of the year, making the total production for the six months 3,807,521 tons, says Vice Consul Reineck, of Buda-

pest, in a report to the Department of Commerce at Washington. The decline in production during the second quarter was caused by a reduction in working hours, many strikes the result of wage disputes, and miners returning to their homes in Czechoslovakia when the operators abandoned the practice of paying part of their wages in Czechoslovak currency. Some progress has been made in the mining industry; two new mines have been opened, and the larger operators have completed surveys for the purpose of extending their workings. Two of the larger operators the report says, have purchased and installed new equipment and begun work on a larger scale. During the first half of 1923 Hungary imported 38,242 metric tons of lignite, 424,550 tons of bituminous coal; 69,319 tons of coke and 1,549 tons of briquets, while its exports were 6,344 metric tons of lignite; 120,799 tons of bituminous coal and 2,741 tons of coke.

Traffic News

To Probe Lignite Rate "Plot"

President Coolidge has directed the Interstate Commerce Commission to make an investigation into what appears to Governor R. A. Nestos to be a conspiracy to destroy the coal mining industry of North Dakota by increasing the freight rates on lignite. This action was taken following the receipt of a telegram by the President from Governor Nestos asking for a Congressional inquiry into the proposed advance, which he says, if granted, would virtually destroy the industry.

Governor Nestos has been joined in his request for an investigation by U. S. Senator Shipstead, of Minnesota, who wrote the Interstate Commerce Commission stating that the proposed rates are confiscatory and will throw thousands of laborers out of employment. He adds that the rates are of such a character that they will prevent the movement of lignite and thereby favor Eastern coals.

Governor Nestos' appeal to President Coolidge supplemented instructions to the State Attorney General to investigate to determine if sufficient evidence of conspiracy to violate the Sherman Anti-Trust law has been obtained to be laid before the federal Grand Jury. The railroads have declined to abandon their petition for rate increases and, in response to the protest, the traffic manager of one Northwestern railroad declared that the proposed advance was made on demand of "our connecting lines." Rates temporarily suspended by the Interstate Commerce Commission, pending a hearing.

Soo Coal Traffic Still Heavy

During November 1,918,249 net tons of bituminous coal passed through the Canals Sault Ste. Marie, as compared with 2,031,084 tons in the preceding month. Of this amount 1,902,506 tons went through the United States Canal and 15,743 tons through the Canadian Canal. Anthracite handled amounted to 238,800 net tons, compared with 200,600 tons the previous month. The tonnage passing through the United States Canal was 230,250 tons, the balance going through the Canadian waterway.

Seek Rate on Topographic Basis

George T. Bell, attorney for the Southern Wyoming Coal Operators' Association, on behalf of the Rock Springs-Kemmerer district, has submitted a brief to the Interstate Commerce Commission in connection with the complaint of the Colorado and New Mexico Coal Operators' Association against the Denver & Rio Grande Ry. in which he contends that the Rock Springs-Kemmerer operators "are entitled to an adjustment of rates predicated on a parity between Rock Springs-Kemmerer and Walsenburg be-

cause the topographical, operating and traffic conditions are much more favorable in and from the southern Wyoming districts than in and from the complainant districts. They reasonably may be permitted to retain such an adjustment where they have it on the ground of competitive condition and on the broader and higher ground of public interest," he says.

Lehigh Valley Loadings

During November the Lehigh Valley R.R. loaded 1,030,067 tons of anthracite as compared with 1,124,502 tons in the corresponding month of last year. Officials of the Hazleton and Mahoney divisions of the railroad report that during the week ended Nov. 29 204,340 tons of hard coal were sent to market over those branches.

Protests Some New Indiana Rates

The Indiana Public Service Commission has announced a tentative schedule of coal rates for Indiana groups of cities in which it is revealed that the rate for Logansport has been increased $\frac{1}{2}$ ¢, to \$1.69. The State Chamber of Commerce protests the rate from Logansport, Delphi and Monticello as well as that for Lebanon, Lafayette and Frankfort, its committee having proposed that the rate for Logansport, Delphi and Monticello be reduced to \$1.50 and that the Frankfort, Lebanon and Lafayette rate be placed at \$1.50. The commission has announced the latter rate as \$1.45.

Oppose Removal of Through Rate

There has been a through rate on hard coal from the mines to the Twin Cities of \$6.56 which the roads recently sought to withdraw, effective Jan. 1. This would leave the rate the sum of the locals, an increase of \$1.66. The proposed withdrawal is being vigorously opposed by the independent retailers of the Twin Cities, who see in the move a step to force them to buy hard coal from the docks only. They suspect that it presages a further advance in the price of hard coal. The withdrawal probably will be suspended, pending a hearing on it.

G. & E. Rates Unreasonable

In an order which becomes effective Feb. 29 next, the Interstate Commerce Commission finds that rates on coal in carloads from mines on the Greenbrier & Eastern R.R. to interstate destinations are unreasonable. The order was issued upon the complaint of the Nelson Fuel Co. and others against the Chesapeake & Ohio Ry. and other carriers. The Commission also held that the rates are unreasonable to the extent that they exceed or may exceed the group rates contemporaneously maintained from branch-line points on the Chesapeake & Ohio Ry. in the New River district in West Virginia to the same destinations.

Association Activities

At a meeting of the **Northeast Kentucky Coal Association** held recently at Ashland, Ky., a report was received from the State Workmen's Compensation Board announcing an increase in the base rate from \$3.40 to \$3.75 and the minimum rate from \$2.50 to \$2.85, a flat increase of 35¢ per \$100 payroll. The increase was made notwithstanding a protest filed with the board by every association in Kentucky. The annual meeting of the association will take place Jan. 24 at the Ventura Hotel, in Ashland. A special committee was appointed by President Connor to arrange for the annual gathering, when important problems confronting the industry will be considered.

The fourteenth annual meeting of the **Smokeless Coal Operators' Association of West Virginia** is being held at Washington today. Officers are to be elected and a board of directors chosen for the new year. United States Senator David A. Reed has accepted an invitation to make an address at the luncheon following the business meeting.

Holding their semi-annual meeting during the first week of December, members of the **Huntington Coal Exchange** elected T. M. Hooper as president to succeed I. F. Vass, who has led the exchange since its organization. Roy H. Cunningham, of the Tri-State Fuel Co., was elected vice president. Other officers will be elected at the annual meeting in May. The new president is a member of the Hooper-Mankin Fuel Co., of Huntington. There were about twenty-five members in attendance at the meeting. In addition to electing officers, members gave their attention to questions of policy and discussed general coal conditions.

Coming Meetings

Coal Mining Institute of America will hold its annual meeting Dec. 19, 20 and 21 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Chamber of Commerce Building, Pittsburgh, Pa.

Tug River Coal Operators' Association. Annual meeting Jan. 4, 1924, Bluefield, W. Va. Secretary, C. C. Morfit, Welch, W. Va.

Engineers' Society of Western Pennsylvania. Annual meeting Jan. 15, 1924, Blue Room, William Penn Hotel, Pittsburgh, Pa. Secretary, K. F. Treschow, Pittsburgh, Pa.

American Wood Preservers' Association. Annual meeting Jan. 15-17, 1924, Hotel Buehlebach, Kansas City, Mo. Secretary, P. R. Hicks, Chicago, Ill.

Northeast Kentucky Coal Association. Annual meeting Jan. 24, 1924, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

News Items From Field and Trade

ALABAMA

The Thomas & Weller Mining Co., of Birmingham, has leased coal mines at Aldrich, and will use 150 convicts in operating them.

The Bryan Coal Corporation has sold 10,000 acres of coal lands in Walker and Jefferson counties to Walter Moore, president of the Pratt Fuel Corporation, and associates, who will operate present mines and contemplate further development.

ARKANSAS

At the recent convention held at Fort Smith, of District 21, U. M. W. of A., the delegates amended its constitution to debar from membership any mine worker holding membership in the K. K. K.

The Coronado Coal Co. on Dec. 4 appealed to the U. S. Circuit Court of Appeals from the decision of Federal Judge Pollock, Oct. 27 last, directing a verdict for the defendants in a retrial of the company's suit against the United Mine Workers for \$2,222,000 for alleged damages to property in the 1914 coal miners' strike. The appeal was filed for C. H. Finley, receiver for the company, with a request that the case be advanced on the docket. In support of the motion it was contended that the decision, if allowed to stand on the records, would encourage organized labor, including the mine workers, to destroy property in strikes. The United Mine Workers filed an answer opposing the motion to advance the case on the docket, declaring it was of no more public interest than others on the docket, and that Judge Pollock's decision merely put into effect previous decisions of the U. S. Supreme Court interpretative of the Sherman Anti-Trust act.

ILLINOIS

Preparations for opening up the Empire mine of the Illinois Coal & Coke Co., near the state fair grounds, which has been closed since April 1 are being made. About 375 men are employed at the shaft. Orders have been given to place mules in the mine and begin work of cleaning up. Officials of the mine did not say at what time operation will be resumed.

George A. Wilson, of Sparta, is sinking a new shaft a short distance southwest of the junction of the Mobile & Ohio and Missouri & Illinois railroads there. The old shaft of the Boyd Coal & Coke Co.'s mine will be abandoned. The new mine is the cause of litigation, resulting in a suit for \$100,000 against the Missouri & Illinois R.R., which constructed a dam creating a pond covering more than thirty acres. This may eventually wipe out a summer resort at a lake nearby, and, it is alleged, will endanger miners at work in the new mine which will extend under the pond.

After two months idleness, on account of labor troubles, the Brewerton Coal Co. at Lincoln, will reopen its shaft. Trouble over the check-weighman's scale caused the men to quit work Sept. 26.

The Illinois Department of Mines and Minerals is disturbed by politics. Since the resignation of Robert M. Medill as director, members of the staff have been uneasy because some asserted that Governor Len Small expected them to work for his re-election. Richard Neeson, a special investigator, has already resigned.

Announcement of an expenditure of \$500,000 by the Leland Coal Co., of St. Louis, on its ten or more mines in Illinois has been made. The company owns mines at Tuxhorn, Shelbyville, Auburn, Athens and Girard, besides five others in Sangamon County. The amount will be spent in various improvements at the mines.

A. J. Moorshead, president of the Madison Coal Corporation, of Chicago, is spending the month of December cruising along the California and western Mexican coast in the private yacht of his son, Oliver Moorshead, of Los Angeles. Mr. Moorshead probably will be back in Chicago about Jan. 7.

INDIANA

One of the first bills to be introduced in Congress will be one by Representative Everett Sanders providing for a federal mine-rescue station in Terre Haute, Ind. The recent disaster in the Hunt mine at Staunton, in which four lives were lost, is proving to be one of the chief points to spur those interested in the coal mines into greater activity. The entire northern region of the Indiana bituminous fields has its center in Terre Haute and the nearest federal aid is the truck station at Vincennes. Phil Penna, secretary of the Indiana Bituminous Coal Operators' Association; John Hessler, president, and William Mitch, secretary of District 11, United Mine Workers, have expressed the sentiments of their organizations as favoring the station.

The Joan Coal Mining Co., capital \$75,000, has been incorporated at Riley by George G. Rowland, David Rowland and Louis Clements.

An order naming Frank C. Gore, attorney, receiver for the Key Coal Co., was set aside in probate court at Evansville recently on motion of the Consumers' Coal Co. of Indianapolis. Gore was appointed receiver for the company on petition of Martin Emig, Jr., who alleged that the Key Coal Co. owed him \$200. The Consumers' Coal Co. asked that the order be set aside on the ground that it had filed a receivership petition four days before. According to attorneys in the case, the Key Coal Co. has issued and sold \$80,000 worth of securities with the approval of the Indiana Securities Commission.

Indiana's major coal mines produced 25,363,388 tons during the fiscal year ended Sept. 30, 1923, which was 10,413,998 tons more than was mined the previous year and which came within 3,432,294 tons of the peak production during the war, according to Cairy Littlejohn, chief inspector of the State Department of Mines and Mining. The wage paid to 31,189 miners in the major mines amounted to \$45,920,877.54, said Mr. Littlejohn. The average wage was \$1,472.32 a year. There were seventy-five fatal accidents and 6,528 other accidents during the year, with no large mine disasters. The miners of Indiana were idle 9,359 days because of overproduction, 7,814 days through shortage of cars, 459 days on strikes and 2,736 days for other reasons.

KENTUCKY

Brent Hart of the Hart Coal Corporation, Madisonville, has offered a reward of \$1,000; Governor Morrow, for the State of Kentucky, \$500; and business men of Madisonville and western Kentucky, \$800, making a total of \$2,300 for arrest and conviction of those dynamiting the home of Lee Row and Dewey Williams, non-union miners, employed by the Hart Coal Corporation. The explosion occurred in late November, but no one was injured. It followed threatening notes and placing of bundles of switches on the door steps of the house.

Hazard reports that the Himya Coal Co., at Domino, and numerous mines on First Creek, Lotts Creek, Carrs Fork, and around through the Hazard Field have closed and thrown many miners out of work.

The first coal coming into Louisville by water in several weeks arrived on Dec. 6, when as a result of rains and higher boating stages, the towboat J. F. Butts came in from the Kentucky River with six barges of eastern Kentucky coal.

An effort will be made at the January session of the State Legislature to establish a state constabulary, which would be of considerable value in handling riots and labor troubles. Union labor is expected to fight the effort.

A flood of coal taxing, coal regulating and labor bills is expected before the meeting of the Legislature in January. At the last session an appropriation of \$30,000 was made for investigating the coal situation and the taxation situation.

It is reported that Birmingham (Ala.) interests are behind the Morrison Coal Co., which is planning a stripping operation at Centertown, which will have a capacity of 5,000 tons daily. There are now some nine plants which are operating and which have capacities ranging from ten to forty cars a day, with one reported to have a capacity of eighty cars or more a day. Several additional plants are getting ready to operate.

Henry E. James, Kentucky State Inspector and Examiner, in his biennial report on the Department of Mines, Lexington, reiterates that the appropriation is far from adequate for the work. This appropriation is but \$23,800 to cover salaries and traveling expenses for nine men, including a chief and eight inspectors, and for inspection of 650 or more mines each three times a year.

NEW YORK

The Independent Coal Corporation of New York City, has been appointed agent at New York for the Naples Coaling Co., Naples, Italy, in connection with the supply of bunker coal to steamers at that port. Arrangements have also been completed whereby the corporation will represent the British Coal Bunkering Co., of Gibraltar.

PENNSYLVANIA

Negotiations are reported to be under way to purchase of coal underlying the Holy Cross Church, one of the largest in Scranton, from the Glen Alden Coal Co. The coal will cost the congregation approximately \$6,000. Thirty-five cents a ton is the figure upon which this is based, the Scranton school district having purchased coal under several of the schools at this price.

The Park Hill Coal Co., which was recently incorporated at Harrisburg, operates a slope with surface vein mining in the West Scranton residential section. Operations were started about a year ago. About 100 tons a day is the capacity of the operation.

Men experienced enough to go into the mines and cut coal are exceedingly scarce in the Wilkes-Barre region, according to statements made by several of the big producers. The operators assert that while there is more than enough common labor, men holding state mining certificates are unobtainable.

That the company has the right to prevent miners' committees from meeting on the company property; that if a committeeman or a committee calls a strike without first taking the issue before the proper body for adjudication of disputes, namely, the Conciliation Board, the company has the right to discharge the committeeman or the committee, as a whole, was the attitude announced by the Lehigh Coal & Navigation Co. at Lansford during the past week, following a strike at the Nesquehoning collieries.

Many grievances advanced by the miners' union were settled during the week at meetings arranged by the Anthracite Conciliation Board in Scranton, Shamokin and Hazleton. Only parts of the board were represented at the sessions and several of the meetings were held simultaneously in the different cities.

Assessment of culm banks for tax purposes is being made by the Scranton board of assessors this year for the first time in the history of the city. In the past the land on which the culm banks stood was merely assessed at a nominal value, equal to the figure placed against adjoining land. Next year the city will try to collect taxes on a valuation which includes both the worth of the land and the value represented by the reclaimable culm in the banks. On what basis the assessors are fixing the valuations was not made known.

To safeguard the lives of their employees and to facilitate the movement of supplies from one section of the operation to the other, the Glen Alden Coal Co., of Scranton, has constructed a 175 ft. concrete subway under the roadbed of the D. L. & W. R.R. at the Baker colliery in Bellevue. A track for mine cars has been laid in the tunnel. In the past it was necessary for employees to cross three tracks on the Lackawanna to go from one section of the operation to the other and supplies had to be hauled over one-half mile by motor truck.

The Hillman Coal & Coke Co. has resumed operations at the Griffin No. 1 plant, which had been idle for about a month, firing half of the 200 ovens at that place; the Isabella plant, which also had been idle for about a month, is firing all of the 136 rectangular ovens and half of the 124 beehive ovens.

The Husted Semans Coal & Coke Co. has fired 50 of its 195 ovens at the Husted plant, near East Millsboro, which had been idle for over a month.

The Luzerne Coke Co., a subsidiary of the Hillman Coal & Coke Co., of Pittsburgh, on Dec. 1 purchased the Orient plant of the American Coke Corporation at a sheriff's sale of the property at Uniontown, for \$45,000 cash and the assumption of the \$850,000 mortgage held by the Luzerne Coke Co., making the total purchase price \$895,000.00. The plant is located in Fayette County, between Uniontown and Brownsville, and consists of about 800 acres of unmined Pittsburgh vein coal, hoisting and air-shafts about 200 ft. deep, with modern steel tipples and equipment, and 480 beehive ovens, all thoroughly equipped. The plant has been idle for the past two or three months.

G. W. Esslinger, for the past twenty-two years chief engineer for the L. & W. V. R.R. Co., has purchased the controlling interest in the Spencer Coal Co., at Dunmore, and will take over full charge of the mine. The Spencer mine has a daily output of between 200 and 300 tons of coal and employs about 200 men. For the past three months the employees have been on strike but it is expected that the taking over by Mr. Esslinger will result in a settlement with the men and that they will return to work soon.

Coleman & Co., Inc., bituminous-coal producers, announce the removal of their offices, Dec. 1, to Banker's Trust Building, N. E. Corner Juniper and Walnut Streets, Philadelphia.

Announcement has been made by the General Committee of anthracite operators that an "anthracite economy show" is to be opened in Philadelphia and maintained on a "more or less permanent basis." The show was organized by the committee, it was stated, acting in co-operation with the makers of apparatus for burning the smaller sizes of anthracite. Nine or ten manufacturers of such equipment will exhibit. Information for all anthracite users will be available, it was announced, experts representing the manufacturers being reinforced by fuel engineers connected with the producing companies.

Coal must be sold by the weight and not by the load in Hazleton, according to an opinion from the State Department at Harrisburg. City Inspector of Weights and Measures James P. Lamont, of Hazleton, found coal being sold by the wagon load in some parts of that city.

West Nanticoke Coal Co., through its president and secretary, A. D. W. Smith and Carl B. Metzger, has filed a petition with the Luzerne County Court, asking for a dissolution of its charter. A hearing will take place December 31.

Rinaldo Cappellini, president of District No. 1, United Mine Workers, has been elected delegate to the international convention of the United Mine Workers of America in Indianapolis, Ind., in January, to represent the No. 6 colliery local of the Pennsylvania Coal Co. The district president is a member of the local.

Considerable business is coming to central Pennsylvania coal operators, notably in the Broad Top region and in Somerset County, by making bituminous coal available as a substitute for anthracite. Operators are installing breakers and screens to prepare the coal in suitable sizes, corresponding to the sizes of anthracite. In Somerset County, the E. E. Sheets Coal Co. has purchased the coal property a short distance southwest of Somerset, for many years operated by Wesley J. Barron and later by his son Ira Barron. Recently a deposit of cannel coal was opened up on the property and it has since gained such strong favor in the markets of the East that the entire output has been contracted for by a Baltimore dealer. Local consumers of the fuel are using the smaller sizes which result from breaking and screening, being unable to secure a supply of the larger sizes by reason of the contract with the Eastern dealer.

The U. S. District Court at Philadelphia in a decree signed by Circuit Judge Davis Dec. 4 appointed the Wilmington Trust Co., Wilmington, Del., as trustee of the stock of the new coal company which is to be organized as part of the plan for the dissolution of the Reading Company and its

underlying subsidiaries, under orders of the U. S. Supreme Court. At the same time counsel for the Reading companies revealed that the new corporation is to be organized under the laws of Delaware and will be known as the Philadelphia & Reading Coal & Iron Corporation. A warrant showing the right of stockholders to subscribe to certificates of interest in shares of no par value of the proposed new Philadelphia & Reading Coal & Iron Corporation, will be delivered on Jan. 10 to stockholders of the Reading company, Jay V. Hare, secretary of that company, announced Dec. 6. The warrants are to be issued to shareholders of record at the close of business Dec. 17. This procedure was ordered in a resolution adopted by the Board of Directors.

William H. Patton resigned Nov. 30 as district sales engineer, in charge of the Pittsburgh office of the Ironton Engine Co., with which he had been connected for the past five years and eight months.

TENNESSEE

An early morning fire Nov. 14 destroyed the commissary store of the Fork Ridge Coal & Coke Co., Fork Ridge, Delsea, just south of Middlesboro, Ky., resulting in a loss estimated at \$50,000. Lack of wind made it comparatively easy to prevent spreading of the fire and loss of the town. Two residence buildings were burned.

VIRGINIA

Hugo Stinnes, Jr., son of the German industrial king, was in Norfolk recently in company with T. J. Licklider, manager of the Norfolk office of the Lake & Export Coal Co., agents for the Stinnes ships. Stinnes came from Charleston, W. Va., where he inspected coal operations, and looked over the coal-handling facilities at Norfolk. Mr. Licklider said Stinnes was following coal from its source to tidewater to study methods used in handling it. He went from Norfolk to Baltimore to watch the operation of piers there.

The Board of Directors of the Virginia Iron, Coal & Coke Co. on Nov. 22, declared a dividend of 2½ per cent on the preferred stock, and a dividend of 1½ per cent on the common stock, payable Jan. 2, 1924, to stockholders of record at the close of business Dec. 15.

WASHINGTON

The twenty-eighth winter mining session of the College of Mines, University of Washington, will be held at Seattle from Jan. 4 to March 20, 1924. The courses are open without examination to anyone interested in mining. Expenses consist of the cost of materials actually used and a university fee of \$20. The studies are arranged in four groups: quartz mining, placer mining, coal mining and ceramics.

WEST VIRGINIA

President J. B. Clifton, of the Raleigh Smokeless Fuel Co. and of several other large operating companies in the Winding Gulf field, with headquarters at Beckley, sailed Dec. 6 on the ship "Southern Cross" for South America to visit the company's agency at Rio Janerio and other points in South America. He expects to be away for several weeks.

One of a series of meetings of mine inspectors to be held was concluded on Dec. 5 in the office of R. M. Lambie, chief of the state Bureau of Mines, at Charleston. Problems confronting the West Virginia inspectors and methods with which to meet them were discussed. Other meetings will be held at Fairmont and Welch. A two-day examination for foremen and firebosses of this district, in which seventy-two candidates had entered, also ended the same day.

The Gage Coal & Coke Co., operating at Junior, Barbour County, is engaged in constructing a river conveyor which will enable the company to dump coal on both sides of the Tugarts Valley River.

The D. T. S. Coal Co. has increased its capital stock from \$100,000 to \$250,000; the Holly Elk Coal Co. from \$200,000 to \$350,000; Pinnacle Coal & Coke Co. from \$500,000 to \$750,000; Middle Fork Block Coal Co. from \$150,000 to \$200,000. The capital stock of the Elk Ridge Coal & Coke Co. has been reduced from \$75,000 to \$25,000.

There were ten new coal companies launched in the state during October, eight

of them resident and two of them non-resident coal corporations, with an aggregate capital stock of \$4,750,000. The largest was the Mansfield Coal Corporation, of New York City, having an authorized capital stock of \$3,500,000. Other companies organized included the Columbus Pocahontas Coal Co. (non-resident) of Columbus, capitalized at \$500,000; Cap Smokeless Fuel Co., Charleston, \$75,000; Wheeling-Glenwood Coal Co., Wheeling, \$50,000; Jaunds Mining Co., Charleston, \$130,000; Royal Pocahontas Coal Co., Iaeger, \$20,000; Cagney Coal & Coke Co., Fairmont, \$25,000; Bellis Coal Co., Buckhannon, \$25,000; La-Go Pocahontas Coal Co., Iaeger, \$100,000, and Gibraltar Coal Co., Charleston, \$325,000.

A suit instituted in the Circuit Court of Marion County by S. A. Scott, an operator of Fairmont, against W. W. Brewer, Ed Baker, Bruce Davis, Ervid Right and H. H. Harrison, partners trading as the Stone Lick Coal Co., involves approximately \$300,000, the largest amount of money in litigation in Marion County in several years. The plaintiff claims breach of contract on the part of Brewer and his associates in not permitting Scott and his employees to operate a tract of coal of about 600 acres in the Lewis County field under the terms of a contract in existence. The plaintiff bases the amount involved in the suit on the profits which he claims could be made on the tonnage mined from the tract. Another action has been brought by C. W. Brandon against Brewer and his associates, in the sum of \$10,000, Brandon claiming that he carried on the negotiations which would have permitted Scott to mine coal from the Lewis County tract.

WISCONSIN

Low water in Lake Michigan is troubling coal men because large carriers are unable to load to capacity and reach docks at receiving ports. This is particularly true of Milwaukee. The leading dock companies of that port have petitioned the municipal authorities to provide increased funds for dredging harbor channels.

Four steel steamers belonging to the Cleveland Cliffs Iron Co. are being equipped with self-unloading machinery at Sturgeon Bay. It is designed to use the vessels in delivering coal to ports on the upper lakes where docks have no unloading bridges.

CANADA

At the annual meeting of the United Boards of Trade and Chambers of Commerce of Western Ontario at St. Thomas, on Nov. 29 a resolution was adopted urging the Dominion and Provincial governments, the Canadian railways and all others concerned to endeavor to make it economically possible for the people of Ontario to use Alberta coal, to prevent the recurrence of the shortage experienced during previous winters.

Overproduction is given by H. B. Gillis, superintendent, as the cause for the suspension of operations at the Bell Island mines of the British Empire Steel Corporation. The mines closed on Nov. 30, about 1,000 men being thrown out of employment. Only sufficient help will be kept on to keep the mines pumped and the power house in readiness for resumption of operations, which it is hoped will be about the middle of January.

One of the outstanding events of a week ago from the viewpoint of coal-mine operators and employees was the announcement in the budget speech of John Hart, Minister of Finance, to the Legislative Assembly of British Columbia, that a tax of one half cent a gallon would be placed on foreign fuel oil consumed in that province. This is a policy that has long been advocated by William Sloan, Minister of Mines, who represents the coal mining town of Nanaimo, Vancouver Island, in the Legislature.

Over three million tons of coal was produced by the Dominion Coal Co. during the eleven months ended Nov. 30, according to figures obtained last night. The output for November was 205,658 tons, which is the smallest month's tonnage since April, 1922, when a strike on the job policy resulted in curtailing the monthly output to 162,085 tons. The actual figures for the first eleven months of this year are 3,071,159 tons, compared with 2,558,293 tons for the same period in 1922, an increase in 1923 of over half a million tons. The November output is some 88,434 tons less than the October tonnage and 111,212 tons less than that for November, 1922.

New Equipment

New 5/16-Inch Portable Electric Drill

This portable electric drill with a capacity up to $\frac{5}{16}$ in. in steel is quite similar to the $\frac{1}{4}$ in. drill, but has a much more powerful motor and other parts in proportion to its size. It is equipped with a three-jaw gear nut chuck for straight-shank drill bits. It weighs 7 lb. and has a no-load speed of 1,400 revolutions per minute. It is equipped with the well-known pistol grip and trigger switch.

The Black & Decker Co., Towson Heights, Baltimore, Md., now have this tool in production and expect to be ready soon to make deliveries.

NEW PORTABLE ELECTRIC DRILL

Drilling the work on the job instead of carrying the work to a drill press is possible on many jobs where this drill is supplied.

Single-Speed Bench Lathe

A new single-speed portable 6-in. bench lathe has been placed on the market by J. D. Wallace & Co. This machine, which probably is the smallest electrically driven woodworking lathe made, is designed to do the smaller turning operations which make up a great share of the work in many woodworking plants.

This little lathe is intended for work up to 6 in. in diameter. It clears 5 in. over the tool rest and 7 in. on the faceplate, with full 24 in. between centers, and runs at 3,400 r.p.m. The machine weighs but 203 lb. and at the same time it is heavy enough to stand rigidly without vibration. Its height over all is 46 in. and length over all 40 in. The sub-base is open, so that it serves as a convenient holder for tools.

A $\frac{1}{2}$ -hp. ball-bearing motor is built into the headstock and is entirely enclosed, making it dustproof. It is

MOTOR-DRIVEN BENCH LATHE

This little bench lathe is designed for work up to 6-in. diameter and is supplied complete with electric motor drive.

direct-connected to the lathe spindle and provides ample power for cutting up to the limit of the lathe. It is controlled by a conveniently located switch, and as there are no belts to shift, the safety element is well taken care of.

Double Drum Hoist for Slushing

The tremendous increase in demand for metals, coal and other products of the mine has caused the application of mechanical methods to one mining operation after another during the last half century. The drilling of the rock and its transportation are now done in several efficient mechanical ways but the handling and loading of the material broken in the underground workings is still almost universally being done by hand.

The inefficiency of the hand shovel and the increasing scarcity of the class

of laborers required for the work have led to the development of a number of loading and shoveling machines, many of which are successful in the class of work for which they are designed and adapted. Machines of this class now on the market are practically all large, heavy and of high capacity. They require the services of operators of a higher grade of mechanical intelligence than is common among ordinary mine labor. In addition to high first cost, many of them frequently require expensive and time-wasting repairs. Furthermore, their size, weight and capacity limit their adaptability to utilization in the larger openings and most accessible places.

An excellent solution to the problem lies in the use of the 6-H "Little Tugger" air hoist with a scraper. The method is called "slushing." The use of scrapers in mining merely involves the application of the several arrangements that have long been widely used in surface operations, varying from the horse-drawn slip scraper, or "slusher," seen on every small grading job to the various dragline scrapers and graders used in ditching, grading and other large excavation work.

The 6-H "Little Tugger" hoist is small enough to work in narrow drifts or crosscuts and under very low heading. It is sufficiently powerful to load any muckpile. It is simple enough to trust to an unskilled workman. It is so rugged that it will continually stay on the job without needing any expensive time-wasting repairs.

The small size, portability and ease of mounting the "Little Tugger," allows it to be quickly moved. As it can be set up almost anywhere—it can be clamped to a column, bolted to a timber or mounted on a truck in a few minutes' time—it usually is unnecessary to make any rearrangement of chutes, crosscuts or rooms to effect a marked saving in mucking and loading time and labor.

This hoist was specially designed for slushing, but there are many other jobs to which it can be successfully applied, such as balanced haulage in mines and strippings. The Ingersoll-Rand Co. are the manufacturers.

DOUBLE DRUM AIR HOIST

Within the next few years one of the greatest developments in coal mining probably will be in the application of labor-saving devices at and near the coal face. This little air hoist, being portable, can be used for scraping in many rooms.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

Volume 24

NEW YORK, DECEMBER 20, 1923

Number 25

Investment Engineering

COAL-MINE electrification has been rapid, its economies have been real and amazing; yet much has been done with a blind faith in the savings to be realized. Greater advantages are still possible. Many mines have only begun to electrify their machinery and install new labor-saving, high-efficiency, lower-cost-per-ton equipment. Mining companies which believe themselves completely electrified today will find themselves making new applications in the next few years. Again, since this type of equipment is out of date in from ten to eleven years, there are continuous big engineering and financial problems to solve each day.

Thus we find the financial questions involved in making a coal mine modern loom larger and larger. It becomes increasingly more necessary that the engineer better understand the investment side of his business; he must do his engineering from the financial point of view and ably present to his company executives his engineering proposals, which are sound only as they are founded on lower cost, safer coal production.

Herbert Hoover recently said: "The function of the investment banker is to find the money for the advancing of equipment of the nation. As science advances, it is the duty of the engineer to lead its promises up to the investment bankers." Here we have the urge upon the banker and the coal-company engineer. How can these big forces be brought together? A part of the answer lies in a better understanding of investment problems on the part of the engineer.

Wage Competition

ALREADY there is bitter complaint on the part of groups of operators paying the union scale of wages in the soft-coal fields that they are not able to compete with non-union coal at lower wages. It is a rumbling such as preceded the war of 1922 in these coal fields. It is difficult to understand how the comparatively small amount of wage reductions that have taken place in the non-union fields could have made the situation so acute as some profess to find it. The large groups of non-union operators are holding fast to the high scales; those making the reductions are small and relatively few in number, mainly, it appears, in Somerset and eastern Kentucky.

There are none so blind as those who will not see and such are those who blame all their lack of ability to sell on underpriced non-union competition. There is little statistical basis for such an alibi as yet, but how much stronger the disclaimers will be next spring if costs are really hacked down in southern West Virginia as in 1921-22!

And if the non-union producers can and do later on cut their costs by reducing wages, it will be because they can. The union operator who harbors any idea that he can by hook or crook, by any device or strategy

gain the consent of the United Mine Workers to a reduction in the scale next spring is fooling himself. The organized soft-coal industry is plainly faced at best with a continuation of the present scale. We say *at best* advisedly, for the treacherous 10-per cent that Pinchot handed to the hard-coal miners, by common consent, darkens even that prospect. The most ill-advised move possible is for any group of union operators to commit themselves to a demand for a wage reduction next April. There is not the slightest sentiment in business today for an attempt to deflate coal wages at the expense of another 1922.

What is the answer then? If it does not lie in endless, pointless damning the other fellow it must lie in earnest seeking to get the union coal-mine worker to *earn* the high wage he now gets. If the problem of the coal operators were markedly different from the operators in other industry, then we might conclude that the coal producers were alone at fault, but that is not so. Organized labor the country over still feels its oats and is unitedly in opposition to any reduction in its war and post-war wage rates.

Trade-Commission Policy

JUST what the Federal Trade Commission hopes or expects to gain other than free advertising by its series of reports on anthracite prices is not clear. The statements are as misleading now as when first issued, for they stress the insignificant minority of premium-priced anthracite and glide over the normal priced majority. The institution of this series drew its inspiration from the White House. The President, it was reported at about the time the Coal Commission ceased to function, believed that the hard-coal trade needed airing, and to the Federal Trade Commission was assigned the mopping up job. The idea of the Federal Trade Commission always is to pick a culprit and roast him on a spit. The commission has not even the finesse of Pinchot, who before he launched his attack approached the anthracite operators with a proposal for lowering the retail price; a proposal that was illegal and therefore rejected.

American business has long since foregone the thought that the Federal Trade Commission has any intention of being helpful; the coal industry has come to expect it to be unfair. Whatever be the personnel of the Commissioners, the staff is the fountain head of ideas and inspiration for business-baiting prosecution. We have no criticism of the Trade Commission for proceedings instituted in respect to unfair trade practices, if and when the cases are instituted on some reasonable grounds. It would be the people's protection against high coal prices, or any coal prices, perhaps. But that is not all the Trade Commission indulges itself. Advantage is taken of every opportunity that affords to assail coal. These anthracite reports are but bi-weekly re-

hash of the same old story, without the critical discussion offered by the Coal Commission when it gave the same material to the public.

Is it the idea of the administration that such material will serve to lower the price of coal; that this is publicity that will tranquilize the market; that the Trade Commission is helping the industry, the government or the public by broadcasting the already well-known fact that some anthracite is sold at higher prices than the remainder, when the market will take it at those prices? Has advertising reduced in any way the volume of speculation on Wall Street or in Chicago on grain, or in Louisville on horse races? The margins of the middleman handling anthracite may be speculative, and away above normal, under certain market conditions. The Trade Commission is not simply giving publicity to that fact, but is seeking to establish a public opinion contrary to any free trade in coal. The Trade Commission wants the distribution of coal put under its supervision.

Function of Presidents

WHAT is the function of the president of a coal company? By that we mean not what he does but what he ought to do. Judging by experience of presidents as a class, they are principally interested in the "politics" of the coal industry and the selling of coal after it is produced. Exceptions there are, especially in some fields, and incidentally it may be remarked that they are among the best and most progressive of operators. Too many executives are today interested solely in the strike question, in sales, taxation and federal regulation.

For all their activities, the operators—the bituminous operators at least—have organizations; for strikes, their operators' associations; for sales, their sales organization; for taxation, their accounting department and taxation experts; for federal regulation, their National Coal Associations; for production, their field force. Consequently when well organized their business should conduct itself.

But somehow they grant that so-called autonomy only to the field force, and they busy themselves with the other activities, for no other reason apparently than that they are urban and do not require them to subject themselves with their urbanity to the discomforts of the mining town, the mine boarding house and the underground.

But is the field force autonomous? By no means. It is ruled with an iron hand. It may do almost anything so long as it produces cheap, salable coal and does not demand any expenditure of capital. Consequently, usually no experimenting and no purchases of new forms of equipment are permitted. The progress of invention passes along unheeded until some enterprising and real president adopts it, economizes thereby or makes better coal. Then at last the president of the average company gets interested and arranges to get what he should have had long ago. Or perhaps an explosion occurs and the field force gets co-operation as to constructional funds and operating expenditures that will make such hazards less menacing.

Many mine managers fear to advise the purchase of additional machinery or the inauguration of conservational or safety measures likely to show on the monthly cost sheet. They would seek co-operation from the president if he knew more than the one word "No."

The Future for "Too Many Mines"

TIME has a way of creeping up and catching some folks unawares. Time caught up with the overdeveloped anthracite industry of two decades ago. Time, smooth flowing time, easing from one year of trouble to another year of quiet, has brought the hard-coal industry a new set of troubles. None will say that having solved, at great cost and long effort, the problem of "too many mines" the hard-coal men are not up against other and as difficult problems.

Depending on who does the guessing, estimates of overdevelopment in soft coal range from 25 to 100 per cent. We all recognize that the bituminous-coal industry is treading the mill over which the anthracite industry passed a decade or so ago. Development of the anthracite mines was checked; demand has overtaken production, putting the business on a profitable basis, as it should be. But being thus, new problems have been presented, serious because becoming acute in a period of general economic unrest and positive union-labor control.

And is the bituminous-coal industry about to profit by the lessons in anthracite? Much is different, but much is similar in this aspect of the two industries. There is definite push from the public—President Coolidge voiced it in his message—for consolidations in the soft-coal industry. The country is growing; it will not require long for consumption to overtake the productive capacity of all soft-coal mines that are at least reasonably efficient. It were well that the soft-coal industry look back over anthracite history and think ahead in soft coal to that time when "Too many mines" is a thing of the past. The problems of the future will be different from those of today.

Judge Gary is a forward-looking man—one reason why he heads the Steel Corporation. He recently said: "There are no substantial grounds upon which to base a thesis that in America the productive capacity of the country as a whole is in excess of the ability of the people to consume, and it is a sound business policy to build on the theory that consumption will continue to increase. The growth may be irregular, with innumerable waves; but these are of much less importance than the fact that over a period of years there is always a substantial increase. A man can provide against temporary depressions but cannot take advantage of increases in demand unless as a matter of business policy he has built up liberally his productive machinery."

It is all well and good to stem the tide of overdevelopment of coal but there must be no overlooking of the problems of the future such a program entails.

"IT IS NOT THOROUGHLY UNDERSTOOD in Washington why Governor Pinchot is insisting upon outside regulation of the anthracite industry when the State of Pennsylvania can do under its own power everything that he suggests. There are those who believe that the only way to meet the anthracite situation is to authorize a combination which will include all mines producing that type of coal in Pennsylvania."—*News Note*. That is just what Mr. Warriner said in his academy speech last month—"Certainly it is not sound public policy to transfer from experienced managers to the political arena the regulation and control of this industry until the managers have been given an opportunity to try and work out their problems under laws which permit collective action and self-correction."

Safety Stunts Help Miners Protect Themselves

Reminders Should Be Unusual and Striking—Freshen Up the Bulletin Board with Drawings of Accidents at Mine at Which They Occur—Warning Cards in Pay Envelopes and Premiums for Foremen Also Help

"HOW can we make men protect *their own* lives?" It is an old lament. The Midwestern coal operator who gave voice to it as he scanned a fresh report of a fatal accident in one of his best protected mines is only one of thousands of conscientious employers who have wagged their heads helplessly over this puzzle of the age.

Miners are just like other workers. They do grow callous to danger—their own danger. No matter what their instructions, there are always a few who *will* open a can of powder by driving a pick point into it. No matter what the boss says, there are always a few who *will* be reckless with electricity. No matter about the instructions, or the boss, or common sense itself, there are always a few who *will* strike a light where gas may lurk.

"You can't get away from it," declares a safety engineer; "there always will be careless miners and there always must be a campaign for safety going on, no matter how discouraging an occasional case is, here and there. The more safety work is done, the more lectures are delivered, the more signs are posted, the smaller will grow the number of serious accidents. That is proven by comparative statistics covering recent years. Operators must carry on general safety work all the

time, and then, on top of that, they should be forever striving to find new, fresh, striking ways to make the miner 'think safety.' The old tricks do grow stale with time."

Keeping the thought "safety" fresh in miners' minds is an art that gets a good deal of attention in many mining companies. R. M. Lambie, chief of the West Virginia Department of Mines, told the Mine Inspectors' Institute of America something about it at the last Institute meeting. In Mr. Lambie's state, there are several large companies whose effort along safety lines bears abundant fruit, and "stunts" of one sort or another are part of the effort.

SAFETY WORK PREVENTS MANY ACCIDENTS

Since 1917 safety work has been more at the fore than it was previously. Statistics prove that it has paid. In 1917 West Virginia mines employed 95,883 men and in 1921 the figure rose to 124,576, but the number killed dropped from 394 to 346, which means that only one life was lost for every 338 men employed instead of one for every 225. These figures mean something. Somewhere there was a sound reason for this saving of lives.

One reason was the marked shift from black powder

to permissibles. Between 1917 and 1922 the quantity of black powder consumed dropped off 253,383 kegs, which is a vast quantity of dangerous explosive. Permissible powders increased 1,183,777 lb. in the same six years, which had a good deal to do with reducing the number of lives lost by explosion. Explosion fatalities at Davis Coal & Coke Co. mines were reduced 75 per cent. In 1922 the state produced 232,000 tons for every life lost inside the mines. The annual average since 1883 is only 187,000 tons. Something is responsible for this great change for the better. It must be the safety work.

There are plenty of facts to prove that the mines in West Virginia in which safety is actively taught are least afflicted with death. For instance, though the state's total tonnage per fatality last year was 232,000, the Consolidation Coal Co.'s record is 749,600! Other companies also can show proud records. But the state is full of lesser mines where the words "Be Careful" are not so often dinned into miners' ears, and where safety precautions are not so prevalent. These pull down the average. Mr. Lambie's state is striding forward every year, however, and the work of the chief himself and his crew of state inspectors is an important reason why.

But what are some of these "stunts" used in West Virginia to make men "think safety"? Every one of them is aimed to awaken within men the knowledge that after all is said and done, after the company has installed every known protective device, after experts have sounded every possible warning and given all sorts of instruction, a man's safety depends only 20 per cent on all these and 80 per cent on himself.

One "stunt" has to do with pay envelopes. Every man takes a personal interest in what that particular envelope contains. In one company, if any official or miner is observed to disregard the usual safety rules or is known to have done so at any time during the preceding pay period, a card with red ink on it appears in his envelope, stating just what he did, and when and where he did it, and is signed by someone in the safety department. The reverse side of the card says: "Remember—safety first. Never again be the cause of receiving a similar card, but ALWAYS BE CAREFUL." The chances are the reminder in that pay envelope goes with that man through many a week to come.

A 3x6-in. tag plays a part in one big company's safety work. That company keeps careful safety statistics on the accident record of each of its mines. Each

Result	J. H. Flaherty Safety and Efficiency Department

A WARNING IN THIS MAN'S PAY ENVELOPE

Alex Markov was observed entering a new working place without properly testing the roof. He got this card, with some of its message printed in red, warning him that he had disregarded "the usual safety rules that benefit you, your family and fellow-men." Perhaps he was a safer man after that.

C. W. & F. ACCIDENT PREVENTION BULLETIN NUMBER 5

The miner in the picture below has gotten into a manhole to let a trip pass so that should the motor or a car jump the track, he will not be hurt.

Always get into a manhole when you see a trip coming, but before stepping out again look for the rear marker or rear light to make sure that the trip has not come uncoupled. Also look back to make sure a second trip is not following the first. Many men have been killed or severely injured by run-away cars following a trip, or a second trip following the first.

ANOTHER SAFETY NOTE IN THE PAY ENVELOPE

An Illinois mining company uses a series of these safety lessons on small sheets stuffed into the envelopes once a month for several months at a stretch. Then there is a lapse of time before the next burst, for it will not do to overwork even a good idea lest it get stale.

month some mine is unfortunate enough to have the worst record for accidents. Immediately that mine is all afficker with the 3x6-in. tags attached to cars, signboards, timbers, headframe, wash-house door—everything about the mine. The tags are printed in green, showing as their outstanding feature a big hand in a circle.

"Safety First," the old, old slogan, is on the palm of the hand. On one side the tag says "You are Judged by The Company You Travel In. Travel With The Safety Men; It Means Your Happiness and Safety." The other side says: "Do Not Remove This Tag. It Is Here for a Purpose." And every man in that mine knows what that purpose is. The tags remind them of that purpose for thirty days, or until they remove their mine from the "worst" proposition on the company list. Then all the tags are removed.

Cash is another weapon against accident. It may seem a doubtful policy to pay men to protect their own lives, but when that pay goes to foremen and assistant foremen who are directly in charge of the performance of men on the job, the objection is largely removed. These officials are being paid for protecting others—not themselves. After all, nothing speaks louder than good American dollars, so a premium system is used in one of the great coal mining companies' system of mines under which foremen can add as much as \$25 and assistant foremen up to \$15 a month to their pay.

In order to qualify for premiums, foremen and assistant foremen must not miss more than one working day in the month, they must have received and receipted for a copy of the company's "Synopsis of Instructions" on safety and they must have been examined by the company physician to prove their own physical condi-

tion. Also in order to collect the premium each one must have less than ten demerit marks against him. He gets ten demerits if during the month any man under him suffers a minor injury (causing the loss of seven days or more), twenty demerits for each serious injury and forty demerits for each fatality.

If a company inspector finds any dangerous condition existing in an assistant foreman's section of a mine, that assistant foreman gets five demerits, but the assistant foreman wins five merit marks for each month in which no dangerous conditions are found, and five more are credited if there are no accidents. Thus the man has a chance to wipe out his demerits. The foreman's account is charged with all demerits and credited with all merits of the assistant foremen under him.

An added premium for long-time safety service is provided in this clause of the premium rules: "Any mine foreman or assistant foreman who for six consecutive months is entitled to the monthly premium of \$10 or \$5 will, at the end of the sixth month, receive a special premium of \$15 or \$10 and for each month thereafter so long as his record is up to the requirements; but when his record does not come up to the requirements he again will have to make a clear record for another six months before he is entitled to a special premium."

KEEPING "PUNCH" IN THE BULLETIN BOARD

That old stand-by, the bulletin board, does its bit for safety at many a mine. The problem is: What should be put on it that does not get stale, that keeps the board forever interesting and that will put over the lesson of safety with punch?

One device is a picture of every accident. This does not mean a photograph. It means a blueprint drawing of just what happened, where and how, as viewed both from the side and overhead. These two drawings on each such blueprint tell the story even to a man who cannot read the description of the accident which is printed at one side. There is human interest in such sheets, and it is enough to draw a lot of attention to the mine bulletin boards.

A similar idea in the use of pictures on the bulletin boards is embodied in the plan of the Chicago, Wilmington & Franklin Coal Co., in southern Illinois. The names of the principals in each accident are not used, but whenever an accident of major importance occurs, it is described in a series of pictures drawn by company home talent on a single big sheet. This is posted at all mines.

For instance, a man loses a foot by using it to open the knuckle on a freight-car coupler as he was coupling up a string of empties. The artist draws four pictures. The top one shows the unfortunate man signaling for the cars to be shoved together. The second shows him trying to open the knuckle with his foot. In the third drawing, he is lying on the ground with his foot crushed in the couplers of the two cars and the last shows him extricated, minus a foot, surrounded by stretcher bearers and first-aid men.

"This accident, which occurred at our mines Feb. 10, 1921, could have been avoided if the coupler had been doing his work in the right way and had taken proper precautions. Better be safe than sorry. Use the proper methods!" says the type matter on the bulletin.

News interest is worked into blueprints for the boards at the United States Coal & Coke Co. mines

in West Virginia and Kentucky. The company posts at the end of every month tables showing the safety standing of every mine. Comparisons are made with previous months and previous years so that a miner may know exactly where his own mine stands in the list and whether it is improving or slumping.

To keep the bulletin board ever changing, messages of all sorts are pinned up from time to time. "The wife of a careless man is ALMOST A WIDOW," says one, and it is a line which is not easily forgotten. Another was inspired by the game of "Put and Take." On a blueprint sheet were drawn six pictures of put-and-take tops, each showing one of the hexagonal sides of the top with its inscription "Put two," "Take one," "Take All," and the like. Each inscription was worked into a sentence thus: "TAKE ALL precautions for your safety," "PUT TWO hands on the hand bar when in the cage," "TAKE TWO knocks on the roof before you start work," "PUT ONE prop up before you TAKE ONE down," and so on. Another blue sheet says: "The only safety appliances which this company cannot furnish for YOUR protection are eyes that see and brains that think. They are the best safety devices known. USE them."

DON'T "NAG," ESPECIALLY ON A BULLETIN BOARD

There is plenty of safety service that mining companies can get out of the bulletin board; but how many of them make the board a live, appealing thing which grips men's attention? How many of them permit it to get all cluttered up with stuff of all sorts that distracts rather than attracts attention? How many of them put it in the right place and give it light enough? How many of them keep the board fresh and new? The National Safety Council spreads some good ideas about bulletin boards.

Three things every safety bulletin ought to do, or it

Survey made by	<i>W. B. Hendley</i>

Note: Steve Deikolo was shoveling coal into a car when a piece of slate fell from the rib, struck Deikolo and broke his back.

AN EFFECTIVE WAY TO TEACH A SAFETY LESSON

The whole story of how Steve Deikolo's back was broken by a chunk of slate falling on top of his head is told in these two home-made drawings and the information entered in the blanks at the left. The poster does not need to say that it is dangerous to begin loading out coal from a freshly cut and shot place without making sure that there is no loose top or overhang. Every miner reading the bulletin gets the lesson.

C. W. & F. SAFETY BULLETIN

This accident, which occurred at one of our mines February 10, 1921, could have been avoided if the coupler had been doing his work in the right way and had taken proper precautions

Better to be safe than sorry; use the proper methods

HOME TALENT OFTEN MAKES THE BEST POSTERS

This picture story, showing how a certain man in the employ of the Chicago, Wilmington & Franklin Coal Co. lost a foot, was posted on all the bulletin boards of the company just after the accident, when its message might have the deepest effect upon the rest of the company's men. Great expense is not essential to the making of good safety bulletins.

is not worth posting, the Council says. It should stimulate safety thinking, create good will toward safety work and warn miners against unsafe practices. The whole

bulletin should be such that it can be read at a glance—or practically that. Picture and text must be vivid and directly to the point. The bulletin must aim to get over just one idea.

Directness, however, does not mean telling readers bluntly just exactly what you mean. It is more effective to frame the message in such a way that the reader infers its meaning. For instance, if a man has been hit on the head with a sledgehammer head that flew off the handle, the bulletin based on this accident should not say "Don't use loose-handled sledges" and let it go at that. Better, it should say, "Nobody has ever been smart enough to think of a good excuse for using a sledge with a loose handle; there isn't any." The reader must make a trifling mental effort in order to get the lesson. For that reason, he remembers the lesson longer.

Another thought for bulletin makers is: Don't harp continually upon the word "careless" lest the miner eventually get sore. Bulletin results will thus be made less effective. Also it is generally accepted nowadays that revolting pictures of accidents are not good because they tend to scare a man instead of instruct him. Instilling perpetual fear within a man does not necessarily make him safe. Rather it reduces his efficiency and makes him flighty and more likely to have accidents. Therefore good safety bulletins should be positive in tone rather than negative.

"Put a good man in charge of bulletins," says the Safety Council. "Let him strive always to make his bulletins as local as possible. Free use of his own camera is always a good thing. He will want the bulletin board in some place where men congregate rather than at some gate where they merely stream past. He will keep changing everything on the board from day to day and he will put very few things on at a time. If he learns a few of the main principles of advertising display so as to be able to make each bulletin an attention getter, if by no more complicated an expedient than the proper drawing of a heavy line or two or the skillful use of a piece of colored crayon, his service will be of greater value."

Good bulletins and cards and pay-envelope stuffers—devices like these are answering, in a way, the lament of the operator who wonders how to make his men protect their own lives. There are scores of other special methods, all backing up the basic safety work of instruction, and each fresh crop of "stunts" helps make men "think safety." When miners do that, accident rates drop markedly.

Compiled by Ore & Coal Exchange, Cleveland, Ohio; H. M. Griggs, manager.

What Will It Cost? What Will It Earn?

BY CHARLES M. MEANS
Consulting Engineer, Pittsburgh, Pa.

THE engineer of today must solve business problems as well as those pertaining to engineering. In this article Mr. Means tells the engineer how to arrange his report, revealing important points in presenting a proposal and in setting up the engineering data.

ELECTRICAL engineers employed by coal companies frequently make reports intended to show the value of proposed changes or extensions to the electrical system. The report is carefully made up and submitted to the particular officer responsible for expenditures and quite often the engineer is not further advised as to the outcome, in which case he naturally feels that his work has not been appreciated.

In the course of my work I have had occasion to review many such reports and a considerable number were so arranged as not to admit of an analysis except by an engineer. There are only two questions that are really important to the official responsible for finances and these are: How much will it cost, and what will it earn? Anything else is subsidiary to these two items. If the answers to the above questions are hidden away in a mass of figures and calculations they may mean very little to one not familiar with engineering problems. If the change under consideration is one where monetary gain is a considerable item and it is shown clearly in the report, the official responsible for results cannot afford to allow it to lie quiescent as he never knows when it will return to haunt him.

I have had occasion to make up reports on existing or proposed electrical systems for more than a hundred properties throughout the country and have had ample opportunities to observe the reactions from the various arrangements of data compiled.

RECOMMENDATIONS SHOULD SUIT CONDITIONS

It is important that all information be obtained as to present operating costs and how they are incurred, all engineering data having a bearing on the problem under consideration, together with a complete personal examination of the existing local conditions and a careful study of the personnel of the organization. It might seem that a study of this last item is not essential, but in reality it is fully as important as any other phase. It is economically wrong to recommend any arrangement that cannot be successfully handled by the men employed at the mine. It is infinitely better to install equipment that the present employees can operate than to try to get new men.

With all data available, the problem of the engineer is to work up a report showing clearly all the details of the proposed changes. Herewith is shown a table of contents (Fig. 1) which appears as the first sheet of such a report. The next sheet is a short introductory statement outlining what the report is intended to cover. The following sheet (Fig. 2) is really the first page of the report and contains all the essential information that is required by a board of directors.

The first item may cause quite a shock to the board members, but they are in much better spirits to recover

from it than if they had been required to read through the entire report before arriving at the final figure. The second item has a rather soothing effect and by the time the members reach the subsequent figures on the page they are fully reconciled to the apparent high first cost. The figures shown on this page must be supported by thoroughly reliable data and calculations appearing on the subsequent pages.

Inasmuch as a report such as described is intended for those responsible for the financial investment and returns, it is essential that the entire arrangement of the report be such as will show all details in the sequence of their importance with respect to the investment and returns. By showing cost and earnings on the first page and a duty cycle curve of a proposed shaft hoist with the root mean square horsepower calculations on the last page, an ideal arrangement is obtained. The average director of a coal-mining property is vitally interested in cost and earnings, but has no more interest in the root mean square horsepower than he has in the behavior of electrons in an atom of helium.

It also is important that all bookkeeping and engineering details be incorporated in the report so that the results indicated may be completely checked and the possibility of errors eliminated within the limits of certain data which must necessarily be assumed. The report also will be used as a check on the cost of various details as the work progresses. Such a report

FIG. 1—WHAT THE REPORT SHOULD CONTAIN

THE KILOWATT COAL MINING CO.

Summary

Total cost of proposed equipment erected and ready to operate.....	\$195,452.00
Net saving per year effected by change.....	148,256.25
Deduct for interest, taxes, depreciation and insurance.....	\$29,317.80
Deduct for added labor.....	7,400.00
	36,717.80
Net saving per year.....	\$111,538.45
Net saving per ton produced.....	0.147
Net saving during life of property.....	\$1,115,384.50

Note:

The output is taken at the rate of 750,250 tons per year as produced during 1922, which implies an active life of ten years for the property. The savings indicated will vary as the yearly output varies from that of 1922.

No salvage value is taken into account for the equipment replaced nor for the new equipment at the end of the amortization period of ten years.

FIG. 2—FINANCIAL STATEMENT OF PROPOSED PROJECT

is extremely valuable to any concern contemplating changes involving considerable expenditures of money, as it supplies a tangible starting point, removing many of the uncertain elements and indicating whether or not such expenditures are fully warranted.

Mortality Among British Coal Miners In Relation to Output

During the ten-year period 1913-1922, at the mines in Great Britain operating under the Coal Mines Act, the average annual death roll was 1,243, representing a death rate per thousand persons employed of 1.15, the average number of deaths per million tons of mineral raised being 4.92. During this period the annual average number of persons employed was 1,091,391, and of mineral raised 251,454,646 tons, the figure for coal being 241,081,755 tons, or 220 tons per employee.

Last year, as appears from tables prepared by the Chief Inspector of Mines, the mineral production was 255,971,696 tons, coal being responsible for rather more than 249,500,000 tons, and the persons employed numbered 1,162,754, while the deaths from accidents totalled 1,105, representing a death rate of 0.95 per thousand persons employed, the deaths per million tons of mineral raised working out to 4.32. The record for 1922 may therefore be said to be favorable when it is compared with the average for the last ten years. As the Secretary for Mines expressed it, "the picture is not one of unrelieved gloom." The tonnage per person was fully maintained.

THE COAL MINES in the Twentymile district of Colorado, according to a report by the U. S. Geological Survey, have been developed since the Denver & Salt Lake (Moffat) R.R. was extended into this district, in 1906. The coal has become widely and favorably known as an excellent fuel for both manufacturing and domestic use, but the development of mines has been greatly hampered by inadequacy of transportation facilities and by the fact that all the coal reaching the market had to be hauled up steep grades over one of the highest passes in the Rocky Mountains.

The Miner's Torch

The Children at Our Mining Camps

I HAVE just finished reading an article written by a woman who has visited a number of coal-mining camps to see what our mining companies are doing for the miners' children. It is a terrible picture that she paints and we are almost led to believe that if the men and women of the next generation have to spring from these mining-camp children, all of our schools and churches will be useless within two generations.

With the description which she gives of the things that she saw we cannot quarrel, for anyone who has lived much in mining towns in different sections of the country must agree that her sketches are true to life; but there be men living today of middle age and beyond who were raised in mining camps where conditions were worse than any to be found in mining camps of today, and these men are good citizens and some of them have even attained to positions of trust and eminence.

Things are not always as they seem. I recall an incident that happened about twenty-five years ago. I was acting as guide to a director of the company for which I worked, showing him around one of the mining camps. "Is this camp typical of all our camps?" he asked me, and when I replied in the affirmative he assured me that he was ashamed of his connection with the company. "Why," he said, "you must be breeding a race of anarchists here. Such smoke, such odors, and My God! such pitiful looking children." That camp has long since been abandoned, but I occasionally meet some of the children now grown to manhood and they are not anarchists.

Miners move around a good deal and they are out of employment quite often and they are not over-particular about the dress and the manners of their children; furthermore, the tippie often sends forth clouds of dust. Any visitor to a mining camp will discover these things and be impressed by them. But there are other things that ought to be taken into consideration before suggesting that our mine owners be hanged and quartered.

Mining villages have to be built where there is coal to be mined, which means that they are often miles from the main line of a railroad, sometimes located in gulches and at other times half way up a mountainside. Children on ranches and in logging camps or even on our farms often have a harder time in every way than the children of our miners. And if you want to find children who have fewer advantages than those of our miners, go to some of the villages around our large cotton mills.

In the same mail that brought me the article which I have discussed above, I received an article dealing with "welfare work"—so called—and its author was of the opinion that the matter had been overdone by most of the larger companies and in future many companies would expect their employees to initiate movements having to do with education, gardening, social service, etc. This author argued that the workers are beginning to resent the attitude of the employers, and that with reason.

So there you are—you can take your choice.

Belt Conveyors Well Suited For Hoisting Coal From Shallow Mines

In Most Cases Any Coal Under Less Than 225 Ft. of Cover
Can Be Hoisted by This Means — When Depth Exceeds
120 Ft., Two 500-Ft. Units Should Be Used in Tandem

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*, Pittsburgh, Pa.

SOUND advice for the mining engineer is the dictum: "Hoist coal with belt conveyors wherever the depth of the seam, the nature of the material to be excavated and retained, the daily tonnage to be handled and the life of the plant favor such a method." It must be remembered, however, that the seam should not be too deep; the material over the coal should not be too loose or water-bearing and the daily and total tonnage must justify the greater expense involved in the construction of a slope.

"Slope-conveyor hoisting" is a comparatively new term in the vocabulary of the coal industry. By overlooking the possibility of the slope conveyor when planning for the landing on the tipple of coal from beds that do not outcrop, engineers have passed by many opportunities which would have lowered the costs of underground transportation. The usual hoisting methods tie the mine management hand and foot, for, with them, only with difficulty can the output of the mine be increased.

The congestion of traffic at the mine opening delays the return of trips to the working entries and adds considerably to the uncertainties of transportation. A shaft mine is much like a big bottle with a small neck. From it the coal emerges in a broken and uncertain stream. Dispose of the coal as quickly as it arrives at the bottom landing, and the traffic will move freely. An all-around saving can be made if a belt conveyor

and a slope are provided, with the former delivering the coal direct to the shaker screens on the tipple.

In other industries moving belts have been put to extensive and varied use for carrying raw and finished materials. Many are used in anthracite breakers; they are indispensable in byproduct-coke plants, in chemical plants and in the rockhouses and concentrating mills of the ore regions. Belts of many sizes are performing efficiently elsewhere and serving better than expected the purposes for which they are installed.

In the immediate future the bituminous-coal industry will find more numerous applications of belt conveyors than at any time hitherto. Mine mechanical engineers acknowledge the usefulness of such conveyors in and about tipples, and power-plant experts recognize their efficiency in transporting coal from storage piles to bunkers. On the strength of close observation of level and inclined-belt conveyors in carrying coal, iron ores and even more abrasive rocks, mining engineers now see opportunities to simplify the operation of hoisting coal to tipples from comparatively shallow buried seams.

Uses of belt conveyors in the Lynch tipple and dump-houses of the United States Coal & Coke Co., in Kentucky, should assure us of their practicability. The permanent tipple, which has the semblance of an anthracite breaker, was completed in the early part of 1921.

Conveyor units leading from two dump-houses to the tipple have handled to date more than 4,000,000 tons of run-of-mine coal. Superimposed belts in the same galleries have carried a due proportion of mine refuse. One coal conveyor is 387 ft. long and another 404 ft. Both are 48 in. wide and travel on a slope of approxi-

Paper delivered, Dec. 4, at Huntington, W. Va., before the West Virginia Coal Mining Institute.

Headpiece shows tipple and slope of the Aluminum mine of the United States Aluminum Co. The upper Freeport seam lies only 60 ft. below the railroad tracks.

mately 18 deg. at a reduced speed of 156 ft. per minute. Traveling at maximum speed their capacity will be 1,000 tons of coal per hour each.

The two slate belts just mentioned also are 48 in. wide, move at a speed of 300 ft. per minute and have a capacity of 200 tons per hour each. These discharge at a junction tower onto the main 48-in. slate belt, which has a speed of 475 ft. per minute. The latter is 686 ft. long on a slope of 18 deg. and leads to a slate dump on the mountainside. All these belts and numerous shorter ones used for many purposes are driven by slip-ring induction motors aggregating only 720 hp.

The Lynch belt installation is proving to be highly dependable, as judged by results obtained. One can conceive of no other methods to accomplish more satisfactorily the duties of the units at this plant. True, the belts require regular attention, but any other kind of equipment for the same purpose likewise has to be carefully maintained. The job at Lynch points the way to possible installations involving the hoisting on slope conveyors of large and small tonnages of coal from buried seams.

Imagine the 686-ft. slate conveyor transposed from its present position in daylight into a slope tapping a coal seam which lies 135 ft. below the surface. The change would allow 75 ft. for tippable height and dumping facilities at the bottom of the slope. And it would afford a means of hoisting over one belt as much as 830 tons of coal per hour when traveling at the rate of 450 ft. per minute.*

Traveling at the speed specified, the belt would carry a load of about 20 tons of coal. Possibly the splices would not carry so great a load. In that case the rate of feed could be reduced to distribute a load of 14.5 tons of coal over the length of the conveyor. That is the load recommended by belt experts for 48-in. belting traveling at a speed of 450 ft. per minute on a 500-ft. conveyor unit.

The main coal conveyors at Lynch, with exactly the same characteristics, are calculated to carry a load of

14.3 tons. Carrying a load of 14.5 tons, the belt would transport coal at the rate of 675 tons per hour. Thus is a 5,400-ton hoisting layout in the making.

A slip-ring induction motor no larger than 100 hp. would be sufficient to drive the conveyor. The main slate conveyor at Lynch is driven by a 100-hp. motor. At the Kinloch mine of the Valley Camp Coal Co., in Pennsylvania, a 150-hp. motor drives an apron conveyor weighing 40 tons, which carries a load of 40 tons of coal, is 430 ft. long and on a 30-deg. slope.

Consequently one is conservative in assuming that a 100-hp. motor would be of ample size to drive the 686-ft. conveyor carrying a load of 14.5 tons of coal. Undoubtedly, belt conveyors in slopes will show a saving in power when compared with cages or skips under like conditions.

Much in the choice of hoisting by slope conveyors in preference to cages or skips depends upon these four closely related factors: The nature of the overburden in which a slope must be sunk, the depth of the seam, the first cost and the production desired.

Where the cover is as much as 200 ft. thick and composed chiefly of loose ground or strata of rock which bear an abundance of water, the sinking and lining of a slope would be impossible or otherwise very costly. In the last event only a large production would justify the expense. In solid cover a slope may be sunk and lined without serious difficulty but here again the desired output must influence the choice.

In general the depth from which coal should be hoisted by belts is governed by the output desired. By placing two 500-ft. conveyor units in tandem, a rise of more than 300 ft. can be obtained. Coal from seams lying at depths of 225 ft. can be hoisted by means of such an arrangement at the same theoretical rate—5,400 tons in eight hours—as that of the single-unit conveyor mentioned earlier in the paper.

That is precisely what the Hudson Coal Co., of West Virginia, proposes to do at its Indian Creek operation, near Morgantown, W. Va., where the Sewickley seam is to be mined at a depth of about 275 ft. The total rise of the two conveyor units in tandem being about 350 ft., each unit will have to be about 550 ft. long, if the slope is 18 deg. This mine is being planned to produce 4,000 tons of coal per day.

The trend of present-day opinion is that the depth from which coal may be economically hoisted by means of slope conveyors ordinarily will not exceed 225 ft. That depth will require two 500-ft. conveyor units in tandem on an 18-deg. slope, as already stated. It is possible, nevertheless, to hoist economically from slightly greater depths by means of longer conveyor units, as pointed out in the case of the proposed Indian Creek operation of the Hudson Coal Co. Who knows? In the future we may find it economical to hoist from depths of 300 ft., using three conveyor units in tandem or 400 ft. with four such units. Only a very large production, however, could warrant these extremes.

On the depth of the coal seam below the surface hinges the application of slope conveyors for hoisting small daily tonnages. Wherever slope-sinking operations are easy, the cover is less than 100 ft. thick, and the mine is to produce 2,000 tons of coal per day, hoisting by belt might be preferable to cage hoisting. Most 1,000-ton mines in coal 50 ft. below the surface are best served by belt conveyors.

The total first cost of sinking a slope and installing a conveyor may be more or less than that of shaft and

CONVEYOR IN TILE-LINED SLOPE IN LEWIS MINE

Where, as in this case, the length of the conveyor is less than 250 ft. and the tonnage of coal carried by it is not more than 2,500 tons per shift, the base of the conveyor can be built of wood at low cost. This arched slope is lined with tile, the cost of this type of construction being two-thirds that of concrete.

*Based on table in Marks' Mechanical Engineers' Handbook.

A 430-Ft. Pan Conveyor

At the Kinloch slope. Because so long it must necessarily be made of heavy material. This conveyor weighs 40 tons and carries an equal weight of coal. It is driven by a 150-hp. motor, but one of 100-hp. would carry the average load. When this conveyor was installed mining men shook their heads. It has proved after five years of service one of the most efficient devices in the industry.

cages. The cost per foot is greater for sinking a shaft than for a slope. But when sunk at 18 deg. a slope is nearly three times as long as a shaft of the same depth. For this reason the cost is more for a completed slope than for a shaft at the same location. That factor is fixed. On the other hand, slope equipment will in most cases cost less than shaft equipment.

Hoisting by means of self-dumping cages would be a better arrangement if only 2,000 tons of coal per day were required from a seam lying at a depth of, say, 200 ft. The first cost would be less than that of an arrangement involving a slope conveyor. Primarily, the greatest merit of a slope conveyor is its continuous performance, which makes for a continuous dumping schedule on the slope bottom. It is best suited to a mine having a large production.

It is readily apparent why large tonnages may be handled with greater efficiency by a belt conveyor than by cages or skips. As rapidly as coal is dumped into bins it is fed onto the conveyor. Properly functioning skips do not retard the rate of dumping, but they are much more likely to get out of order. The added cost of skips and their more complicated bottom layout favor the use of belt conveyors.

The slope conveyors now in actual use are giving excellent service. The installation at the Kinloch mine of the Valley Camp Coal Co., at Parnassus, Pa., is outstanding because this mine ranks on merits of production as one of the "Big Three" in the Pittsburgh district. Its actual daily output is 3,400 tons. Though a pan conveyor is used, the arrangement has many features common to belt conveyors. Its reliability is indicative of what one can expect when belts are used.

At the Kinloch mine a 30-deg. slope having a length of 430 ft. strikes the Thick Freeport seam at a depth of 150 ft. below the slope mouth. It is wide enough to accommodate a 60-in. pan conveyor, a mine track for materials and slate and a stairway for man travel. The conveyor is fabricated heavily, as it must be, weighing 40 tons and carrying a load of coal equal to its own weight. Even so, a 150-hp. motor is sufficiently large to move the conveyor and coal at the rate of 75 ft. per minute. The capacity of the unit is 475 tons per hour. A double track extends 500 ft. from the tail of the conveyor. The arrangement for handling trips is like that generally used on the surface at a drift mine, a kickback and two car hauls serving their customary

purposes. Six men are employed on the bottom for the usual duties of uncoupling and coupling mine cars, dropping them to the dump, spotting, taking checks and dumping. A crossover dump empties the mine cars into a 9-ton chute pocket, from which the coal is fed to the main conveyor by means of an apron feeder.

The most notable feature of the dumping and hoisting arrangement at this mine is its operating continuity, for three 2½-ton mine cars are dumped in a little less than a minute. For this reason only 600 mine cars are required for the haulage of 3,400 tons of coal, though the mine is well developed.

Slope hoisting, therefore, like skip hoisting, has the advantage over hoisting by means of cages in that mine cars are dumped at the foot of the slope and are immediately available for use, which means, or should mean, that fewer mine cars are required for a given output. Consequently there should be less congestion on the bottom.

Only once in a period of five years has a long delay in transportation been caused at Kinloch by the breaking down of the pan conveyor. In that specific case the delay lasted several hours. Belt conveyors should do as well, and probably will, providing they are watched carefully and defects repaired immediately in off-shifts.

A typical application of belt conveyors for hoisting from shallow depths is made at the Lewis mine of the Hudson Coal Co., near Clarksburg, W. Va. The conveyor from tail to head rises 83 ft. in a distance of 247 ft., forming a slope of 18 deg. A 75-hp. motor is reduced by gears to move the belt at the rate of 250 ft. per minute. At that speed the capacity of the conveyor is 250 tons per hour. The same motor will drive the belt at a maximum allowable speed of 500 ft. per minute to carry 500 tons per hour.

An example of an extreme application of slope conveyors for hoisting coal is the installation at the Aluminum mine of the United States Aluminum Co., near Pittsburgh, Pa. The site of the mine plant is on the bank of the Allegheny River. An intervening railroad prohibits the bringing of mine cars to the river tippie from the Upper Freeport seam, which outcrops at about the level of the railroad track. The problem was solved by erecting a conveyor gallery at tippie height across the railroad tracks to connect with a gently inclined slope which penetrates the hill. The belt is 30 in. wide and 180 ft. long, driven by a 25-hp. motor at a speed

of 270 ft. per minute. The capacity of the conveyor is 195 tons of coal per hour.

No better arrangements could be made for bringing coal to the surface at the Lewis and Aluminum mines. Hoisting coal up shafts from depths of 50 ft. is not practicable. Rope or chain haulage in a shallow slope is no longer recommended where the output is sufficiently large to justify the use of a belt conveyor. The arrangement at the Aluminum mine is ingenious and suggests another use of belt conveyors, namely, for solving peculiar problems of plant layout.

A mistake was made not long ago at a mine in Pennsylvania. Because a chain haul in a slope 250 ft. long and 60 ft. deep was inadequate to handle increased production during the war period, the management of the mine abandoned the use of the slope for haulage purposes after first sinking a shaft and erecting a new tippie. The bottom could have been altered to meet the requirements of a slope conveyor without seriously interfering with the daily operation of the mine.

In that event mine operation could have been suspended for a week or two while a temporary slope conveyor was being installed and a few alterations made on the tippie. The shaft and equipment today are as inefficient as the chain haul they displaced was inadequate. This mine is now producing nearly 3,000 tons of coal a day. Attempts to maintain a high rate of hoisting by quick acceleration and retardation in a short lift are shaking the headframe and the tippie and causing much spillage of coal during dumping.

No mining man need hesitate in accepting the possibilities of belt conveyors for transporting coal horizontally or on inclines because of doubts as to the life and dependability of composition belting. Reliability is a quality of well-designed belt conveyors. Only rarely is a duplicate unit installed as a precaution against breakdown. Standby units are not even provided in byproduct-coke plants which operate 24 hours per day, year after year. Belts with good splices seldom break without giving warning months in advance, whereas hoisting ropes sometimes snap in two without warning and apparently without an indication of weakness. Splices are not likely to break inopportunely unless a belt is greatly overloaded. At the Lynch plant the life of a splice is about two years.

Like the life of an automobile tire the life of a belt depends largely on the care taken of it. Its life will be greatest when it runs continuously with a capacity load. Weakness in a belt is not entirely the result of wear. In time it weakens from the effect of changing climatic conditions, moisture and strains caused by tension and bending. The greater the tonnage passed

over a belt in a given period of time, the longer will be its life, figured in tons. Consequently the maximum productive life will be obtained at mines of large output.

From many sources come accounts of long life of belts under all kinds of conditions. If composition belting were not dependable and extremely serviceable, other industries would not use it as they do now in places where continuity of service is a requisite. In the coal industry such records of belt longevity are on file as should allay the doubts of the most skeptical.

A 36-in. belt should have a life of not less than 2,000,000 tons of coal when properly installed and maintained. At the No. 9 mine of the United States Coal & Coke Co. at Gary, W. Va., a 36-in. belt on a 235-ft. conveyor, moving at a speed of 480 ft. per minute, carried 3,300,000 tons of run-of-mine coal in a period of eleven years. If intermittent operation and severe service curtail its life to one-half the figure given above, the life of a belt would still be considered long.

One 36-in. belt is credited with having carried 12,000,000 tons of pulverized coal, but that was a freak performance. In the Marvin colliery of the Hudson Coal Co. of Pennsylvania, two 36-in. belts in tandem units have been in service more than two years. During that time they have carried more than a million tons of anthracite under 4½ in. Yet they show no appreciable signs of wear. The well-preserved appearance of some of the belts in the tippie at Lynch, after carrying more than 2,000,000 tons of mine-run coal, is sufficient basis to forecast a life of twice that tonnage. Most of the sections of the main slate belt at this plant have been subjected to harsh abuse by over 500,000 tons of slate and continue to give service. Certainly the cases cited are sufficient proof that belt charges are low when figured on a per-ton basis.

The sizes of belts recommended for the transportation of the whole mine output vary from 30 to 48 in. Belts of these sizes, running within the maximum limit of speed, will furnish capacities up to 1,000 tons of coal per hour. If a still larger capacity is desired, a 54-in. belt can be used.

Most belt-conveyor experts recommend that for ordinary purposes conveyor units be no longer than 500 ft. and that the slope be no more than 18 deg. By increasing the belt speed or decreasing the feed, a belt conveyor may be lengthened to as much as 700 ft. on such a slope. It is a safer policy, whenever an inclined belt must be longer than 500 ft., to make it as near that length as possible even though horizontal belts may be used of much greater length.

Belt conveyors will carry coal on a slope of 20 deg. or slightly more but when they are being operated to

Dump at Kinloch Slope

In the Kinloch mine the mine cars are dumped into a bin, a pan feeder taking the coal to a belt conveyor. A spring latch and a kick-back switches the empty cars to the empty track. Cagers and cagers' helpers are eliminated.

CONVEYOR HANDLES 2,000 TONS PER SHIFT

Only five men and the conveyor are required to transport the output of the mine from the wagons to the screens on the tippie.

capacity the coal at the point where the conveyor is being emptied of its load may roll back, with unfortunate results. When the slope is thus steep one is never safe in the vicinity of the belt conveyor. Judgment suggests a limit of 18 deg. except for short distances, as at the overlap with tandem units.

The application of belt conveyors for hoisting in slopes, especially those of great length, presents several problems. The most important one perhaps is how to arrange the slope to accommodate a conveyor, manway and supply track. The Kinloch slope has only one wide compartment, in which the three travelways are located side by side. This practice is not advisable from the standpoint of safety.

The slope of the proposed Indian Creek operation of the Hudson Coal Co. of West Virginia is double-decked. At the spring line of the arched slope, which is about 14 ft. high and 11 ft. wide, a concrete floor reinforced with 6-in. steel beams will form the setting for the belt conveyor in the upper compartment. In the lower compartment will be placed the supply track, leaving ample room for a manway.

ESCALATORS MAY BE INSTALLED FOR MINERS

In sinking a slope for a belt conveyor 1,000 ft. long or longer on an incline of 18 deg. the mine owner faces another problem: Will it be fair to expect a miner to climb a long stairway after a hard day's work? This objection might be met by installing one, or perhaps two escalators. The device is in successful use for transporting men to an elevated seam at a mine at Ward, W. Va.

Not all are agreed as to how the lower of two conveyors in tandem should be arranged to discharge coal onto the upper. I have in mind one proposed plan which specifies that the floor line of the lower half-length of the slope be above, but still parallel to, the floor line of the upper half-length. This arrangement would facilitate lapping the lower conveyor unit over the upper. The roof, of course, would have to be made higher above the junction, where also a hump would occur in the floor. This layout is not advisable as it would add to the difficulties of sinking and the offset would obstruct a free downcast of air.

A more logical layout is proposed in which a common floor line is provided for both conveyor units, with the roof made higher at the junction. To raise the head end of the lower conveyor unit sufficiently to give an

overlapping at the junction point, the head end of the lower conveyor is sprung at an angle greater than the primary slope. Chute plates will most likely be used to ease the fall of coal at a junction.

Roller bearings on idlers are advantageous not so much because they reduce power consumption but rather because they greatly reduce attendance for lubrication. Plain bearings bind at times in spite of proper care. Grease cups on them must be filled every other day on an average; the more often they are turned during the course of a day the better.

Grease cups on roller bearings need be filled only once in two months and given a half turn each day. At Lynch they are filled once a month and given a whole turn each day to insure the injection of sufficient lubricant to the bearings. The Alemite system of pressure feeding, as used on automobiles, has been suggested. With it as many as twenty idlers are lubricated through pipe connections. The scheme is not believed to be practicable now but may be worked out later.

Conveyors for hoisting coal are disadvantageous in that a means for inspecting coal after it has left the mine car cannot well be arranged. Nowadays every effort is made to detect miners who load dirty coal and give it a good appearance by topping the car with clean coal. Market competition demands close surveillance of the contents of all mine cars. The possibility of providing an arrangement for facilitating the inspection of coal is a subject requiring consideration.

SLATE MUST TRAVEL BY ANOTHER ROUTE

Contemplated slope-conveyor layouts call for the hauling of slate up the slope in mine cars by a rope. This provision seems crude when coupled with the highly efficient conveyor systems for hoisting coal. At least in large mines which take much slate to the surface, a belt conveyor could be superimposed upon or placed at the side of, one carrying coal. This might be used for taking slate to the tippie from which point it might be transported to the slate dump by another conveyor unit. Here is an opportunity to save much labor, and here again the arrangement at Lynch should serve as an inspiration. As already stated, secondary conveyors from the dumphouses discharge slate onto a main conveyor 686 ft. long and on an 18-deg. slope, ending at the slate dump on the mountainside. Some sections of these belts are expected to carry as much as 1,000,000 tons of slate before they are replaced.

By reason of its operating continuity a belt conveyor will maintain a steady, uniform stream of coal over the shaker screens, unlike the spasmodic discharge of two to ten tons of coal in mass. Consequently, the efficiency of the screens and of the attendants on the picking tables will be increased. Regularity of feed also will markedly lessen the vibration of the tippie.

By the adoption of the belt conveyor for hoisting coal, labor will be saved. Specialized attendance is not needed to control belt conveyors. The men who look after moving parts on the tippie can start and stop them at will by push-button controls. Thus the service of hoist operatives is dispensed with. Aside from lubricating, no other attention need be given to belt conveyors while they are in motion. Like the skip, they will eliminate the need for cagers and cagers' helpers and an attendant on the dumping platform of the head-frame. Only as many men should be needed on the slope bottom as are necessary at the dumphouse of a drift mine.

How 1921 Agreement Has Worked Out In British Coal Mines

Miners Renew Demand for Revision
— Seek Amendment Rather Than
Destruction — Receive 83 per Cent
of Profits, Want 87 per Cent

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

SINCE my return from the British Isles, renewed demands have been made for a revision of the British coal agreement of 1921. At this writing the matter still is under discussion, but despite wide dissatisfaction with some of the terms of the agreement, the predominant demand, as stated previously in this series, is for amendment rather than the destruction of the agreement.

The mine workers now are asking for an increase in the minimum wage. The minimum fixed by the agreement was 20 per cent above the basic wage of each grade of labor in July, 1914. The mine workers ask that this be increased to 40 per cent. They ask further that they be allowed 87 per cent of the standard profits instead of 83 per cent. There are additional demands dealing with the publication of further particulars of costs of production.

So that the existing controversy may be better understood, a condensed summary of the original profit-sharing agreement may be of interest. The agreement provides for the substitution of all the pre-war standards by a new standard wage, representing in each coal field a basic wage equal to the aggregate earnings of each grade of labor in July, 1914. A standard rate of profit is fixed for the capital used in the industry, and the surplus proceeds, after meeting the minimum wages and deducting other allowable costs of production, are divided in the fixed proportion of 83 per cent to labor and 17 per cent to capital.

The mine workers have contended from the start that they should participate in any profits derived from the industry as a whole. It was determined finally, however, that they should not share in the profits of the following related activities: Coke ovens and byproduct plants; smokeless fuel plants; manufacture of patent fuels; selling agencies and merchanting depots; operation of ships, barges and private railroad cars; privately owned railroads; farms and cottages; washeries and electric-power plants, except those at the mine.

OWNERS' DEFICITS NOT RECOVERABLE LATER

The standard wage is the first charge against the industry. In those cases where the proceeds have been sufficient to meet the standard wages, other costs and the standard profits, but insufficient to pay the mine workers the minimum wage, the operators have had to surrender the whole of their standard profits and are not allowed to carry forward against future income any such deficiency in their standard profits. This swallowing up of the operator's standard profit and any claim he may have for recoupment have resulted in determined protest. The operators contend that the agreement should be altered so that they may receive the same proportion of their pre-war profits as the miners receive of their pre-war wages and that temporary

deficits should be recoverable when conditions improve.

Under costs of production admissible under the agreement come such items as timber, supplies, depreciation, royalties, surface damage and restoration, workmen's compensation payments and insurance, health and unemployment insurance, remuneration of mine foremen, rescue work, aid service, fire service, welfare fund. Among the operator's costs which have been held to be inadmissible are interest on capital and loans, contributions to trade associations, income tax and corporation profits tax, amortization of capital.

It is generally admitted that one of the great needs of the present agreement is to rearrange the districts. The mine operators originally contended for twenty-six districts. The mine workers wanted only one district. This resulted in a compromise that set up thirteen districts. It is believed that the mines can be gerrymandered into better groups. A joint committee of miners and operators now is engaged in a study of points in disagreement. The miners in South Wales, Lancashire, Durham and Scotland are particularly insistent on their demands for a larger share of standard profits. Frank Hodges, secretary of the Miners' Federation, has been a consistent supporter of the agreement, but he now is faced with the possibility of independent action on the part of the mine workers in the district mentioned above. Independent action would disrupt the federation and it is possible that a general vote will have been taken by the federation before this article appears in print. The coal agreement is terminable on three months' notice by either mine workers or operators.

WAGES ADVANCE 35 PER CENT

Mr. Hodges told George S. Rice, chief mining engineer of the U. S. Bureau of Mines, in September that the average increase in wages, as compared with 1914, had been only 35 per cent, whereas the increase in living costs was 70 per cent. On the other hand, he contended that the operators are getting a disproportionate amount of the profit. Since the 17 per cent is based on an average it results in many mines, Mr. Hodges said, making more money than ever before has been the case. He admitted, however, that many of the operators are in a bad way. He contended that the operators would be better off under a pooling arrangement covering the entire United Kingdom. He admitted that the banks will have to be particularly liberal in the case of some mines.

The high-cost mines must pay the standard wages even if they lose money. Mr. Hodges pointed out to Mr. Rice, however, that improved management in certain of these properties would make their situation less acute. In that connection it may be pointed out that deficiencies in management cannot be covered up, as was the

case under the old sliding scale, when there were periodic revisions of general wage rates according to fluctuations in prices and in volume of trade.

An idea of how the distribution of the proceeds works out may be had from the results of the joint audit of the South Wales field for May and June, which happened to be issued during the time that I was in the United Kingdom. That audit gave an advance of 3.85 per cent on the standard wage which was payable during September and October. The available surplus, which is divided 83 per cent to labor and 17 per cent to capital, was £1,606,118, or £215,639 more than in March and April. For Great Britain as a whole, during the time that I was in England, production was running slightly over 5,000,000 tons per week. The highest weekly output during the twelve which had preceded was that during the week ended April 21, when 5,824,900 tons had been produced.

Due to the basic importance of coal to British trade, both operators and mine workers are much interested in keeping the output at the highest possible point and are interested in winning all of the coal. Much study has been given the subject of eliminating the waste represented by unmined coal.

Next week Mr. Wooton will give further details of the working of the 1921 agreement.

Standardization of Underground Power Transmission

Factors Influencing Transmission Efficiency—Variation of Efficiency Due to Variable Loads
With Low Load Factors

BY CARL LEE
Peabody Coal Co., Chicago, Ill.

THE objects of standardization in mining have been nicely stated in the three words, safety, efficiency and conservation. The objects of standardization in underground power transmission might be correctly summed up in the words, safety, efficiency and economy.

The first of these, safety, is covered by a long list of rules developed principally from Bureau of Mines Technical Paper 138, "Suggested Safety Rules for Installing and Using Electrical Equipment in Bituminous-Coal Mines," and rules of the National Electric Code.

The second object, efficiency, as applied to machinery is very well covered by the standardization rules of the American Institute of Electrical Engineers. Well-defined rules for testing, well-known laws of design, and keen competition in manufacture assure the mining industry of efficient electrical equipment.

Efficiency, as applied to underground power transmission may be simply defined as the ratio of the voltage at the load end of the line to the voltage at the generator end of the line. For any given steady load this may be measured by means of meters. For a simple two-wire circuit it may be quite closely calculated from tables or charts.

It is not physically possible to have 100 per cent efficiency in transmission. The usual 2 to 5 per cent loss in lighting circuits is almost impossible for mine circuits and even the 10 to 12 per cent loss sometimes found in industrial plants usually is unattainable for the average mine.

In many states the maximum trolley voltage allowed by law is 275. Mine generators usually are designed for 250 volts at no load and 275 volts at full load, thus compounding 10 per cent. This compounding partly offsets the drop in voltage or loss on the line. The loss frequently, if not in the majority of cases, is over 20 per cent. Thus 275 volts less 20 per cent equals 220 volts at the load end. Manufacturers have realized the average conditions existing and therefore generally use 210- or 220-volt motors on coal-mining equipment.

The efficiency of transmission depends principally on the following: Voltage used, size of load, size of conductors, length of conductors, joints in negative and joints in positive.

For any given circuit an increase in the load decreases the efficiency of transmission almost inversely. For a given load and voltage an increase in the size of the conductors will increase the efficiency almost in direct proportion, while an increase in length will decrease it almost inversely. The joints in the conductors affect the efficiency in a similar way as the length affects it. The poorer the joints the lower the efficiency. This often plays an important part where the rails are used as the return circuit.

Ideal conditions where the load is steady and concentrated, the joints perfect, and the wires the same size on both sides of the line are seldom found. Such cases can be calculated, the proper efficiency decided upon and the exact wires required to give that efficiency installed. Unfortunately, these are rare cases in mining service.

The actual conditions usually met are complicated and require considerable calculation to arrive at even an approximate figure to represent the efficiency of transmission. Even with those figures at hand there is another factor to be considered. That is the economy of the entire mining operation. It is here that further study and standardization from an engineering standpoint will mean a great deal to the industry.

The efficiency of transmission required from an economic standpoint will depend upon or be affected by: (1) Cost of power at the main generating station or substation; (2) cost of copper and upkeep of lines; (3) load factor.

The efficiency of transmission should be increased as the cost of power increases. Thus the reduced losses would partly offset the increased cost per kilowatt-hour.

The cost of copper is reflected principally in an interest and depreciation charge, which is a considerable item, but not nearly so great as the cost of power.

The load factor affects the economy of transmission. If a line has a high load factor the percentage losses should be kept low; on a low-load factor the losses may be high for peak loads and low for light loads.

The load factor will be affected by the character of equipment used, thus: (1) Haulage locomotives usually have a low load factor; (2) gathering locomotives usually have a slightly higher load factor than haulage locomotives; (3) mining machines having shunt-wound motors and working at the face usually have a somewhat higher load factor than either of the above; (4) pump motors and fans generally furnish a higher load factor than any other form of load.

The various points mentioned are those that appear important in the consideration of additional standardization rules. A great deal of study will be required to formulate general rules to cover the subject of power transmission.

Storage: The Power to Make or Break Coal Market

Relation Between Consumers' Stocks and Price Almost Mathematical
—Reserve Below 30,000,000 Tons a Sellers' Market—20,000,000
Tons the Panicky Point—Above 40,000,000 Tons Favors Buyer

BY F. G. TRYON AND W. F. MCKENNEY

STORAGE is not an untried thing, an experiment to be urged upon a public entirely unfamiliar with the idea. With a great many coal consumers it is instead an established practice of years' standing. Like superpower, while we are talking about it, it has come. The pioneering in coal storage has largely been done, and the task of promoting now lies chiefly in inducing consumers who already store coal to store a little more, or inducing consumers who live from hand to mouth to adopt a practice that others in their own territory have long been following. The economic advantage of storage under some conditions became apparent long ago, and increasing economic pressure is rapidly extending the practice today. The problem of the engineer is therefore not merely to guard against spontaneous combustion, not merely to devise means to cut the cost of handling and reclaiming, but chiefly to show that it pays to store. If the economic incentive can be supplied, storage by consumers will come fast enough. The following is an abstract of a paper read at the annual meeting of the American Society of Mechanical Engineers.

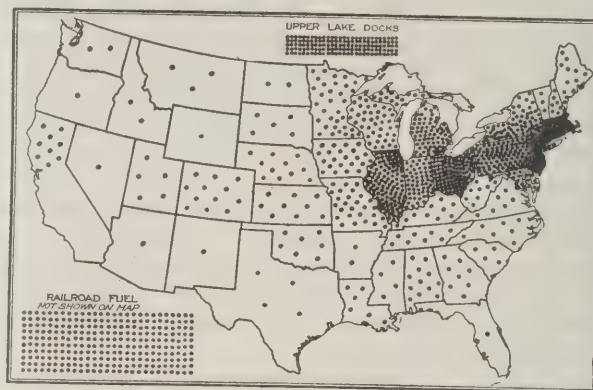

FIG. 2—WHERE COAL IS STORED

The geographical location of reserve stocks is influenced not merely by the number of consumers in a locality, and the amount they consume but by the fact that stocks increase as distance from the mines increases. The region of greatest density of storage is southern New England. In the three states of Massachusetts, Connecticut and Rhode Island there were approximately 6,000,000 tons in storage on Armistice Day. Other areas of dense storage are northern New Jersey, New York, Ohio, Pennsylvania, the Detroit district and the Chicago district.

TO APPRECIATE how far the practice of storing even bituminous coal has progressed, one need only consult the government's latest report on consumers' stocks of coal. On Sept. 1 commercial consumers and retail coal dealers had on hand an estimated total of 56,000,000 tons of soft coal, which is equivalent to five weeks' output at the present rate of production. This figure does not include 6,400,000 tons on the Upper Lake docks, 440,000 tons stored by the producers at the mines and at intermediate points, the millions of tons in transit in railroad cars and in vessels, and the large tonnage in the cellars of householders. This 56,000,000 tons is simply what commercial buyers of carload lots had on hand at points of consumption. The reports of these consumers furnish an adequate basis for estimate because the relation of their stocks in

FIG. 1—WHO STORES THE COAL

The largest reserves of coal above ground are held by the general industrial consumers. The general industrials, other than coke ovens and steel works, had 44.1 per cent of the total in consumers' storage on Armistice Day (November 11, 1918), and 32.8 per cent on September 1, 1923. The next largest tonnage is that held by the railroads, which are followed in order by retail coal yards, electric utilities, by-product coke ovens, steel works and coal-gas plants.

1918 to the total stocks at that time found by actual count by the Fuel Administration is known.

The records of consumers' stocks include all coal on hand at the consumers' plants, whether in specially designed storage yards or in bunkers or bins, or simply in piles on the ground. How much of the large tonnage that accumulates under certain conditions is accommodated in specially constructed yards is not known. It is a mystery where the 60,000,000 odd tons that was accumulated by consumers in anticipation of the strike of 1922 was stored. Much of it was stored in emergency stockpiles, inconveniently placed and inadequately protected. We can take it as proved, however, that, given the incentive, the consumer can find means to store.

To equalize the seasonal demand for coal and relieve the winter burden of railway traffic would require the storage during the summer of only 20,000,000 tons more than is already stored. American consumers can manage to find room for this additional 20,000,000 tons. It could be put away without involving the construction of new yards, simply by utilizing more effectively the existing storage facilities or by expanding the crude arrangement of the ordinary small plant.

An interesting fact is that the smaller plants carry greater reserves, expressed in terms of days' supply, than the larger plants. This condition, shown graphically by Fig. 5, was in part the result of a deliberate policy of the Fuel Administration to give the smaller consumers priority in accumulating heavy stocks.

Stocks of the Provident and Improvident.—Up to this point we have been talking in terms of average stocks for the country, for some district, or for some class of consumers. In every community some consumers habitually live from hand to mouth and others habitually carry a reserve even larger than that which may be warranted by the condition of the market.

FIG. 3—THE SIZE OF RETAIL DEALERS IN SOFT COAL

Out of 21,207 coal dealers covered by a study of the Fuel Administration made in 1917, only 321 did a business in bituminous coal of 25,000 tons or more a year. Yet these 321 dealers handled 38.8 per cent of the total business. They probably carried nearly as large a share of the stocks in reserve.

FIG. 4—SMALL INDUSTRIALS HAVE GOOD STOCKS

Small plants appear to carry a larger days' supply of coal in storage, but hold a relatively small proportion of the total tonnage in stock. From a study by the Fuel Administration of reports from 19,729 industrial plants (other than steel and by-product coke works) buying coal in carload lots; representing conditions in August, 1918.

FIG. 5—DAYS' SUPPLY CARRIED BY LARGE AND SMALL INDUSTRIAL PLANTS, AUGUST, 1918

Bars represent days' stock of soft coal on hand in August, 1918, would last at current rate of consumption. From study made by the U. S. Fuel Administration covering 19,729 general industrial plants, not including byproduct coke and iron and steel works.

When the distribution of the reserve in storage is very unequal a shortage in supplies quickly brings distress and consequent sharp and excessive rise in price. We know now that the acute distress of consumers in the winter of 1917-18 was intensified by a very unequal distribution of stocks. A stoppage of rail deliveries due to severe winter weather and congestion of the railroads caught many consumers with no stocks at all. The price at that time was held down by government order, but all remember the heatless days and lightless nights that marked that period. When prices are not under control it is the frantic bidding of buyers caught without supplies that has the most explosive effect upon the spot price.

Quite significant is the curve in Fig. 6 showing the stocks on June 1, 1920, when the "coal panic" of that year was approaching its height. Some champions of the coal trade have held that the shortage of that year was purely psychological, but the figures tell a different story. Seven per cent of the industrial plants reporting on June 1, 1920, had been reduced to less than two days' supply.

Changes in Price.—What is there to offset the cost of storage? Leaving out of consideration its effect in stabilizing prices, the advantages claimed for storage are: (1) Saving in price through purchasing when coal is cheap, and (2) insurance against shutdown of plant. Of these the insurance appears to make the stronger appeal. The remark is commonly heard, "There is no saving in price, but a man will pay anything to avoid shutting down." This remark is only half true, because most consumers know that even at times of shortage they can procure coal if they are willing to pay a price high enough to take it away from someone else.

The consumer has always the option of buying in open market. He is not justified in buying on contract except when he feels that in the long run he can do just as well as in the open market; and the test of the value of storage to him turns on whether or not its cost is kept within the range in the spot price.

Consumers' Stocks Control the Price.—The point to be emphasized is the powerful influence which stocks themselves have upon the price. The direct relation between spot price and the total tonnage of coal in storage is shown by Fig. 8. In this diagram the black columns represent the total quantity in the hands of commercial consumers on all dates of record from October, 1916, to September, 1923. The condition of stocks in between the black columns is not known exactly but may be inferred from the other facts of

supply and consumption. Across the diagram moves a jagged line of spot price.

Output alone does not control price. Production made new records throughout the shortage of 1916 and 1917 and in the end nearly every consumer got his coal. A drop in production does not seriously affect prices until it is registered in lower stocks. As shown in the diagram, every time stocks have fallen below 30,000,000 tons the price has immediately increased and when it has dropped close to 20,000,000 tons the market has been in a state of panic.

So direct is the relation in the rest of the curve that we might almost plot the course of what prices would have been during the life of the Fuel Administration had they not been fixed by government order. Low stocks in the autumn of 1917 meant distress of consumers and would have meant runaway prices if the price had been free to respond. On the contrary, when stocks had been built up to a high level, late in 1918, there were districts in which the operators could not have obtained even the maximum price set by the Fuel Administration. Again the panic price of 1920 was related to extraordinarily low stocks, the consequence of the miners' strike of the preceding autumn, of severe

FIG. 6—INDUSTRIAL PLANTS GROUPED BY DAYS' SUPPLY OF SOFT COAL ON HAND

This shows the range in stocks at industrial plants on three dates, which typify the varying conditions of the last five years. The heaviest stocks were on Jan. 1, 1919. Some 40,000,000 tons had been placed in consumers' storage during the war year, 1918, and the condition more nearly represented general saturation than ever before, yet even then 60 plants were carrying less than two days' reserve and 122 were carrying two days' but less than seven days' reserve.

FIG. 7

Spot Price

Data for 1913 to 1923 cover fourteen coals that represent nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared, and run-of-mine normally shipped, and second with respect to the tonnage of each normally produced. This average is published currently in *Coal Age*. Data for 1912 and earlier years have been compiled by Mr. Tryon in as nearly the same way as the records permit, and though subject to revision are fairly comparable.

weather in February, and of the switchmen's strike, which handicapped the railroads from April to June, 1920. When, by the end of 1920, stocks had been adequately built up, the price quickly dropped to normal. Large reserves were maintained throughout 1921 and the price was correspondingly low. So dull was the market at this period that non-union operators cut wages and coal from union mines was sold at the barest margin if not at a positive loss.

Again, it was not until the heavy reserves built up in anticipation of the 1922 strike had been reduced below the level of safety that the price rose wildly. The same almost perfect inverse correlation is shown by the course of stocks and the course of prices since the settlement of the strike in September, 1922.

The lesson is not far to seek. Consumers collectively have the power to make or break a market. The relation between the consumers' reserve and the price is almost mathematical. A reserve below 30,000,000 tons indicates a sellers' market; 20,000,000 tons indicate a panicky market; and above 40,000,000 tons indicates a buyers' market in which salesmen again take the road and solicit business on the consumer's terms.

How Much Should Individual Consumers Store?—The record also includes a lesson for the individual

consumer. If he is to profit to the full from the policy of storage, let him store more than his neighbors. He can then stay out of the market while his neighbor is in distress and is bidding up the price to scarcity levels.

Many consumers live off their stockpile; clearly it is a mistaken policy. For two months after the strike of 1922 broke the price rose but little, and though the walk-out of men in the non-union fields showed to a keen observer the seriousness of the situation, the mass of consumers were so apathetic that mines in the non-union fields of West Virginia and Kentucky did not have orders enough to run full time.

The time to utilize the stockpile is not in the first stages of the suspension but in the last stages, or even for months after work has been resumed. Practically all these great suspensions have ended in the same way. They have ended in distress among consumers, rapid increase in price, pressure on the union operator to settle up and take care of his customers, and still more powerful, the operators' desire to participate in the highly profitable market that follows the strike. Why be one of the consumers whose distress forces a settlement? Would it not be better business, if the consumer is to store at all, to store enough to carry him past the peak of the price?

FIG. 8
Stocks and
Prices

Black columns represent tons in hands of commercial consumers and retailers on all dates for which a canvass of stocks was made. Curve represents *Coal Age* index of spot prices f.o.b. mines, the average price July, 1913, to June, 1914, being taken as 100; adjusted, however, to eliminate increases due to the several increases in union wage rates. Thus adjusted the fluctuations in price reflect only the changing conditions of the market.

News of the Industry

Restriction of Trade Associations Seen As Foretaste of Coal Legislation

Action Against Cement and Tile Manufacturers Heartens Champions
of Compulsory Statistics—New England and Northwest
Coalesce for Anthracite Control

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

The successful way in which the Department of Justice is adding scalps to its belt in its campaign against trade associations has an important bearing on the legislative program as it pertains to coal. Judge Knox's action against the cement manufacturers, following as it does on the heels of the decree in the tile manufacturers' case, restricts further the chance of obtaining voluntary statistics from the coal industry. It is certain to give new heart to those who contend for compulsory statistics.

In this connection, the unexpected has happened in Pennsylvania, and apparently the anthracite-consuming states are ready to put all of their impetus behind federal regulation of the anthracite industry. It is regarded in Washington as being quite significant that the second Pinchot conference should have succeeded so well just at a time that it had been generally concluded that it constituted another fiasco. When a group of state executives representing different political parties and whose interests conflict sharply at many points are able to get together on a common program such as was outlined at the last Pinchot conference, it is evident that a new force looking to federal regulation has been unloosed.

The introduction by Representative Treadway of a bill dealing with the quality of anthracite and with its distribution was expected. While it was not known that Mr. Treadway contemplated the introduction of this bill, it was expected that someone from New England would sponsor legislation of that type.

In this attitude, however, New England has the warm support of the radicals, and even some of the conservatives, from the Northwest. Apparently the public in those sections is clamoring for some control over the anthracite industry. The bill, however, indicates a narrow and provincial spirit in that it does not include bituminous coal. It is very easy to observe that the author of the bill is looking at the problem from a local instead of a national point of view.

In conformity with the message of

the President, the administration leaders apparently have no thought of favoring drastic action dealing with the coal situation. Judging from the developments of the past week, however, the initiative is to be seized by a New England-Northwest coalition. It happens that these members are in a position to obtain consideration for legislation even if they may lack the strength to carry it through to final passage.

Warns Smokeless Men Against Meddlesome Legislation

Addressing the annual meeting of the Smokeless Coal Operators' Association of West Virginia, in Washington, Dec. 13, Senator David A. Reed, of Pennsylvania, denounced governmental meddling with business.

Senator Reed criticized various proposals for the regulation of business, including legislation aimed at the coal industry. He warned the bituminous coal operators to keep close watch of legislation relating to the coal industry. He said that while the most discussion relates to regulation of the anthracite industry there are many members of Congress who do not realize that conditions in the bituminous and anthracite industries are different.

Roderick Stephens, chairman of the Government Relations Committee of the National Retail Coal Merchants Association, also spoke briefly, emphasizing the need of greater co-operation on the part of the entire coal industry.

About 100 members attended the meeting and unanimously indorsed the Mellon income-tax plan.

Robert H. Gross, of Boston, was re-elected president of the association. Mr. Gross was unable to be present because of a sudden illness. Oscar M. Deyerle of Bluefield, W. Va., presided in his absence while George Wolfe of Beckley, W. Va., acted as secretary.

Officers elected besides Mr. Gross were: William C. Atwater, of New York City, first vice-president; W. P. Tams, Jr., of Tams, W. Va., second vice-president, and George R. Collins of Charleston, W. Va., treasurer. Members elected on the board of governors

were: Pocahontas district, T. F. Farrell of New York, and L. R. Page, Jr., of Philadelphia; Tug River district, John C. Steinbughler, of New York City, and George R. Collins, of West Virginia; New River district, G. H. Caperton, of Charleston, W. Va., and M. L. Garvey, of Winona, W. Va.; Winding Gulf district, W. P. Tams, Jr., of Tams, W. Va., and P. M. Synder, of Mounthope, Va.

Mr. Farrell, in presenting a report from the transportation committee predicted that the Interstate Commerce Commission would approve the proposed through rates on smokeless coal to New England and other Eastern points as submitted to the commission during the previous week.

Charge Unfair Trade Methods To Midwest Retailers

Unfair methods of competition in the sale and distribution of coal are charged in a complaint by the Federal Trade Commission against the Illinois & Wisconsin Retail Coal Dealers Association, including its officers and members. The association is composed of retail coal dealers of Illinois and Wisconsin. The complaint recites various methods by which the association and its members enforce its co-operative scheme of boycotting so-called "irregular" or "illegitimate" dealers, such dealers being determined by the association as being outside of its definition of a retail coal dealer.

The complaint further states that the association's acts constrain producers and wholesalers of coal to confine the distribution of coal in respondents' so-called "regular channels" and to prevent so-called "irregular dealers," co-operative associations and groups of purchasers from securing coal at wholesale or from any other source than from "regular" or "legitimate" retail coal dealers, thereby unduly obstructing and hindering free competition in the distribution and sale of coal in the association's territory.

J. B. Sanborn & Co., publisher of the "Coal Dealers' Blue Book," is listed as a respondent in the complaint, and is charged with co-operating with the coal association in its undertaking to confine the sale of coal in its territory to their so-called "regular" dealers. Others individually named in the complaint are Russell H. Jones, R. B. Her-ring, C. S. Dodge, I. L. Runyan, W. H. Baethke, W. J. Dambold, E. H. Keeler, A. H. Holcomb, R. S. Hunter, H. E. Eastman, J. H. Wall, F. A. Young, W. J. Baker, H. B. Gaines, R. C. Wagner, Jr., P. F. Irwin, W. S. Harwood, C. R. Burnton, J. V. Tapper and Joseph Rademacher.

Illinois Operator Suggests Government Control Plan with Teeth in It

H. C. Adams Would Have Coal Board Fix Prices and Restrict Output to One-Sixth Above Consumption, Aiming at 20-Day Working Months and Stability

An outline of a government-control plan to remedy the ills of coal has gone into the mails for Congressmen and others, from the office of H. C. Adams, president of the Peerless Coal Co., of Chicago, a veteran operator. It is called "Suggestions for the Solution of the Bituminous-Coal Problem" and was worked out after much thought and consultation with other experienced coal operators of the Middle and Far West.

Under this plan a permanent government commission of eleven with a minority of coal operator members would try to restrict production to about one-sixth in excess of the normal consumption of the country. This would be attempted (1) by licensing all producing mines, (2) by passing upon the necessity of opening any new mines, and (3) by requiring substantial and therefore expensive construction of all new mines and possibly by requiring them to operate from the first on a retreating basis.

The commission would gather and publish facts about coal and would "fix selling prices when production and consumption were close together," but would take no part in wage negotiations. Mr. Adams also firmly recommends the incorporation of the United Mine Workers of America. The complete set of "suggestions" follows:

"The Fact-Finding Commission developed, in their investigation, a number of conditions having to do with the general demoralized condition of the coal business. The report would indicate that one of the greatest, if not the greatest factor is over-development, which is by no means an unsolvable problem, and the writer, in offering the plan hereinafter described, is doing so in the belief that Congress has the power to change existing laws and to make new ones to suit conditions.

"Over-development of the industry cannot be regulated by the industry itself, and so long as unrestricted development is continued, the coal situation will be chaotic in every sense.

"The following plan is offered as a basis to govern future development and to secure the maximum of safety, economy and conservation.

"A commission to supervise the coal industry should be appointed by the President of the United States, and should consist of eleven members, as does the Interstate Commerce Commission, three or four of whom should be skilled coal mine operators, presumably one from the East, one from the central East, one from south of the Ohio River, and one from the Far West—the coal members should be in the minority. The other members should be selected business men. Their term of appoint-

ment should be not less than seven years.

"The commission should receive from railroads and coal companies statistics covering all matters pertaining to the development, production and marketing of coal and to cars in which to move it.

"*Method of Licensing New Mines.*—A company owning coal acreage desiring to open a mine should file application with the commission above described. With all statistical facts before the commission it would be easy to determine whether further development was justified and whether or not the applicant could develop new business or further divide the district's current business. When coal consumption reached five-sixths of the developed capacity of all mines, then further development should be authorized and such ratio maintained.

"It is obvious if five-sixths of the available supply of coal were consumed, the flow of coal must be on the basis of about twenty days of mine operation per month, and that the domestic user must take in a large part of his coal during the summer months, and that the steam consumer must store in the summer a surplus for winter. In other words, each month's supply of coal must be shipped in approximately twenty days, and if not consumed must be stored. The above distribution

Hoodoo

An old woman with a bad eye aided and abetted by a Greek mystic in a greasy Chicago "lunch" nearly shut down No. 2 mine of the Union Pacific Coal Co. at Hanna, Wyo., on Dec. 13. A few days before the 13th the old woman with the bad eye had a dream—she saw No. 2 blow up on the 13th! Hanna heard all about it over the back fences and snickered—outwardly. Then came a Greek miner back from a Chicago visit. He had been in a restaurant in Chicago eating "whit cacks, cup coffee and pits oppla pie" and got a prophecy—so he said—from the mystic waiter that No. 2 mine was going to blow up on the 13th! Hanna heard it—and didn't even snicker. The morning of the fateful 13th, 20 loaders out of 110 went down. The evening of the fateful 13th the 20 came up. That's the whole story, except that Gene McAuliffe, president of the coal company, says the old woman with the bad eye and the Chicago whit-cack mystic cost the company a thousand dollars.

would obviate the necessity of increasing railroad equipment, as car supply is adequate if kept in service.

"This regular movement would permit the railroads to handle the business in a much more satisfactory manner to all concerned, and as coal and transportation are so closely allied, any plan that would help one must of necessity help the other.

"Wage-scale negotiations should be conducted as now, or if some better plan between the operators and miners could be devised it could be accepted, but the commission should take no part in such negotiations.

"Prior to the expiration of a wage contract the commission should make a public statement by districts and states of the rates of pay, days worked, days available and such other information as would be useful.

"In order to further stabilize the industry and make contracts between the operators and miners enforceable, labor unions should be incorporated.

"All new development of mines should be made on government or state plans, and full and careful consideration should be given to what is known as the retreating system of operating mines. This means the entries or haulageways are driven to the boundaries of the properties before room development commences. This plan contemplates the removal of practically all coal from the seam. It is a conservation measure and should be given consideration.

"It would be advisable to compel the purchase of the surface as well as the coal underlying it. This would permit of the retreating system and would eliminate the contentions arising out of subsidies.

"All mine buildings and shafts should be of fireproof construction, and particular attention should be paid to the shaft bottom. Sufficient supports should be left in to insure the mines' perpetual safety. Hoisting apparatus should be equipped to insure safety.

"Such restrictions would discourage all but competent, well-financed companies from engaging in the business, and would not only stabilize the industry but guarantee maximum safety to employees and conservation of coal measures, of which fully 35 or 40 per cent is now wantonly wasted.

"A glance at the financial condition of a great many railroads, utilities, packers, and others that are under government control or supervision discloses a reasonably satisfactory healthy business condition.

"It would be necessary for the commission to fix selling prices when production and consumption were close together, and they should be empowered to do so, allowing the producer a fair return on his investment. Prices could be easily arrived at by using average cost and quality, and requiring a standardized system of cost accounting.

"The commission should from time to time publish such facts concerning the working time of mines, earnings of the men, cost of coal, realization, and other facts which they may deem important for the public to know."

"Governors" Parley Directs Pinchot to Draft Hard-Coal Bill and Push It

Preus and Representatives of Governors of Four Other States Attend
—Pennsylvanian Dodges Questions Before Newspapermen—
Measure to Be Introduced in Congress in January

The second "conference of governors" called by Governor Pinchot of Pennsylvania to consider his suggestions for the regulation of the anthracite industry saw Governor Preus of Minnesota and four representatives of other governors, besides Mr. Pinchot, at Harrisburg on Dec. 13. They discussed the Pinchot outline of a federal bill and his proposed compact of states plan and authorized the Pennsylvania Governor to complete both and mail copies to the governors of the thirty anthracite-consuming states invited to the two conferences.

As matters now stand Governor Pinchot is approximately where he was when he first called the conference in November. At that time some of the governors asked to attend suggested that he mail to them any suggestions he might have. After the first conference he did mail skeleton drafts of his plans and now within a few days he will mail a complete bill, which he promised the conference he would have introduced in Congress, and a complete compact. On the other hand the Pennsylvania Governor lost no ground at the second meeting, for while neither of his suggestions was adopted it was unanimously agreed that something might be gained from a study of the completed idea and there was a decided sentiment among the half dozen conferees that federal legislation is needed.

ADOPT PREUS-PEARSE MOTIONS

Two motions were adopted by the conference. Governor J. A. O. Preus, of Minnesota, offered one which authorized Governor Pinchot to send the complete draft of the federal bill to all the governors of the anthracite-consuming states and that the Pennsylvania executive urge the governors to use their influence upon their Senators and Congressmen to support the measure. The other motion, made by F. M. P. Pearse, secretary to Governor Silzer, of New Jersey, provided that the compact be fully drafted and forwarded to the governors and that Governor Pinchot be empowered to call upon the governors for such assistance in its preparation as he may see fit.

In addition to Governors Pinchot and Preus and Secretary Pearse, there were in attendance at the conference Cyrus Locher, Director of Commerce, of Ohio; Dr. Frank J. Monaghan, Health Commissioner of New York City, representing Governor Smith of New York, and W. E. Snider, of Michigan.

It is not believed there will be further meetings. At least, nothing was said at the conference of Dec. 13 about reconvening the representatives. Governor Pinchot has said repeatedly that

he will have the federal bill presented whether the other states go along with him or not, and while there is little to indicate that many of the states will co-operate with Pennsylvania in trying to adopt the compact, Governor Pinchot is said to have hopes that some of the states will accept this part of his plan. Those that indicate that they favor the compact can be got into line without a meeting, it is said at Harrisburg.

Only one suggestion was made at the second conference in reference to the Pinchot suggestions, and that came from Mr. Pearse, who said that wholesale coal dealers should be licensed under the state regulatory plan.

The same opposition that was manifested at the first conference to the compact developed at the second and it was led by the representatives of New Jersey and Minnesota. In fact these two did most of the talking with Governor Pinchot, the other three remaining quiet through the two-hour debate on the measures.

INVITES PREUS BEHIND BARN

Governor Preus asked whether, if the Pennsylvania Legislature were in session and a bill making the anthracite industry a public utility were introduced, the Legislature would pass it. Governor Pinchot replied to this: "In the presence of newspapermen, I must take the advice of counsel and refuse to answer. However, if you come out behind the barn I can tell you all about it." The Legislature of 1923 defeated a bill, sponsored by Representative Burns, of Philadelphia, which would have made the industry a public utility.

J. J. Walsh, secretary of the State Department of Mines, at the opening of the conference presented figures to show the findings of his inspectors who examined more than 1,000 carloads of anthracite at the mines. The reports showed that from 10 to 16 per cent of bone and slate was found in the coal. He defended the certification law of Pennsylvania and spoke in behalf of the proposed compact. The federal bill was discussed by Philip S. Wells, a deputy Attorney General, and Harold M. Evans, Philadelphia, who aided in drafting the measure. Neither of the Pinchot plans was taken up in detail and when the talk was leading nowhere Governor Pinchot brought it back to the matter before the conference.

"The principal thing, it seems to me," remarked Governor Preus finally, "is to get the federal legislation before Congress as soon as possible."

Governor Pinchot agreed with him and said it should be introduced early in January. The two motions were then offered and quickly adopted.

Lawmaker's Impression of Hard-Coal Legislation

"You will hear the anthracite industry discussed in Congress this winter out of an immensity of ignorance, and I advise you to watch closely what is done, because the fact is the majority of men who will vote upon that question do not know that there is any difference between the conditions under which anthracite is produced and the conditions under which bituminous coal is produced."—Senator Reed, of Pennsylvania, before the Smokeless Coal Operators of West Virginia, in Washington, Dec. 13.

O'Gara Coal Co. Wins Suit

A verdict for \$82,801 was recently rendered against the Chicago, Milwaukee & St. Paul R.R. by a jury in the District Court of Douglas County, Neb., in an action brought by the O'Gara Coal Co. for alleged violation of contract.

The contract, entered into Sept. 2, 1920, covered the entire output of the O'Gara Coal Co.'s No. 11 mine, the output not to exceed 1,500 tons daily nor to fall below 1,350 tons, at an agreed price of \$4 per ton, the damages sought being based upon alleged losses incurred by the coal company because of the failure of the railroad to accept full tonnage covered by the contract during its life of seven months.

Judge Troup, who presided, in his instructions to the jury held that the railroad company, inasmuch as it used a larger tonnage of coal daily than that specified in the contract, could not rely upon 'unusual conditions' as a defense.

The coal company sued for \$165,602.

Silzer and Ritchie Repudiate Pinchot Plan

Governor Silzer, of New Jersey, and Governor Ritchie, of Maryland refuse to have anything further to do with Governor Pinchot's plan for concerted action by anthracite-consuming states to bring down prices. In an address before the Board of Trade and Transportation at New York City, Dec. 12, the New Jersey Governor characterized the Pinchot proposal as impractical and again put the main job of housecleaning the industry up to the State of Pennsylvania itself.

Governor Ritchie of Maryland sent a letter Dec. 12 to Governor Pinchot declining to set up "coal-distribution machinery" in Maryland, in accordance with the plan of the Pennsylvania Governor. The Maryland executive held that creation of a state regulatory commission, with consequent expense and additional officeholders, was not warranted by conditions in his state. The Pinchot plan, so far as it provides for regulation by the State of Pennsylvania, is a matter that can be left safely with the Pennsylvania Governor, Governor Ritchie wrote.

Second National Power Exhibition Proves Bigger Success Than the First

Interest in the annual show of power and mechanical apparatus held at the Grand Central Palace, New York, Dec. 3-8, was even greater than that of last year, when the first national power show was held. Exhibits covering nearly every phase of power generation, power-plant control, and fuel analysis were displayed before the engineers and interested public. The success of this year's show was helped much by the joint meetings of the several engineering societies in New York during the same week.

Naturally most of the exhibits dealt with the production of power from coal and fuel oils. There was, however, a lack of power-generating machines, such as reciprocating engines and turbines. Many of the exhibits showed full-size power plant equipment, which in many cases was supplemented by educational talks and graphic and pictorial illustrations, together with an extensive program of motion pictures.

Starting with a display of the various kinds of wood, coal and oil fuels, it was possible for one to go through the exhibition hall and follow the processes of conveying, preparing and burning the fuel to the smokestack and the ashpit. The exhibits covered every phase of power-plant equipment from furnaces, boilers, burners, control, metering and conveying apparatus to flue-gas analysis. To those following the rapid development of the power plant, new types of stokers for burning small sizes and pulverized fuel were most interesting. One could not help but see that the development of this equipment is pointing the way to the day when fuels once considered waste products and unburnable will be utilized at efficiencies as high as, if not higher than, the best grades of coal are being burned today.

CHANGE IN BOILER DESIGN

In keeping with the advancement made in stokers, there has been a change in boiler construction leading to the use of higher steam pressures, and to withstand these high pressures and high temperatures the most modern power plants are now changing and remodeling much of their equipment. To meet these conditions the valve and fitting manufacturers have designed their products for pressures up to 400 lb. and steam pressures as high as 800 deg. F.

Another interesting part of the show was the complete line of steam and power-house specialties. Many of these accessories have been designed to eliminate the human element, making almost everything about the power plant automatic. In this way plant operation may be carried on at the highest point of efficiency. Many of these appliances may be interconnected and co-ordinated with the rest of the system so as to regulate the furnaces,

boilers, dampers, fans, etc., to obtain the best operating conditions automatically with changes in the load.

A novel device applied to coal and material conveyors on exhibit was the Merrick conveyor weightometer, manufactured by the Merrick Scale Manufacturing Co., of Passaic, N. J. This machine will weigh and record the weight of any material while in transit over a belt, bucket, or pan conveyor, without interrupting the flow.

Another exhibit of interest to the man who must convey coal was the Sandvik steel belt conveyor, made by the Sandvik Steel Co., New York, which was equipped with scrapers for unloading any portion of the material at any required location along the line.

The exhibit of the Fuller-Lehigh Co., of Fullerton, Pa., showed complete details of a coal-pulverizing plant, with pulverizers and blowers for various types of furnaces and boilers.

The Pyramid grate, manufactured by the Pyramid Iron Products Corporation, of New York, showed a novel design of grate, permitting a 30 per cent air space without the loss of even the ordinary small size fuel through the grate.

For emergency and auxiliary power supply the mining man found much interest in the fuel-oil engines of the Climax Engineering Co., of Clinton, Iowa. Several drives of this type are already installed in some of the coal mines for emergency power supply in case of fire or accident.

To the tippie, breaker and washery man, the Smith type friction clutch, made by the Hill Clutch Co., offers a solution to the driving of coal-preparing machinery from a main-drive shaft, or where machinery must be started slowly or inched.

For the mine shop, office, club and recreation hall, the Fellingner & Hebard Co., of New York, had an interesting exhibit of the Bradley washfountain, an easily installed fixture, which better meets the requirements of sanitation, economy and satisfaction than the usual washstand.

Coal Consumption and Power Output of Utilities Higher

Electric public-utility plants consumed 3,546,831 net tons of coal during October, according to a report just issued by the U. S. Geological Survey. This compares with 3,172,534 tons consumed during September, according to corrected returns.

Fuel oil consumed by public-utility plants in October totaled 1,426,620 barrels, compared with 1,335,356 barrels in September. The average daily production of electricity by public-utility power plants during October was 160,400,000 kw.-hr., compared with 151,200,000 kw.-hr. in September.

19-Year Mine Has No Strike, Fatality or Shutdown

Production of over 2,500,000 tons of coal without a fatality, a strike or shutdown and nineteen years under the same active management is the record of the Gay Coal & Coke Co., of Logan, W. Va., according to R. M. Lambie, chief of the West Virginia Department of Mines. The company opened the first mine in the Guyan Valley and made its first shipment of coal on Thanksgiving Day in 1904. Tom Gilpin, one of the three teamsters that helped to load the first railroad car at the mine, is still with the company.

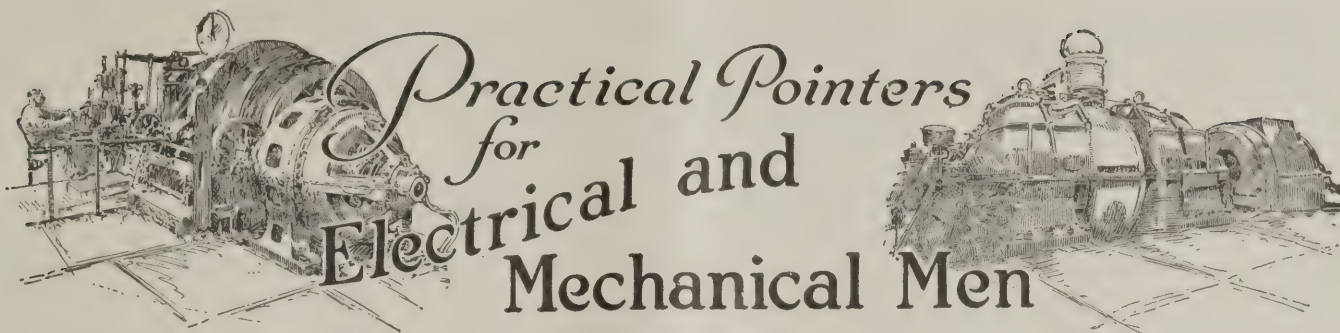

H. S. Gay, Jr., superintendent, attributes the achievement of this record to (1) Strict compliance with the mining law and company rules; (2) unusually good roof conditions; (3) when bad roof has been encountered, all timbering has been done by company men under the supervision of an official; (4) employees have been mostly native West Virginians, who seem to acquire proficiency in mining easily; (5) full co-operation by the men; (6) all operatives of electric locomotives and mining machines served their apprenticeship in the mine; (7) efficient signal system that gives the exact location of all electric locomotives at all times; (8) all transportation is handled as on a modern railroad; (9) proper methods of handling, transporting and using explosives.

Among the many employees of this company during its nineteen years of operation have been Jack Dempsey, world's champion heavyweight boxer, and Don Chafin, Sheriff of Logan County, West Virginia. Both were employed as miners.

To Discuss Mining Industry

Forecasting of business booms and slumps will be the topic discussed at the annual meeting of the American Statistical Association, to be held Friday, Dec. 28 at the New Willard Hotel, Washington.

The program of the mining session, which begins at 2 p.m., Dec. 28, presided over by John Hays Hammond, is as follows: "Fluctuations in Mineral Output," George Otis Smith and others, U. S. Geological Survey; "The Effect of New Technique on the Past and Future Production of Petroleum," Joseph E. Pogue, consulting engineer, New York City; "The Metals," E. H. Robie and F. E. Wormser, assistant editors, *Engineering and Mining Journal-Press*; "The Bituminous Coal Industry in Prosperity and Depression," D. L. Wing, consulting statistician, Washington, D. C., and F. G. Tryon, U. S. Geological Survey. Discussion will follow.

Test for Adhesiveness Of Friction Tape

A much-used specification for determining the adhesive strength of a tape is: "The adhesion between adjacent layers of the tape shall be such that when a strip of tape 2 ft. long is taken from a roll and wound upon a mandrel 1 in. in diameter, under a tension of 10 lb. per inch of width at a rate of 30 in. per minute and allowed to stand for three minutes with the weight attached, a weight of 4 lb. per inch of width shall not cause the plies to separate at a rate greater than 30 in. per minute. The test shall be made at a room temperature not less than 21.1 deg. C. or 70 deg. F. nor more than 23.9 deg. C. or 75 deg. F., the sample having been kept within these limits for at least 30 minutes immediately preceding the time of testing.

"The mandrel shall be so free in its bearings that a weight of 1 oz. will cause it to revolve freely when suspended from a cotton string wound in a single layer on the center of the mandrel."

The conditions of such a specification must be carried out scientifically and exactly in order to obtain reliable data on adhesiveness. A variation of any one of the conditions will entirely alter the results. This essential property of a high-grade tape—adhesiveness—cannot be determined by any casual or superficial means, such as sense of touch, etc.

How an Easy Repair Was Made To a Synchronous Motor

A synchronous motor driving a large air compressor recently gave us trouble. This motor is first of all started as an induction motor and after being brought up to speed it is changed over to a synchronous motor. For some time this motor was becoming more difficult to start, until finally it was impossible to bring it up to the correct speed before changing over to a synchronous motor. The difficulty was that the squirrel-cage starting winding had become loose between the poles, being built into the field poles.

To make a quick repair some soft solder wire was hammered into thin sheets and inserted between the bolted sections of the squirrel-cage winding. When the bolts were tightened the

sheets of solder worked into the rough surfaces at the contacts and formed a good conducting path from one section of the winding to the other. In this way the resistance of the starting winding was lowered so that it was easy to bring the motor up to full speed before changing over to a synchronous motor.

SHOP FOREMAN.

The illustration also shows how the wires are finally brought together and how the outer sheathing may be closed in to complete the splice. Usually the cable will be saturated with wax or some kind of compound to prevent moisture from entering.

W. VIRGINIA.

Trouble That Was Not Trouble

On the afternoon of one of the numerous holidays our company has had recently one of our electrical men went to the power-converting substation at the mine where he was employed and tried to start one of the two rotary converters there and found something that puzzled him and some of his superiors for some time.

These two rotaries were driven by alternating current fed to them by two separate banks of step-down transformers. To start either machine it is first of all necessary to close a switch that puts power on its bank of transformers. Our electrician closed this oil switch in the usual manner but noticed that the ammeter on this circuit gave a sudden indication of very high current just as the switch was closed. In fact, this current was about twice full-load current for the transformers. Without going any further with the operations necessary for starting the rotary connected to these transformers he tried the same thing again, with the same results—a high initial inrush current. Next he tried the oil switch for the other rotary converter, but it showed only a small initial inrush current.

From these observations it appeared as if there was trouble with the first bank of transformers. It was easy to come to this conclusion because the transformers were located outside and had been transferred to the mine after lying idle in another section of the region for over a year.

It was finally decided that there was a breakdown in the first bank of transformers and this break flashed to ground only when the transformers were thrown on the line; the flash, occurring in the oil, was quickly smothered almost as soon as established. Preliminary investigation of the transformers exposed no sign of a breakdown so a "Megger" was obtained and all the transformers tested. The tests showed

Splicing 3-Conductor Cable

The good workman is always endeavoring to make his last piece of work better than the previous one, but he is always ready to try out a new method if it looks practical and will accomplish something in a little better way than it was ever done before. Therefore I wish to submit to *Coal Age* readers the following method for splicing a three-conductor cable:

First of all the sheathing is split open in a line running with the cable. This sheathing is opened up and carefully handled so as not to be torn or broken. The three conductors are then exposed and the hemp or jute filler removed. Each conductor is next cut so as to be joined as shown in the illustration. By arranging the splices in the individual conductors as shown, a neat splice can be made in the cable.

SPLICE FOR THREE-CONDUCTOR CABLE

Each conductor is carefully spliced and taped before the outer envelope is closed around to complete the splice.

In splicing the individual conductors much care should be taken because the joint should be electrically perfect and mechanically strong and at the same time should not be bulky. The upper part of the illustration shows how the rubber insulation has been tapered off and also how the taping is applied. Note that the outside diameter of the conductor at the joint is no larger than the main section of the same wire.

that the particular bank of transformers supposed to be in trouble showed a higher resistance test than the other.

This beclouded the matter still further and by night time nothing new was found. The next morning the chase after the trouble was resumed and by starting from the beginning of the supposed trouble it was found that the high initial inrush current happened depending upon the instantaneous value of the voltage of the line wire that the meter was in when the oil switch was closed. Both banks of transformers showed high and low initial inrush currents depending upon the instantaneous voltage of the line and the quickness with which the switch was closed.

ELECTRICAL ENGINEER.

Starting a Synchronous Motor-Generator Set

We recently experienced some trouble in starting one of our motor-generator sets and after careful examination found that all the electrical circuits and everything in connection with the operation of the machine was correct, yet it was not possible to bring the machine up to speed before throwing over on the full line voltage.

This motor-generator set consisted of a synchronous motor and a 250-volt direct-current generator. When the motor was thrown on the starting voltage it would start without much hesitation but it would not come up to speed sufficient to throw over on the running voltage without an abnormal initial-current inrush.

It so happened that this synchronous motor was excited from the direct-current generator which it drove and as the generator is started it feeds current into the synchronous field of the motor. The result of this action was that the exciting current built up a field in the motor which exerted a dragging effect upon the revolving element. By putting all the field resistance into the field circuit of the motor we were able to bring the machine up to speed on the starting voltage. After this it was possible to put the machine on full running voltage without any difficulty.

SUBSTATION.

Effects Produced by Electric Current

When electric current flows in a given conductor it may be used to produce one of several effects. Principally these are, chemical, heating and magnetic.

The first—chemical effect, also known as electrolysis—takes place when a current is made to pass through a liquid containing a metal in solution, or where a liquid and metal come in contact with each other. In the usual method of applying electrolysis the current causes metal to be deposited on a metallic object suspended in solution. This is known as electroplating.

The second effect—heating—is the

transformation of electrical energy into heat energy, which takes place when current flows through a conductor. Generally the conductor used for making heating appliances is made up of wire or grids having a relatively high resistance. A soldering iron is a typical example. A more common use of the heating effect of electrical current is that of the incandescent light. In the electrical circuit of the lamp the current passes through a filament of high resistance and this filament becomes heated to incandescence, thus giving off light. Electric welding is another application of the heating effect of electric current.

The third and perhaps most important effect produced by electric current is magnetic. A conductor carrying electric current has around it what is known as a magnetic field. To strengthen this field it is common practice to wind the conductor in the shape of a coil and place inside the coil an iron core. This iron core tends to intensify the effect of the magnetic field. The electric motor is an important illustration of the application of the magnetic effect of electricity. It is the attraction and repulsion of the magnetic field in the armature and the field poles of electric motors which makes possible the operation of the motor.

Finding the Cause of Armature Burn-outs

It is sometimes difficult to locate troubles with electrical equipment and sometimes hard to remedy them but here is one that was remedied very easily—by eliminating the cause.

One of our locomotives was always giving us armature trouble. I can remember many a day when the electrical workmen labored hard during the day to change armatures in this locomotive and then again late at night to repair the armature.

After considerable and careful inspection of all the equipment on this locomotive the trouble still persisted. Some time later another locomotive was put into this section of the mine and the troublesome one was transferred. Soon the new locomotive began to develop trouble and the old locomotive operated in another section with little or no trouble.

At first we were at a loss as to what was causing the trouble, but one day near the noon hour I was passing through the section in which we were having all this trouble and I went over to see how things were going. When I got near the locomotive everything appeared to be as normal, but I waited around a little while and soon noticed smoke coming from the resistance. I immediately started to investigate the trouble, and much to my surprise I saw a piece of burned bread on the resistance. The motorman had locked the wheels of the locomotive with the brake and had turned on the power to heat the resistance to toast his bread. This was the cause of our burned com-

mutator segments, burned-off armature coils and high cost of repairs. The cause was removed; the motorman is working for another company now.

MINE ELECTRICIAN.

Keep the Power-Demand Charge Down

To obtain the advantage of a high load factor, or, in other words, to keep our maximum demand as low as possible, at one of our mines where we are purchasing power we have tried to do whatever work we could at off-peak times.

Quite naturally we laid out one of our largest pumping stations so that pumping could be done at night. In order to do this we made a large sump area and could hold water in this sump until night time during the usual mining high water season. Somehow or other the men at the mines could not get the idea of pumping at off-peak times and the result was that the pumps were started and run when we had our other peak loads.

After considerable time and education on the subject at the mines, we thought we had everything understood, but occasionally someone would start the pumps to test them or inspect them at the wrong time.

Our work seemed hopeless, for the pump demand always seemed to be on our monthly power bills. One day a happy thought occurred to us and we put a time switch on the control. This time switch is set to cut off power to the pumps except during the night time. Now our troubles are over and the saving on the power bill is about \$200 a month.

ENGINEER.

Heating of Conductors In Mines

Can you tell me where I can get some information regarding the heating of rubber-covered single conductors, double braided, carrying 3-phase A.C. when in iron or steel conduit? The problem is fully covered for lead cables, but I have been unable to find anything on three individual conductors.

The problem seems to be impossible of purely mathematical solution, due to the fact that some of the heat is undoubtedly carried from the wire to the surrounding iron by convection. Figures neglecting the convection currents and considering the body of air inside the pipe as dead, give results entirely too high to be of any value.

As an example, with three wires carrying 440-volt 3-phase 60-cycle current of 200 amperes in 2-in. conduit in the mines where the ambient temperature is fairly constant at 55 deg. F., a 1/0 wire is sufficiently large for voltage drop, but will it be sufficiently cool at the above temperature to protect the rubber insulation?

Problems In Underground Management

Timbering Methods That Will Save Lives, Coal and Lumber

Timber Should Be Recovered—Mistake to Forbid Use of Axe in
Removing Props—Protect Men in Pitching Bed
by Use of Battery of Lagging

BY JAMES GRAY
Newcastle, Washington

In drawing pillars, or in longwall retreating, all timber that can be safely recovered should be withdrawn as the work proceeds. If in removing pillars the gob or waste is filled with props and cogs, the weight of the roof is thrown down on the coal face, so that the roof tends to break over the top of the pillar, thereby making the roof dangerous to work under. This also breaks the coal, increasing the percentage of slack.

All timber should be drawn to within 12 or 15 ft. of the coal face in order to allow the roof to cave in. Such roof falls make the mining of coal much easier and provide conditions favorable to the production of a larger percentage of lump. Cogs also should be drawn if possible, or, better yet, they should not be erected unless absolutely necessary, and then only as skeleton or empty cogs. When they are not filled they can be more easily taken out. The idea is to allow the roof to cave in behind, thereby taking the pressure off the coal face. I have had charge of mines in Scotland, Nova Scotia, Canada and Australia where every prop was pulled out of the waste which could be safely removed, and much of this work was done on contract.

CHOPPING OUT CAP-PIECES

All props were set with a good cap-piece on top so that when the prop had to be drawn this cap-piece could be chopped off with a good sharp axe. Sometimes a wedge, made for the purpose, was used for splitting the cap, if the roof was not too heavy. If the roof was weighty, we dug around the bottom of the prop or split off as much of the cap-piece as we could with safety; then a prop puller was used to pull out the timber. Only experienced men were employed for recovering props and cogs.

The method we adopted was as follows: After the first lift of coal was taken off the pillar, we set our first row of props—good stout timbers with cap-pieces 4 in. thick by 9 in. wide by

18 in. long. We kept putting in rows of props every 4 ft. apart until we had four rows in line. Whenever there was room for the fifth row we pulled the first row of props and moved them behind the last row. We kept on doing this, always keeping four rows of props behind the miners, until the roof took its first break and came down. This took the weight off the face.

After the first break we used only two rows of props, always advancing the back row as soon as room was made for them. We did not set the props so tight that we would have trouble in pulling them. If one chanced to stick, we generally got it out by the use of the prop puller, and seldom did we have to shoot it out. When we had occasion to put in a cog we built it up like a cage, entirely without rock. The foregoing work was done in seams that were nearly flat.

On a seam pitching 25 deg. or more, more care would have to be taken. This could be done by placing behind the miners a battery which need be only

3-in. x 12-in. x 9-ft. timber laid against the second row of props to keep any material from falling down on the miners at work. I feel confident that all or nearly all, the timber could be taken out of a pitching seam as well as a flat seam, and for this reason: The props need not be set at right angles to the full pitch. Set a little away from the perpendicular to the seam it would not be hard to dig around the bottom on the front side of the prop and pull it out by the use of the prop puller.

WHY THE DIFFERENCE IN LAWS?

This reasoning is true both for anthracite and bituminous mines. Rule 55 in the anthracite mine law, which prescribes that props shall be blasted and not cut out, should be changed to agree with the terms of the bituminous mine law. I fail to see sufficient difference in conditions to justify the variation in the enactments.

The mining laws should be amended so as to make it compulsory to pull out all timbers in coal mines where it can be done with safety, but the law should be so worded that operators would be allowed to employ only practical and experienced men to do this kind of work. Much timber and cost would certainly be saved thereby. In pulling pillars on a pitching bed, I would add one row of props to the two rows I have recommended for use with a flat bed, especially if the lift of coal is to be taken up on the angle as a wing, instead of across the top of the pillar.

FIG. 1

FIG. 2

FIG. 3

FIG. 5

FIG. 4

FIGS. 1 TO 5—HOW TO TIMBER ROOF SYSTEMATICALLY

Fig. 1 shows room and pillar. Pillar of working on left of Fig. 2 is just commencing to be drawn. Four lines of props are left, the fifth line being set by props progressively withdrawn from the first line. In the room on the right is shown the method adopted after the first break. Here only two rows of props are used. On the right of Fig. 3 a timber battery protects the miners. Fig. 4 shows the rib being mined on a slope and Fig. 5 a skeleton or unfilled cog.

McAuliffe Increases Safety in U. P. Mines; Installs Loaders

A number of mechanical and management changes now in process of development in and around the Wyoming mines of the Union Pacific Coal Co. are expected to increase safety as well as the output of the properties. The installation of mechanical loaders, which has already drawn criticism from inspired sources, is one of the improvements. Eugene McAuliffe, president of the company, recently explained what is going on in the mines thus:

"A double reinforcement of past safety effort in this company is about to be put into effect. On Oct. 1, A. W. Dickinson, an engineer experienced in the operation of coal mines and the conduct of safety work, was appointed safety engineer, in charge of accident-prevention work. Mr. Dickinson has adopted a new slogan, 'Make It Safe,' as keyword of the safety department.

"The Union Pacific Coal Co. has for years maintained first-aid and rescue crews, keeping up the work of training men, providing new and modern apparatus, etc. At the present time many items that tend to make mine work safer are either complete or are under way, included among which might be mentioned the preparation and posting at mines of ventilation maps which show the direction of all air currents, a definite reading of the volume of air passing through the last crosscut on each entry made and recorded daily, special men being assigned to this work.

GAGES RECORD AIR PRESSURE

"Recording gages actuated by clock-work have been ordered for every mine fan. They will provide the mine foremen with a positive record of ventilation during each 24-hour period, and this record will be inspected by the foreman before the men enter the mine each morning, and the fan chart for the day will be filed for record. Where coal dust is a hazard, the roadways and rooms will be sprinkled twice as frequently as heretofore and rock-dust barriers are being installed to localize any accident that might occur.

"In addition, dry mines are being equipped with sprays to moisten the air entering the mines, and the use of black powder is entirely stopped. As a preventive of fires all unnecessary accumulations of wood and other combustible foreign matter have been taken out of the mines and fire-prevention appliances have been installed in each inside hoist room. The outside fire-prevention safeguards have been reinforced. All mines known to generate explosive gas will be put strictly on an electric-lamp basis. As soon as the lamps can be obtained, open lights will be eliminated.

"At Hanna No. 2 a denial of the smoking privilege led a few men to leave their work, but the substantial men have expressed their approval of the additional safety afforded them by the entire elimination of open lights

and matches. Where fans at mines making gas were electrically driven the motors have been disconnected and the more reliable steam-engine drive substituted, though the cost of power has been doubled or trebled thereby. Of late every safety lamp used for mine inspection is magnetically locked, requiring the fireboss to go to a lighting station before he can open his lamp for relighting. For the prevention of fires caused by short-circuits due to falls inside the mine electric circuit breakers have been purchased and will be installed as rapidly as possible.

"The Union Pacific Coal Co. management expects gradually to substitute mechanical loaders for the present method of hand loading within the mines, not in order, as has been suggested by a certain mine superintendent now much talked of in the public press, to make 'mindless machines of its employees' but instead to translate the job of producing foot-pounds with a shovel into that of operating a machine where the man can use his brains more and his back muscles less, and where the steel fingers of the loading machine will take the crushing that is now the lot of human fingers.

"In substance, the Union Pacific Coal Co. is officered by men who do not subscribe to the theory that 80 or 90 per cent of its employees lack the capacity of clear thinking and the ability to do more than shovel coal into a pit car."

Why Coal Mines Explode

In addressing the Rocky Mountain Coal Mining Institute D. Harrington declared that the ignition of methane is the initiating cause of probably 75 per cent of the coal-mine explosions in the United States, yet only in rare instances is there a widespread disaster in which methane furnishes all the fuel. Coal dust alone supplies the starting

PRIMARY AND SECONDARY CAUSES OF EXPLOSIONS

Wherever there are two causes there are two defenses. Thus with electric ignition we can suppress the spark (Defense No. 1) and remove the methane or wet down the dust (Defense No. 2).

material for probably less than 20 per cent of our coal-mine explosions; on the other hand, it furnishes the propagating fuel for nearly all of the larger explosions of the present day and probably is responsible for much more than two-thirds of the loss of life which explosions cause.

Open lights have been the igniting cause of well over 50 per cent of our explosions, methane generally being the fuel, though under certain conditions coal dust can be ignited by the flame of a carbide lamp. Plain safety lamps,

chiefly in the hands of firebosses or safety men, have caused several explosions with heavy loss of life; usually the lamps have been wrongly assembled or have been otherwise misused. While electricity has been the igniting agency in but a small percentage of our past explosions, it constitutes an ever-growing menace, and it is probable that at least 25 per cent of the present-day explosions are due to electric ignition. Electric arcs are particularly dangerous when fine dry coal dust is suspended in the air. Blown-out shots have caused at least one-third of the explosions that have occurred in the coal mines of the United States and in some coal-mining regions which have numerous explosions two-thirds of them may be ascribed to blown-out shots.

Clean Out Slack in Undercut To Get Lump Coal

BY W. J. GERMAN

Technical Representative,
E. I. duPont de Nemours & Co., Ltd.

Larger coal would be obtained, less explosive would be used, labor would be saved in preparing coal for loading and danger could be decreased by reason of the lessened use of powder or dynamite if the undercuttings made by machines were properly cleaned out.

If the undercuttings are not removed the coal does not have space in which to break down and consequently the explosive cannot do as much work as it should. At a few plants the miners have long-handled flat shovels for cleaning the cut, but more often they have no such tool, and many miners figure that they would rather use an extra stick of dynamite or a few more inches of powder than scrape out the cut.

Mine officials take care that the places are cut, but only a few of them see to it that the cuts are cleaned out so that full benefit of the cutting can be derived. Thus, although the coal mines have gone to a big expense to put machines in the mines to cut a space into which the coal can give way, half of this space frequently is lost by blasting the coal before the cuttings are cleaned out. As a result, a heavier charge of explosives must be used and mining costs are necessarily increased.

THE LEGALITY of bringing Indiana mines employing fewer than ten men under the jurisdiction of the State Department of Mines and Mining was discussed at a recent conference of the members of the mining board and U. S. Lesh, Attorney General of Indiana, says Cairy Littlejohn, secretary of the board. As a result of the conference the board has decided that no action can be taken at present, but the members of the board expressed willingness to attempt to bring about action by the next Legislature which would give the board the right to bring the mines employing fewer than ten men under the jurisdiction of the department.

Discussion

Says Sentiment for Oil Fuel Already Is Passing

The consumption of fuel oil in the territory that is served by the Colorado coal operators has considerably increased during the past three or four years. The installation of oil apparatus has taken quite a hold on the general public and we now find this sort of equipment being put into industrial plants as well as in the modern home.

The arguments for burning oil are: Cleanliness—no ashes, no clinkers, no soot, no dust—and automatic control of heat units, also the belief that oil is cheaper in the long run than coal, with the glittering promise held out that oil will remain at its present very low figure.

The facts of the case are these: Fuel-oil burning does not lessen the janitor's expense, but exacts a more technical and expensive service. Fuel oil does away with dust from ashes and worry of clinkers, but in place of those you have the filmy grime of oil in your home, which is more destructive to the hangings and decorations than that of coal and I have never yet come in contact with oil-burning apparatus which does not give off a distasteful smell, and constant noise and other inconveniences which are far more objectionable than that which comes from coal.

Now in regard to the cost: It takes about four barrels of oil, which delivered at the consumer's door, will average about \$2.50 a barrel, to equal a ton of coal. In addition to this, you usually burn what is called a gas pilot, which will cost about \$2.50 per month, or electricity for motor to pump oil, which will cost about \$3 per month, and a failure of either of these delicate mechanisms to work means flooding your cellar with oil, which is a muss forlorn indeed.

In addition to this equipment depreciation, which is of a mechanism as sensitive and intricate as an automobile engine, oil-burning equipment is still in an experimental stage and its installation simply means additional plumbing bills, and outside of a few stations in temperate climates, the safety of being protected against cold snaps is very remote. Last year, during the cold snap, practically every oil burner east of the mountains failed to meet the test.

The present activity in oil fuel is without doubt due to the intensive selling campaign which has been put on by the manufacturers of oil-burning apparatus. The cost of these installations vary from \$100 to \$1,200 in residences and small apartments, and from \$2,000 up for large heating units, and the depreciation must be reckoned with the service cost.

Taking these things into consideration, and from a survey made from installations that have been adapted in some of the industries and dwellings of this state, I feel certain that fuel oil will never displace coal. Like many other things that come along, it offers flattering prospects, but we have yet to find anyone who has installed the oil and used it for any length of time that will say that it is equal to coal for the purpose intended. I have in mind one town where forty-one fuel-oil installations were made last year, and nineteen of these have already gone back to coal.

Everyone knows that the oil industry has been, and is now, subject to greater manipulation of prices than any other industry and we feel certain that an explanation of these conditions to consumers will cause them to pause before changing from coal to oil.

F. R. WOOD,
President, Temple Fuel Co.
Denver, Colo.

What the Mine Inspector Can, May and Often Will Do

A large company that had been having trouble in bringing its workmen to co-operate with it by following safe practices decided to employ a company inspector. On his first visit he found many workmen who were breaking sound safety rules. When reprimanded the miners busied themselves to do as instructed. All went well till the workmen discovered that this new safety inspector was employed by the company and not by the state. Then they

took an antagonistic attitude, and many left the company rather than do as the safety inspector desired and demanded.

This unpleasant situation has been satisfactorily met by asking the mine inspector to work with the company inspector in inducing the hard-headed workman to do as safety and the law demands. The state inspector is asked to take a hand in disciplining any recalcitrant provided he is worth the disciplining, and this he does without involving the company in any way. In this manner a good producer is made an all-around good workman, and the company profits in every way.

Many coal companies would get better results if they would take the initiative and bring problems of this kind before the state inspector, who is recognized as an arm of the law and respected accordingly. If the coal companies co-operated with the state inspector in this way safety practice would make a rapid step forward.

Pikeville, Ky. GEORGE EDWARDS.

Half Loaf Better Than No Bread

Though the application of water to the cutterhead of a machine described by John Walls, Sr., in the issue of *Coal Age* of Nov. 8, p. 710, is a most effective means of wetting coal dust and rendering it harmless, it is not necessary to continue our risky methods of dry undercutting even if we do not happen to have equipment for remodeling our machines so as to apply water in this manner.

In most cases the dust should be sprinkled as soon as the face is cut and the coal should be shot down before the dust has become dry. The coal should be sprinkled again before loading is commenced.

Gans, Pa. R. W. LIGHTBURN.

Rivals of Job

Coal operators need a wonderful sense of humor to get along. Either that, or they have been kicked so long and so often that a protective numbness deadens them to their difficulties in having to handle a hazardous and uncertain seasonal business, combining the vicissitudes of mining, transportation, and marketing, with public, politicians and labor unions making the job as hard for them as possible.

In this connection we learned the other day from newspapers that coal miners in the Hocking Valley were suffering from lack of work. A pathetic picture was painted of their deprivations, of their hardships, and of the wonderful feeling of brotherhood that glowed helpfully through their murky community like another light from Bethlehem. It was, indeed, an affecting pen picture. No work, no funds, no human aid but their own devotion and charity to each other.

Later we heard, quite incidentally (and you can wager safely that we didn't read it in a newspaper) that a certain coal mine in this same Hocking Valley had tried desperately and in vain to get its miners to work on the first day of the rabbit-hunting season. It was declared a holiday. That same week they refused again to work because it was Armistice Day.

Coal operators could make more money marketing the brand of philosophy which enables them to bear up under conditions such as these than they can, usually, by trying to keep people warm with their coal.—
Cleveland Topics.

Production and the Market

Weekly Review

Seasonal inactivity in general industry has caused less spot buying of soft coal, with contract coals moving in good volume. Weather conditions dominated the markets last week and while little improvement was noticed in the wholesale trade, retail conditions were better. With consumers' inquiries constantly increasing indications point to heavier buying in January. Reports of wage reductions in non-union mines are current and while some have been reported in various West Virginia mines no general reduction has taken place yet nor is any now contemplated by operators. The greatest activity in the soft coal market is centered in the demand for screenings.

Production of soft coal continues to decline and seems to have settled definitely into a downward trend, as the Geological Survey estimates output during the week ended Dec. 8 to be 9,828,000 net tons, which, while an increase of 885,000 tons over the previous week, which contained a holiday, was 332,000 tons less than the week ended Nov. 24. As in the previous week lack of demand was the dominant factor in limiting production. Preliminary reports indicate a further cut in production last week.

Prices Show Firmer Tendency

Prices were a trifle stiffer last week, *Coal Age* Index showing 181 as of Dec. 17, a gain of one point and a return to the level of Dec. 3. The average price was \$2.19. There were increases in southern Illinois, Mt. Olive, Clearfield, Somerset and Standard districts, with decreases in Kanawha and eastern Kentucky.

There is a little better tone in the Midwest markets due to reduced production, lower temperatures and the nearness of Jan. 1. Domestic coals from Illinois and Indiana move steadier but at low prices. Steam coals in all sections of the Middle West are firmer. The market at St. Louis continues quiet with the movement

of coal depending on weather conditions. Screenings are the feature of the Kentucky markets and prices have advanced.

The Ohio markets felt the effects of more seasonable weather and although wholesale buying did not show any heavy increase, retail dealers were more active. New England reports a better tone, while the Atlantic seaboard market is dull and lifeless.

Hard-coal output fell short of 2,000,000 net tons by about 100,000 tons during the week ended Dec. 8, the Geological Survey estimating the production at 1,899,000 net tons. This was a gain of 151,000 tons over the Thanksgiving Day week, but 201,000 tons less than the week before. A strike last week at some of the large mines will affect the total output. Domestic coals are plentiful and quotations for independent product are easier. Stove and chestnut coals are more plentiful than egg and pea, while the steam coals are hard to move.

The lake season of 1923 virtually closed in the week ended Dec. 9, shipments of soft coal for that week amounting to 109,275 net tons of cargo coal and 7,451 tons of fuel coal. Total shipments of soft coal for the season, according to the Geological Survey, amounted to 31,296,778 net tons, of which 29,678,116 tons was cargo coal and 1,618,662 tons vessel fuel. During the 1922 season total shipments were 19,277,774 net tons; 1921, 23,171,449 tons, and 1920, 23,667,138 tons. Shipments of anthracite for the season amounted to 3,495,582 net tons, which was 153 per cent ahead of 1922, 18 per cent behind 1921, and 13 per cent less than in 1920.

Export shippers are receiving many inquiries but there is not much actual business being booked. Dumpings at Hampton Roads for all accounts during the week ended Dec. 13 amounted to 283,168 net tons, as compared with 308,305 tons the previous week.

Estimates of Production (Net Tons)

(a) Subject to revision. (b) Revised from last report.

More Life in Midwest Now

Low production, cooler days, and the approach of Jan. 1 have combined to give the Midwest coal market a little better tone. Domestic coals produced in Illinois and Indiana are moving more steadily but in very small volume at the present low prices. Southern Illinois prime lump at \$3.75, though unpopular with many dealers who stocked before the recent cut, is barely attractive enough to start movement, and Indiana No. 4 lump at \$3.25 and central Illinois lump at \$2.75@3 show about the same degree of activity. Smokeless mine-run, competitor of these coals, is stiffening up somewhat. The old \$1.40@1.50 smokeless prices have about disappeared; \$1.75 was the average at the end of the week and the trend was upward.

Steam coals everywhere in the Midwest are firmer. Southern Illinois Association producers are trying to reach the \$2 mark with screenings during this week, and were running from \$1.75 to \$1.90 by the end of last. Central Illinois screenings—what there is available after the Standard Oil \$1.25 contracts have been filled—move readily at \$1.50. Indiana steam coals also have improved about 10c. and are

scheduled to go much higher, especially in view of the shut-down of three more big mines and another handful of small ones. There is much inquiry about storage coal to be shipped after Jan. 1. Many buyers are convinced that there is to be a strike, but operators are saying little.

In the Mt. Olive field there are no price changes. A little domestic is moving and screenings are in good demand, but nut and egg are slow. Generally, business in that field is far below what is considered bad. In the Standard field screenings are strong and the small sizes of nut are moving, but domestic is still poor. A little moves, but so little that it is hardly a factor. Cars are plentiful. Railroad tonnage in the Mt. Olive and Standard fields is running light. Mines work from one day in two weeks to as many as four days in rare instances.

St. Louis Idle but Noisy

Business continues quiet in St. Louis. Chilly weather moves a little coal of the cheaper grades in small lots. Demand is light for anthracite, smokeless and coke, and Carterville is slowing up. Retailers who stored heavily on

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

	1923			1922
	Dec. 17	Dec. 10	Dec. 3	Dec. 18
Index	181	180	181	336
Weighted average price	\$2.19	\$2.18	\$2.19	\$4.07

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

Franklin County coals are doomed to take a heavy loss on the Dec. 8 cut in mine price. The feeling generally is not kindly to the operator who makes it possible to buy coal cheaper in midwinter, when screenings are low, than in midsummer, when screenings were high and working time better. Meetings of dealers in St. Louis, Springfield and other places made this a topic for much discussion.

The feature of the week in Kentucky was the advance in the price of screenings, which has mounted to a level starting at \$1 a ton, with some operators refusing anything under \$1.10 and ranging to \$1.35 for nut and slack, the latter grade bringing 15c. or 20c. a ton more than pea and slack. Mine-run and prepared sizes remain unchanged and the advance in screenings is bringing the mine-run average up to a level where the field will reduce its losses materially. Eastern Kentucky screenings are in line with those of western Kentucky, while the latter fields has an advantage of 43c. to 63c. over eastern Kentucky in getting into the Louisville market, and a good movement South, West and North.

Cold weather is finally at hand, with snowfalls reported over the state, and prospects of some business are now apparent. Retailers are getting more inquiries, and placing just a little better volume of business. If the mines that are now down stay down all month, the market will be

much stronger by Jan. 1. Car supply is excellent. The landslide which shut off Hazard field a week ago is now cleared.

Northwest Ready for Strike

The last cargo of coal for the 1923 season arrived at the Head-of-the-Lakes on Dec. 11. Stocks on docks at Dec. 1 were 5,873,000 tons of soft coal and 236,000 tons of hard coal. The soft-coal stocks leave a plentiful supply against any possible shortage by a strike in April. Stocks of anthracite are a disappointment, especially as most of the desirable sizes are missing. Prices are unchanged.

The tendency of the screening market is stronger, this being due to a shortage, which is more feared than manifest at present. The demand for soft coal is light, and it is obvious that the buyers are waiting for a break in the market. The general opinion is that a break will come because of the stocks on hand and the fact that many consumers are well supplied.

At Milwaukee the demand, which fluctuates with weather conditions, is hardly up to what would be expected at this season. Prices remain steady. The last cargo of coal of the season was docked on Dec. 11. The total cargo receipts since the opening of navigation in May aggregated 971,824 tons of anthracite and 3,233,122 tons of soft coal, or 4,204,946 tons in all.

Western Business Spotted

The coming of real winter weather brought more business to Salt Lake City retailers than they have had heretofore this season. They are able, however, to take care of all demands. As a rule the dealers show no desire to stock up for an emergency but are trusting the operating companies to make deliveries as needed. Supplies in local yards are down to about 35,000 tons.

Colorado noted little change in the coal market during the week, the only demand being for domestic sizes. The majority of the operators are still reporting "no market." Prices in the Trinidad district have dropped 50c. so that lump is now \$4@4.50. Labor seems plentiful and the transportation situation is good.

With Southwestern mines working three and four days a week, "no bills" still are accumulating. In the last few weeks there has been a pronounced increase in the surplus of domestic sizes. The surplus of screenings is lessening, but earlier experiences of the year have shown such relief to be only temporary. Operators insist that with screenings at their present price many industries would cut back from oil to coal were it not for the uncertainty of supply.

Lower Temperatures Stimulate Ohio Trade

Slightly colder weather had a stimulating effect on the Ohio coal markets. At Columbus, however, the demand for domestic coals is not active and retail dealers are cleaning up before placing new orders, as they have considerable high-priced coal on hand. Smokeless grades weakened, as well as Ohio-mined coals. Steam trade is slow because of heavy reserves, while purchasing agents are looking for bargains. The Southern Ohio Coal Exchange reports a total output of 131,602 tons during the week ended Dec. 1, with 446 mines reporting, with a full-time capacity of 582,149 tons. "No market" was responsible for a loss of 408,595 tons. Smokeless business at Cincinnati is in a rut as far as prepared sizes are concerned. Reports of mines closing continue to be received in that city and it is said that several operations in Logan County, West Virginia, have announced that they will not turn a wheel from Dec. 20 to Jan. 1. Mild weather has forced the domestic prices down, and consigned and distress coal has been well cleaned up. There has been no change in retail prices.

There has been a demand for slack in the Cleveland market, accompanied by an advance in prices. The only other betterment noted in the situation is a slight improvement in the retail market, due to lower temperatures. Mines in eastern Ohio produced 317,000 tons, or about 45 per cent of capacity, during the week ended Dec. 8.

The Pittsburgh market did not grow any worse last week, nor did it seem to have improved materially. There may, however, have been a slightly heavier demand, chiefly on

account of more domestic distribution. Steel mills are running a trifle lighter, but that is attributed to seasonal conditions, and expect to be operating more heavily next month. Production in the Pittsburgh district is now running at about 60 per cent of rated capacity. Low prices are ruling in nearby non-union regions, presenting more competition for sellers of regular Pittsburgh coal.

Business in central Pennsylvania is dull, although some operators in and about Johnstown think there has been some improvement. Improvement in orders received for immediate shipment has resulted in increased working time.

There was a small stir in demand for slack in and around Buffalo, but it was not of considerable moment. Consumers do not appear to be interested, although colder weather is due.

Better Tone to New England Market

While quotations in New England are as yet little changed there is a rather better tone to the market so far as price is concerned. No. 1 Navy Standard grades can still be had at \$4.35@4.50 per gross ton, f.o.b. vessel at Hampton Roads, but on cars at Providence, Boston and Portland the various distributors are asking more money and in some instances are making sales at \$6 on cars, a level that is 25c. to 50c. higher than a week ago.

Accumulations at Hampton Roads are still large in proportion to current output. Several groups of mines are operating only two or three days weekly but yet there is a surplus far exceeding present requirements. Practically all the rehandling factors are carrying heavy stocks and the agencies at Hampton Roads are at a loss to know where to place January coal. The industries in New England show no substantial improvement, and until there is pronounced strike talk in bituminous for next April it is not probable that there will be any marked increase in demand.

For Pennsylvania coals the prospect is no more inviting than at any time during the last sixty days. Quotations are at a minimum. Bituminous traffic via New York and Philadelphia piers has shown a further shrinkage since Dec. 1, and aside from moderate deliveries on season contracts there is little tonnage moving.

Seaboard Market Dull

There are no signs of an awakening in the soft-coal trade along the Atlantic seaboard. Demand remains quiet and with the exception of a few small orders salesmen report "nothing doing." Receipts at the New York tidewater docks are somewhat heavier while inquiry shows comparatively little improvement. Cars reported at the various docks on Dec. 14 amounted to 1,983, while daily dumpings for the first five days of the week ended Dec. 15 averaged 371. Consumers are "feeling" the market and operators are hopeful of better conditions after Jan. 1. At Philadelphia there are no visible signs of better conditions in the near future. It is believed that the bottom in prices has been reached. Tidewater trade at Philadelphia remains inactive. Bunkering is light and there is little coal at the piers. Conditions at Baltimore have not improved and dealers do not see any immediate change for the better ahead.

Whatever change has taken place in West Virginia has been confined for the most part to slack, which in the southern high-volatile fields ranged during a few days last week

from 90c. to \$1, and in northern West Virginia from \$1.25 to \$1.40, and in some instances as high as \$1.50. The market at Birmingham is slow and sluggish. General demand for spot steam coal is light while the domestic situation is controlled by weather conditions. Production in the Birmingham field for the week ended Dec. 1 was reported as 340,000 net tons.

Independent Anthracite Quotations Lower

Demand for the domestic sizes of anthracite is much easier, especially for independent product, and there has been an accompanying drop in quotations in the New York market. Company coals are going to the retail dealer in larger tonnages and some operators and shippers of independent product have found it necessary to look for orders. Egg and pea coals are the hardest to move, some shippers of the latter size finding it necessary to sell it in conjunction with either stove or chestnut size. Colder weather and a slight snowfall, the first of the present season, created a little better but temporary retail demand both at New York and Philadelphia. Most retail dealers have all sizes for immediate delivery and in New York some retailers have their books well cleaned up and are ready to book new business. The steam coals are moved slowly. Barley is the shortest of the three coals and is in better demand than either buckwheat or rice.

Production of beehive coke during the week ended Dec. 8 is estimated by the Geological Survey to have been 257,000 net tons, a gain of 12,000 tons over the previous week. Output of beehive coke during November was 1,103,000 net tons and of byproduct coke 2,942,000 tons, as compared with 1,290,000 tons and 3,099,000 tons, respectively, during October. Last week the Connellsville coke market failed to develop any additional activity. Spot furnace coke was quotable at \$4, with foundry coke for spot or prompt shipment at \$5@5.50. Two producers of high-grade coke have quotations out for the first quarter, one at \$6.50 and the other at \$6.

Foreign Market And Export News

Improvement in Welsh Coal Market; Output Declines Slightly

Some improvement is noted in the Welsh coal market. Long delayed tonnage is coming to hand freely, and operators and consumers realize that deliveries, owing to the prolonged stormy weather, and the consequent delays of tonnage have fallen behind. The docks are filled with ships and loading operations are proceeding as rapidly as possible.

France is buying well, but with other near-by Continental countries there is no marked activity. Trade with Italy and South America is steady, and a feature of the market is a keen inquiry on the part of buyers seeking to cover fully their requirements to the close of the year. Up to the present Germany's coal credits have not stimulated business in that direction.

The six months trial period of the three shift system at the South Wales ports has expired, but, according to a newspaper dispatch, the tippers have consented to continue at work until Jan. 5, pending further negotiations.

The Newcastle coal market continues to improve. There have been heavy bookings for shipment up to the end of the year and the supply of tonnage has been good.

The report of the loan to Germany to buy steam coals for the railways has been followed by heavy contracts being made all over the country.

Active inquiry from abroad is supplemented by increasing domestic trade demands now that the shipbuilders are resuming work, and the iron and steel operators are extending their operations to meet an expanding trade.

Production of coal by the British mines during the week ended Dec. 1 was 5,719,000 tons, according to a cable to *Coal Age*, a decline of 7,000 tons when compared with the previous week.

Ruhr Industrialists Make Agreement

Announcement has been made in France that agreements with the Ruhr industrialists were made on Nov. 23 to remain effective until April 15 next. They include payment of about 279,000,-

000 fr. as coal tax due from the date of occupation to the time the agreement was made; payment of 10 fr. per ton of coal sold as a tax from Nov. 23; during the period of reorganization of the mines and plants which it is expected will be completed on Jan. 15 next, 18 per cent of the coal produced will be assigned to the Allies as reparation deliveries; free deliveries to begin Jan. 15 next of the monthly supplies prescribed by the Commission for Reparations, in accordance with the peace treaty; free deliveries of by-products; delivery to the Allies of the coal necessary for the needs of the occupation armies as well as for the railroads; acceptance by the German industrialists, according to established regulations, of the control of the mines by Allied engineers; maintenance of export licenses and limitation of exports in the Ruhr.

Export Market Lightens Gloom At Hampton Roads

Business was dull at Hampton Roads last week, with prices showing little change, and with inquiries slackening. Some improvement in export business was shown, although the coastwise trade barely held its own.

The Virginian Ry., partially tied up for several weeks by its engineers' strike, moved slightly more coal, while usually favorable conditions on the Norfolk & Western enabled large volumes of coal to move and to ward off any scarcity of the product.

No outstanding feature was seen in the market. The export cargoes reported were shipped at exceedingly low figures, mainly in an effort to keep coal off demurrage. The tone of the market was dull, and the prospect for the next few weeks was reported as not bright.

Coal Paragraphs from Foreign Lands

Imports of coal into Rio de Janeiro during September amounted to 58,808 metric tons as compared with 85,654 tons during August. Of the total tonnage the United States furnished 7,522 tons and Great Britain 51,286 tons, according to the United States Depart-

ment of Commerce. Imports of coal during the first nine months of this year were 720,314 metric tons, as compared with 689,798 tons in 1922, and 558,344 tons in 1921.

Coal shipments for the season from Spitzbergen were about 400,000 metric tons, according to Consul George Nicolas Ifft, at Bergen, Norway, in his report to the Department of Commerce at Washington. These reports are based on returns from the principal coal companies operating on the island. Shipments are ended for the season.

Export Clearances, Week Ended Dec. 15, 1923

Traffic News

Virginian Ry. Authorized to Extend Guyandot River Branch

The Interstate Commerce Commission on Dec. 14 granted permission to the Virginian Ry. to construct an extension of its Guyandot River branch in Wyoming County, West Virginia, for 1.19 miles to serve new coal mines. This reversed its order of June 25, which denied the road's request.

The construction cost of the extension is estimated by the applicant at \$63,012, of which \$40,812 has been expended for work done in 1917 and 1918. Gross system revenues to be derived from traffic created by the proposed construction are estimated by the applicant at \$226,000 for the first year, increasing to \$1,130,000 for the fifth year. After the first five years the minimum annual revenues are expected to equal those of the fifth year. The increase in net railway operating income is estimated at \$77,309 the first year and \$393,234 the fifth year.

The commission originally denied the application on the ground that the Vir-

ginian had not been able to supply the mines in operation on its lines and that, in addition, there were more mines in the country than was consistent with the most efficient use of equipment.

Application was filed by the railway company for a reopening of the case and the railway was joined in this move by the Pocahontas Fuel Co., Inc., the properties of which were to be served by the proposed extension.

The evidence taken shows that the tractive power of locomotives owned by the Virginian road on Jan. 1, 1922, has been increased 16.4 per cent by the purchase of fifteen Mallet locomotives, which were delivered between July 1 and Sept. 1, 1923. On April 13, 1923, the railway ordered 1,000 steel coal cars of 120 tons' capacity, and 500 of seventy tons' capacity, which will add 30 per cent to its coal car capacity. A contract has been made to electrify part of the lines, and this will add materially to the carrying capacity.

Defer Assigned-Car Order Again

The Interstate Commerce Commission has again postponed the effective date of the assigned-car order, this time from Jan. 1 until Feb. 1.

Suspends New Switching Rate

The Interstate Commerce Commission has ordered suspension until April 3 next of schedules proposed to increase from \$3.60 per car to \$8.10 per car the switching charge of the Wheeling & Lake Erie Ry. on coal and coke received at Toledo, Ohio, from other lines and destined to industries located in Toledo switching limits upon the line of the Wheeling & Lake Erie Ry.

All Freight Records Broken

The railroads of the United States handled 386,027,840,000 net ton-miles of freight traffic during the first ten months of 1923, breaking all past records and an increase of 2.4 per cent over the corresponding period in 1920, when freight traffic amounted to 377,025,000,000 net ton-miles, the previous high record, according to the Bureau of Railway Economics. Compared with the first ten months last year, the total for the same period in 1923 was an increase of 84,495,486,000 net ton-miles, or 28 per cent.

For the month of October this year alone the freight business of the railroads amounted to 42,209,395,000 net ton-miles, which has been exceeded only

in August, 1920, when it amounted to 42,734,000,000, and in October, 1920, when it was 42,570,000,000. Compared with October last year, it was an increase of 2,922,541,000, or more than 7 per cent.

October this year was the eighth month in history when freight traffic on the railroads has exceeded 40,000,000,000 net ton-miles. This mark was attained once in 1918, again in 1919, and four times in 1920. It was not reached in 1921 or 1922, but so far has been reached twice in 1923.

Dates Set for Lignite Hearing

The Interstate Commerce Commission on Dec. 14 set dates for hearings of the protest filed against proposed increases on lignite rates out of North Dakota. The first hearing will be held at Aberdeen, S. D., on Jan. 7, and a second at Bismarck, N. D., on Jan. 10. Governor Nestos of North Dakota recently urged President Coolidge to assist coal interests in that state in resisting the increase, whereupon the new rate schedules were promptly suspended.

New Connection for Ohio Mines

The struggles of a number of small operators near Dover, Tuscarawas County, Ohio, for railroad connections which would enable them to market their product, started a year ago have been crowned with success. The Ohio Utilities Commission has ordered the

Pennsylvania R.R. to make the necessary connections. The case was carried to the Supreme Court by the railroad company but that tribunal upheld the order of the Ohio Utilities Commission.

Would Build Alabama Line

The Muscle Shoals, Birmingham & Pensacola Ry. has applied to the Alabama Public Service Commission for a certificate of convenience and necessity for the construction of a railroad from Kimbrough, the present northern terminus of the line, to Jasper, Ala. It is contended that the new line will shorten the distance between central points and the gulf and will also open coal and ore fields and timber tracts in North Alabama not now served by any railroad.

Ford Seeks 43-Mile Cut-Off

The Detroit, Toledo & Ironton R.R., Henry Ford's road, asked the Interstate Commerce Commission Dec. 15 to authorize a new forty-three-mile line between Wauseon, Ohio, and Durban, Mich., for which permission was sought to issue sufficient mortgage securities for financing. The chief purpose is to reduce distances of the Ironton road into Detroit. According to the map filed with the commission, the cut-off would be absolutely straight for the entire forty-three miles.

Pennsylvania to Improve Docks

The Pennsylvania R.R. will expend \$500,000 in the improvement of its dock facilities at Erie, Pa., according to advice received in New York Dec. 13.

Coal Legislation Hopper

Two bills for the creation of a Department of Mines, with a Secretary and Assistant Secretary at its head, have been introduced in the Senate. One is by Senator Oddie, of Nevada, chairman of the Senate Committee on Mines and Mining, and the other is by Senator Shortridge, of California, and differs slightly from Senator Oddie's bill. Both measures have been referred to Senator Oddie's committee.

Representative Bacharach, of New Jersey, has introduced in the House a bill to improve the navigability of waters of the United States by preventing their pollution by oil.

Representative Davis, of Minnesota, has presented a bill proposing the establishment of an International Exposition of the United States of America, in the interest of mining, agriculture, labor, etc.

Representative Vinson, Georgia, has introduced a bill to amend the Interstate Commerce Act so that it would be unlawful for any rates, fares or charges to exceed those in effect on Feb. 28, 1920; also that "Nothing in the Transportation Act, 1920" shall diminish or extinguish the jurisdiction of any state or any agency thereof, of any common carrier or railroad, or the rates, fares, charges, classifications, regulations, or practices of any such carrier or railroad.

Representative Hawes, Missouri, has introduced a bill similar to one introduced by him in the last Congress, intending to create seven regional committees to consist of three members each, located in seven regions, practically similar to the regions in existence during governmental operation of the railroads. The Interstate Commerce Commission would remain at Washington under this bill as a sort of a Supreme Court of Commerce.

News Items From Field and Trade

ALABAMA

Recent incorporations in Jefferson County include the **Neill Coal Co.**, with a capital of \$20,000, of which \$8,000 is paid in, and of which John C., Ab. and H. C. Neill are the organizers.

The **Hilliard Coal Co.** is arranging to reopen its **Hilliard mine**, west of Jasper on the Frisco R.R., which has been idle for some time. The mine was developed some time ago at considerable expense and is owned by James Ensor, Brady Earnest and Manly Johnston, of Cordova, and T. B. Dilworth, of Jasper.

The **Pratt-Warrior Coal Co.**, of Jasper, is making arrangements to erect twenty-five new tenement houses for employees at their Ivy Bluff Mines, in Walker County. The mines were recently leased to the Gulf States Portland Cement Co., of Demopolis, which is now operating them and taking the entire output. Motor haulage was recently installed in the mine and the new houses will enable the company to obtain additional employees for the increased output needed. The mines are located on the Warrior River, on which stream the plant of the cement company also is situated, and all coal is moved by barges to destination.

ILLINOIS

The **Middle Fork Mine**, one of the best and largest collieries near Benton, owned by the **United States Fuel Co.**, has been closed down, throwing approximately 800 men out of work. The shutdown was brought about by a refusal of the "drivers" to take a small reduction in their daily wage, the company deciding it can buy coal cheaper than it can mine it under the present conditions, as the **Standard Oil Co.** decided at its two Illinois mines, now down. The output of the **Middle Fork mine** was used at steel plants operated by the company at Joliet.

Both shafts of the new **Nason mine** at Nason are now in coal. "B" shaft reached it Dec. 4 at 735 ft. About 150 ft. of main entry was driven in the first two weeks after the first shaft was finished. Development is going on day and night. "B" shaft, which measures 12 ft. 6 in. by 32 ft. 6 in., is one of the largest in the country and upward of 1,000 tons may be the daily tonnage by April 1. By Jan. 1, 1925, mine experts think this mine will break all records for quick development with a 5,000-ton daily output.

No direct responsibility has been placed yet for the flooding of the **Radium mine** at Belleville on Dec. 6. The report shows that the operators of the **Chester mine**, abandoned some 25 years ago, failed to chart its workings correctly. The survey of the coal leases held by the **Radium mine** indicated that there remained at least 500 ft. of coal between its nearest working face and the old mine. Evidence is reported to the effect that coal was taken long ago from leases not reported by the **Chester mine**. At present the pumping is equal to the rising water in the **Radium shaft**. The three bodies were recovered the day following the flood. New pumps are being installed that are expected to pump out both mines in two weeks' time and work will be resumed when an examination of the old mine is made to guard against a repetition of the accidental breakthrough.

Roscoe B. Starek has left the **Binkley Coal Co.** to become vice-president in charge of sales for the **Leland Coal Co.** of Chicago, a company which now holds Illinois, Indiana and Kentucky properties. H. A. Stark, long with the **Bogle Coal Co.** before L. G. Binkley acquired the **Bogle properties** in Indiana, now succeeds Mr. Starek as vice-president in charge of sales for the **Binkley Coal Co.**

The **Quaker Mining Co.**, 37 West Van Buren Street, Chicago, has been incorporated by H. A. Huskey, George G. Haase and R. L. VanHoose.

A loss of \$200,000 was suffered by the **Taylor Coal Co.** in its Dec. 1 fire, which destroyed the recently rebuilt washery and wooden tippie at Herrin.

M. F. Peltier, vice-president of the **Peabody Coal Co.**, Chicago, returning from a trip of inspection among the **Sheridan Coal Co.** mines in Wyoming, said conditions in the coal industry in the West have seldom been less auspicious than they are now.

The appointment of a receiver for the **Kolb Coal Co.**, of St. Louis, which was made on Oct. 16, was vacated ten days later by the Circuit Court of Appeals, at Chicago, which also ordered that the operation of the order for the appointment of the receiver and all proceedings thereunder should be stayed pending the hearing and determination of the appeal and that all property of the **Kolb Coal Co.** should be returned to it. The appointment of the receiver was made on the application of P. H. Sauter to the U. S. Court for the Eastern District of Illinois, against the coal company and others, the bill alleging that there was a dispute between the plaintiff and certain of the defendants relative to the ownership of 1,200 shares of the capital stock of the company. There were no allegations in the bill that in any way reflect upon the **Kolb Coal Co.** or its solvency or financial condition, and no relief of any kind or nature is sought against it.

The **Kathleen mine**, at Dowell, operated by the **Union Colliery Co.**, of St. Louis, smashed its own hoisting record twice in a week, hoisting a total of 5,232 tons the second day and 4,902 the first day. The first record was made Dec. 12 and the second on the 14th. The mine has been in operation about four years and is expected to produce around 6,000 tons daily after development work has been fully extended. I. N. Bayless, of Dowell, is superintendent of the plant, and John Hays is mine manager.

IOWA

The **C. M. & St. P. R.R.** is building a double track spur one mile from its main line at Madrid, to the new mine of the **Madrid Coal Co.**, which previously has been only a wagon operation.

Prof. S. W. Parr, of the University of Illinois, in an address before the Illinois and Iowa members of the American Chemical Society recently, enthused Iowa operators by promising that Iowa would become one of the great fuel-producing states of the country in the next fifteen to twenty years. He described low temperature carbonization, the best process by which the poor grade of coal that lies under twenty-three Iowa counties can be converted into high-grade coke—"the most desirable fuel in the world today"—and declared there is a great future for this process.

KENTUCKY

Harlan reports that the **United Mine Workers** have established an office in that town, and are working hard in an effort to unionize the southeastern Kentucky field, a drive having been under way in the Pineville district for some time, with recent discussion of moving district offices from Knoxville, Tenn., to Pineville.

W. B. Gathright, general manager of the Louisville wholesale and retail departments of the **St. Bernard Mining Co.** of Earlinton, has resigned effective Jan. 1, after being with the company since he was a boy.

It is reported that additional mines in the **Harlan and Middleboro districts** have cut wages during the past few days. Mines on **Clover Fork** are said to have been the first to cut, and reductions have been quite general of late as a result of many mines being down, hundreds of men out of work and others willing to accept cuts if it will keep them on the payroll.

An interesting Geological Survey report from Washington on Dec. 10, showed that machine-mined coal in Kentucky ran much larger than most coal men believed, the report showing 71 per cent, or 33,322,271 tons, machine cut out of 42,134,175 tons mined in 1922. A total of 5,355,037 tons, or 12.7 per cent, was shot off the solid, and 4.2 per cent, or 1,766,963 tons, was hand mined.

Stripper operations in western Kentucky produced 468,845 tons, or 1.1 per cent, and 1,221,059 tons or 2.9 per cent carried no specification as to how it was mined.

The **City of Henderson** is now enjoying the cheapest coal in Kentucky. Last week a local mine reduced prices on lump from 18 to 16c.; nut from 18 to 15c. and slack from 10 to 8c., delivered. Prices are 3c. lower at the mine. The quotations are the lowest since 1916.

Illustrating the coal-mining activity recently in **Muhlenberg County**, Inspector M. H. Blythe's report shows that the **Beech Creek Coal Co.**, of Drakesboro, opened a new mine, **Beech Creek No. 3 $\frac{1}{2}$** , on the Louisville & Nashville last March. During September one mine shut down permanently because it was worked out—**Williams No. 9**, of the **Beaver Dam Coal Co.**, of **Beaver Dam**—and in November four mines opened up. These were the **Morrison** and **Curshaw strip properties** of the **Morrison Coal Co.** and the **Curshaw Coal Co.**, both of **Centertown**, and two mines belonging to the **Beaver Dam Coal Co.**—**Sackett No. 9** and **Black Cat No. 11**, both at **Beaver Dam**. In that one county three strip mines opened during the summer and autumn. These were the **Harris strip mine** of the **Harris Coal Corporation** of **Island**, which began shipping on the **L. & N.** in June, and the two strippers mentioned earlier in this paragraph.

MISSOURI

Announcement has been made of the sale of stock in the **Central Coal & Coke Co.** owned by C. F. Fox, investment banker of Philadelphia, to a syndicate composed of Charles S. Keith, Kansas City, president of the company; Henry F. Hall, Kansas City, a director, and John Henry Kirby, of Houston, Texas. Mr. Kirby bought the greater portion of the stock sold. This consisted of the entire Fox holdings in the company, 11,675 shares. The price paid was \$126 a share, or \$1,471,050 cash for the entire transaction. "The deal gives the purchasers undisputed control of the company," Mr. Keith said. "Mr. Kirby bought the largest portion of the Fox interests. About 50,000 of the 70,000 shares of stock in the **Central Coal & Coke Co.** are now owned by Western men. There will be no radical change in policy. Mr. Kirby will take the place of Mr. Fox on the board of directors. The officers will remain the same." This is considered to dispose of the story that Eastern interests controlling the U. S. Distributing Corporation were to buy control of this coal company.

NEW YORK

The **Mahoning Railroad Co.**, on Dec. 11 declared a dividend of \$10 a share on its common stock, payable Dec. 28 to stockholders of record Dec. 21. Dividends of \$10 a share were also paid in October, June and April of this year. In addition, the directors declared the regular semi-annual dividend of \$2 a share. The regular quarterly dividend of \$1.50 a share was also declared on the preferred stock.

A special meeting of stockholders of the **Consolidation Coal Co.** has been called for tomorrow to vote on a proposed amendment to its charter permitting a change in the par value of its capital stock and the issuance of \$10,000,000 7 per cent cumulative, redeemable preferred stock, from the sale of which it is planned to reimburse the treasury of the company for capital expenditures in the acquisition of properties and to provide new working capital.

Directors of the **Island Creek Coal Co.**, on Dec. 11 declared an extra dividend of \$1 a share on the common stock of the company and the regular quarterly dividend of \$2. The regular dividend of \$1.50 a share was declared on the preferred. All dividends are payable Jan. 2 to stock of record Dec. 21.

Governor Smith on Dec. 11 appointed a fair price coal commission for **Poughkeepsie**, as follows: Clinton H. Laurence, representing the coal dealers; Otis Sherman, for the general public, and William T. Ward.

Emerson E. Davis of **Saratoga Springs**, has been appointed by Governor Smith as the third member of a fair-price coal commission for that city to serve with William E. Benton and Eugene E. Hayden, appointed by Acting Mayor Sherman. Mr. Benton is manager of a theater and Mr. Hayden is secretary of the **Saratoga Coal Co.**, representing, respectively, the consumers and the coal dealers. Mr. Davis will represent the state.

OHIO

A new trial of the Hopper-Mankin Fuel Co. against the Matthew Addy Coal Co. has been asked in the U. S. District Court. The Hopper-Mankin company was denied judgment for \$81,000 for coal delivered to the Matthew Addy Steamship Co., Judge Hickenlooper instructing the jury that the Matthew Addy company could not be sued for a debt contracted by the steamship company.

All bids, which were received by E. L. McCune, clerk of the Columbus Board of Education, Nov. 8, for furnishing and delivering 1,000 tons of Hocking nut, pea and slack to the site of the New Central High School, were rejected at a recent meeting and will be readvertised. The date as yet has not been set. The following were low bidders: Euga & Stinchcomb, \$2.91; Reliable Coal & Supply Co., \$2.98, and the J. C. McIntyre Coal Co., \$3 per ton delivered.

OKLAHOMA

The International Fuel Corporation has taken over the Champion mine at Louisville, formerly operated by the Republic Fuel Co. This mine is not running at full capacity, but the operating company hopes to have a good output within the next few weeks.

A close examination of the coal deposits near Oklahoma City will be made by experts in the near future. It is believed that the examination will prove the existence of extensive deposits of high-grade coal. Coal was mined in the Fourteen Mile Creek locality many years ago and more recently work has been done by persons who leased a portion of land from Indian citizens. An attempt will be made to interest wealthy operators in the mining of the coal, in case a large deposit is found.

PENNSYLVANIA

Delegates representing the United Mine Workers of District No. 2, which includes practically all of central Pennsylvania, will go to the International convention in Indianapolis, Ind., on Jan. 17, standing behind two demands as to the next scale contract. The first is for a six-hour workday and the second is for a 20 per cent increase in wages.

By agreement of counsel at Sunbury on Dec. 4 the Lehigh Valley Coal Co., and the Susquehanna Collieries Co., in their appeal from assessments on anthracite lands in Northumberland County, which has been pending more than a year, it is announced that the former will pay taxes on an increased valuation of 40 per cent on approximately \$15,000,000 worth of coal land; the Susquehanna on \$11,000,000 worth. These appeals had been in the hands of the court for adjudication. The Philadelphia & Reading Coal & Iron Co. has already agreed to a 40 per cent rise in taxable valuation on \$26,000,000.

Shipments of anthracite for the month of November, 1923, as reported to the Anthracite Bureau of Information, Philadelphia amounted to 5,828,754 gross tons, as compared with 6,564,526 gross tons during the preceding month, a decrease of 735,772 tons, or 11 per cent. This decrease can be attributed to holidays observed during the month. The average daily shipment for the time the collieries were in operation during the month of November exceeded that for the month of October. Comparing November shipments of this year with the corresponding month in 1921, the latest normal year, an increase of 514,740 tons is shown, or 9.7 per cent. Shipments by originating carriers were as follows:

	November 1923	October 1923
Phila. & Reading....	1,038,340	1,205,425
Lehigh Valley	1,006,983	1,174,768
Jersey Central.....	493,915	564,471
Del., Lack. & Western	937,222	1,017,231
Delaware & Hudson...	820,301	861,705
Pennsylvania	509,457	576,345
Erie	623,101	707,076
N. Y., Ont. & Western	153,075	174,707

The fire which recently damaged the plant of the Phillips Mine & Mill Supply Co., Pittsburgh, was confined to one portion of the buildings and was not as serious as at first reported. The company announces that within a week or ten days it will be able to handle all business with its usual expedition and dispatch.

WEST VIRGINIA

Further trials of those who participated in the armed march against Logan in 1921 will be held in Fayette County, Monday, Feb. 11. There was a change of venue from Greenbrier to Fayette County in November. The first defendant to be placed on trial will be William Blizzard, president of sub-district 2, of District 17, who is charged with being an accessory to murder. C. F. Keeney, president of the district, and Fred Mooney, secretary of the district, also are under indictment. The cases will be tried before Judge Early and it is expected that 250 witnesses will be in attendance, about 200 of whom will appear for the defense. Officials of the miners' union will be represented by H. W. Houston and T. C. Townsend, of Charleston. The state will be assisted in the presentation of its case by George Love, prosecuting attorney of Fayette County, and by C. W. Ossenton. Fayette will make the fourth county in West Virginia in which trials of some of the armed marchers have been held. The first trials were held in Jefferson. Then there was a change of venue to Morgan, then to Greenbrier and finally to Fayette.

Announcement has been made that the Wheeling Steel Corporation is negotiating for 10,300 acres of coal land in Mason County, extending from New Haven to Letart, on the Ohio River.

The Ideal Manufacturing Co., has just been organized by Charleston capitalists, and will establish a plant in Charleston. The company has been chartered with a capital stock of \$5,000 for the purpose of manufacturing mining machines. Incorporators of the new company are John G. Bulmer, of Lory; James W. Smiley, S. L. Walker, A. S. Jenkins and R. Stewart, all of Charleston.

The Kelly's Creek Colliery Co., one of the large concerns operating in the Kanawha District, the main office of which is at Cleveland, has been granted authority to increase its capital stock from \$1,900,000 to \$2,000,000. The Paisleys, of Cleveland, are largely interested in this company.

Plans have been perfected for the erection in Huntington of the Coal Exchange Building, to cost approximately \$1,000,000. It will contain 325 office rooms where many of the coal companies of the tri-state region will have headquarters, applications for space in the new building having been made even before construction work had been started. The building is to be thoroughly fireproof and is to be built of steel, terracotta, stone, concrete and brick. The Huntington Coal Exchange began to plan for the building about the time the coal exchange was organized.

WASHINGTON, D. C.

The new Senate Committee on Mines and Mining is composed of the following: Republicans—Oddie, Nevada, Chairman; Elkins, West Virginia, Phipps, Colorado, Cameron, Arizona, and Frazier, North Dakota; Democrats—Walsh, Montana, Ashurst, Arizona, Pittman, Nevada, and King, Utah. Senators Norbeck, South Dakota and Couzens, Michigan, Republicans, former members, were not retained, and all of the Republicans except Senator Oddie are new on the committee. Senator King is a new Democratic member on the committee.

Senator Borah, Republican, Idaho, is chairman of the Senate Labor Committee, new members of which are Brookhart, Iowa, and Dale, Vermont, Republicans; and Ferris, Michigan, and Copeland, New York, Democrats. Senators dropped from this committee are Warren, Wyoming; Shortridge, California; Republicans; and McKellar, Tennessee, Democrat.

The U. S. Supreme Court on Dec. 3 reaffirmed the decision it handed down in June declaring unconstitutional the West Virginia law which would compel natural-gas companies piping gas from that state to supply needs within the state before sending gas into other states in periods of shortage. The vote of the court was five to three, one justice not participating, as was the case in the original decision. In its original decision the court declared that natural gas which has been piped into other states assumes the character of interstate commerce. A rehearing was granted West Virginia. The latest opinion merely recites that nothing was presented to change the first opinion of the court. The decision was on consolidated suits brought by Pennsylvania and Ohio against West Virginia.

President Coolidge has sent to the Senate the names of Mark W. Potter, of New York, and Frank McManamy, of the District of

Columbia, as members of the Interstate Commerce Commission for seven-year terms beginning Jan. 1 next.

CANADA

William and George Hastings, members of the coal firm of Hastings & Sons, Woodstock, Ont., were fined \$25 and costs each at an adjourned sitting of the police court for having sold as coming from Alberta coal mined in the United States. The difference in the price was refunded by the company to those who had purchased the coal.

If Canada consumed coal from Alberta instead of going outside the Dominion for it, 60,000 jobs at \$1,500 per annum each would be maintained, according to Commissioner Howard Stuchbury. "We are paying out each year the equivalent of \$300,000,000, or the equal of the national debt in eight years," he said. "The West cannot pay its debts to Ontario because it has no money and, therefore, cannot buy Eastern products. But it has the coal wherewith to pay. Premier Ferguson stated recently that we are going to get a rate on Alberta coal before we are through."

Association Activities

The Northern West Virginia Coal Operators Association has filed with the Interstate Commerce Commission a brief urging adherence to its original decision in the assigned-car case. It is declared in the brief that the decision of last June is sound and logical inasmuch as it assures equality of treatment to all shippers regardless of size and power. It is pointed out that mines having cars assigned to them are afforded a full supply, reduce the cost of production at such mines, but cause an increase in the cost of production at other mines. The Association, through its executive vice president, George S. Brackett, also is actively opposing any change in the rates through the Potomac Yards, near Washington, in conjunction with the Upper Potomac Association.

The annual meeting of the Winding Gulf Operators Association held at White Sulphur Springs, W. Va., on Dec. 12, was featured by an address by H. L. Gandy, executive vice president of the National Coal Association. E. E. White, president of the E. E. White Coal Co., of Glen White, was chosen as president of the association for the fifteenth consecutive year. Other officers chosen were: P. M. Snyder, Mt. Hope, W. Va., vice president; George Wolfe, of Beckley, W. Va., secretary; A. W. Laing, of MacAlpin, W. Va., treasurer; members of executive committee, E. E. White, P. M. Snyder, A. W. Laing, W. G. Caperton, of Slab Fork; C. H. Mead, of Beckley, W. Va.; George R. Collins, of Charleston; Fred G. Wood, of Amigo, W. Va.; W. B. Beale, of Fireco, W. Va.; F. W. Lee, of Alpoca, W. Va.; W. H. Ruby, of Whitby, W. Va., and T. H. Wickham, of Beckley. Mr. Gandy reviewed the present coal situation and the prospect of legislation affecting the industry. He expressed himself as strongly opposed to any organization which attempted to set itself above the law. In calling attention to the present oversupply of coal, he stressed the necessity of being in a position to produce the peak load. The association endorsed the efforts to obtain such rates that would permit the movement of smokeless to Eastern states by rail.

Coming Meetings

Tug River Coal Operators' Association. Annual meeting Jan. 4, 1924, Bluefield, W. Va. Secretary, C. C. Morfit, Welch, W. Va.

New England Wholesale Coal Association. Annual meeting Jan. 8, 1924, Boston, Mass. Secretary, R. S. Townsend, Boston, Mass.

Engineers' Society of Western Pennsylvania. Annual meeting Jan. 15, 1924, Blue Room, William Penn Hotel, Pittsburgh, Pa. Secretary, K. F. Treschow, Pittsburgh, Pa.

American Wood Preservers' Association. Annual meeting Jan. 15-17, 1924, Hotel Buehlebach, Kansas City, Mo. Secretary, P. R. Hicks, Chicago, Ill.

Northeast Kentucky Coal Association. Annual meeting Jan. 24, 1924, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

New Equipment

Automatic Mine-Car Coupler

The introduction and use of heavy all-steel mine cars of four tons or more capacity together with corresponding increase in size of all other equipment, such as rotary dumps, hoists, haulage locomotives, etc., has been effected with a view toward efficient high-speed production and low cost per ton.

During this period of development considerable time and study have been given to almost every detail connected with the production of coal, many machines having been perfected to operate with complete automaticity. The Ohio Brass Co. has, therefore, developed the Tomlinson automatic coupler for use on mine cars. This coupler has been applied to steam and electric railways for many years.

The coupler is completely self-contained, having no loose parts to become mislaid or lost. It is always ready for coupling either on straight track or curves, thus eliminating the necessity of anyone stepping between the cars

CAR WITH AUTOMATIC COUPLER

to adjust any part of the coupler. Heavy steel draft gear relieves the car body from abuse and shocks, thus prolonging the life of the equipment. A ball and socket type of anchorage permits operation of the car on a rotary dump, and ready means for uncoupling and transposing from a coupler to a bumper makes it suitable for hoisting operation.

Safe Blasting-Cap Container

Built like the cartridge chamber of a six-shooter, the new du Pont blasting cap container, illustrated here, is the most recent blasting accessory offered by the duPont Company. It meets a real need of blasters who, for lack of a service container, have heretofore carried detonators loosely in their pockets or in the tin boxes in which they are sold. This practice has frequently resulted in serious and sometimes fatal injuries. By the use of this new device the likelihood of such accidents will be greatly minimized.

The body of the container is made of vulcanized rubber. Drilled at regular intervals into its thick side walls are ten holes, each large enough to

CONTAINER FOR BLASTING CAPS

accommodate a blasting cap. The polished brass top cannot be removed, but can be rotated around the rivet pin which firmly secures it, so that the vent exposes the ten compartments one at a time. You fill the container with blasting caps just as you would load a six-shooter with cartridges. After filling, the top can be turned so that the vent is effectually closed over a blind hole. Incidentally, this top is designed to prevent accidental turning.

The legend—"Blasting Caps—Dangerous—Handle Carefully"—is embossed in white letters on the back of the container along with the following safety rules:

Do not remove caps with wire or nail.

Don't tap or otherwise investigate them.

Don't carry caps loose in pocket.
Don't store in residence.
Don't smoke near caps.
Don't shoot into caps.
Attach caps to fuse with cap crimper, not with knife or teeth.
Keep in a dry place.
Keep open lights away.
Containers are made for No. 6 caps and for No. 8 caps.

Screen That Both Shakes And Vibrates

Two types of a screen that both shakes and vibrates are made for either coarse or fine screening by the Southwestern Engineering Co., Los Angeles, Calif. It is used both for wet and dry material. When the material is dry and fine the screen may be enclosed so as to prevent dust from flying in the air and lighting on the sills, ledges and floor of the tippie or other building and air suction may be applied to draw away the finest particles.

This screen, which is known as the Cottrell, consists essentially of a screen frame or frames, rapidly vibrated by the rotation of an unbalanced pulley. Excessive speeds have not been found necessary, 400 to 1,000 r.p.m. being sufficient for practically every screening condition, according to the manufacturers. The screen cloth is said to last longer than in most types of screens because it is not put under great tension, for both the screen frame and the screen cloth are vibrated. For rough work, perforated metal screens may be used in place of screen cloth.

One, two or three screen decks may be used. The screen in type A can be set at angles from 10 to 30 deg. from the horizontal and it will therefore move at an angle to the screen frame. In type B, which may be used for any material coarser than 20-mesh and is run at 200 to 400 r.p.m., the screen has a motion at right angles to the screen surface. This bumping movement is ordinarily between one hundredth of an inch and 1½ in.

NEW YORK, DECEMBER 27, 1923

Number 26

Presidential Years

WHAT are we to infer from the recent broadsides proclaiming and proving that the generally accepted conviction that a presidential year means poor business is both false and foolish? L. P. Ayers, vice-president of the Cleveland Trust Co., a statistician of national reputation, and Congressman Martin L. Davey have separately and independently hit that old theory a bump. We have never had a shred of belief in the theory that presidential years made or unmade business or that changes in administration have a tangible influence on the business cycle. It is good to have it proved, however. Perhaps when we have more businessmen with trained minds mixing in the political game there will be less resort to such old adages that one party or the other brings prosperity just because a good crop in a presidential year following a poor crop may re-elect the party in power.

Since 1880, it seems, there have been five lean presidential years and five fat ones. Colonel Ayers' indexes show the presidential year has an even break as between above and below normal. Now there is much talk these days about the influence of the coming presidential year on a new coal-wage contract for next April. Just what influence can it have?

In the first place the influence, if any, must be pronounced and exerted in advance, because the negotiations open in January to renew a contract that expires with the end of March. At that time the political aspects of 1924 will still be in flux. Conventions are months away, policies in the making, Congress a Roman arena for bloc fights. Now it is granted that the powers that be, and perhaps as well those that hope to be, would be in a sorry plight were they to be obliged to stage a presidential campaign under such stress as the coal strike produced in the summer of 1922. One can well imagine that the administration would gladly have such a contest postponed. The memory of the ineffectiveness of Washington in the 1922 conflict is altogether too fresh to invite a repetition.

What brings about a strike? Is political influence any more likely to avoid or postpone such an event than to bring prosperity or decree depression, raise a bumper crop or introduce plague or drought? Hardly. An overheated imagination might picture some power behind whispering to the coal operators that there must be nothing to ruffle the calm sea of 1924 prosperity, and directing that they go forth and give the union miners whatsoever they may demand, but coal operators don't throw their business away after that fashion. No one supposes either that the United Mine Workers will listen to advice from Washington in 1924 any more than in 1922. Their course of action, like all organized labor's course in the country, is not dependent on party politics. The miners will strike or refrain from striking at the dictation of no political group.

No, the government or the party cannot by edict or

by pressure control this situation. Whatever influence the fact of a presidential year may have on labor relations in soft coal will flow from the natural conservatism of individuals who would shrink from stirring up more trouble than is already in prospect. The greatest hope for peace in coal in 1924 lies in the very evident desire of both parties to avoid a dispute, and in no wise is to be attributed to the magic influence of a presidential year.

Business Statistics

HOW much of the stability that has characterized business this year is to be attributed to sounder knowledge of the course of industry cannot be ascertained with precision. The better knowledge afforded by the regular collection of trade information by the Department of Commerce and published through the Survey of Current Business has met with the hearty approval of industry. The steady drive for continuous operation, the mitigation of unemployment and the softening of alternate booms and slumps, in which Herbert Hoover has been the outstanding leader, is bearing fruit. Beyond doubt what Mr. Hoover did in 1923 is more largely responsible for the even tenor of soft-coal production this year than any other factor.

It must be remembered that all the results so far obtained have been from statistics voluntarily supplied. The trade associations have been encouraged to co-operate with the government. In view of the decree recently entered in the Tile Manufacturers case by which the field of these voluntary trade reports is greatly restricted, if not indeed reduced to the request of some government department, there is raised the larger question as to whether the policy of the Department of Justice is not directed toward the total extinguishment of trade-association effort. Some would devise a method of forcing a showdown between the policies of the departments of Justice and Commerce, but there is the fear that if the question of legality were raised there would inevitably follow a period of uncertainty that would be sure to wreck what even now is left and thus remove the few props that business has.

The coal industry, save for the incomplete co-operation now afforded the Geological Survey, is at a standstill in the statistical field. Groups here and there are seeking a way of increasing the effort on a voluntary basis. The sentiment in favor of making all participate is strengthened by the knowledge that altogether too many coal men are seemingly opposed to any form of publicity of accounts. From a purely selfish business standpoint the coal industry, particularly the soft-coal industry, needs more current information as to its general condition. If it is not willing to undertake voluntary even though incomplete reporting, it must always face attempts to compel the collection of these data.

It is agreed that there is little or no legal ground on which the government can compel such reports, but it must not be forgotten that time can remedy that remissness in the law.

A Lesson in Power-Plant Design

THERE are two aspects to the subject of power generation of vital interest to coal men: The cost of power to them as consumers, and the decreased demand for coal as efficiency in its use mounts. The direction of movement today is toward utilization at mine power plants of what otherwise would be waste and the demand from distant power plants for the higher grade fuel.

The power-plant engineer who visited the recent Power Show held in New York has gone back to his work with a new vision of the future. The time once was when the power plant was laid out and erected with no thought of the efficiency with which the plant was to operate. This was a question which was supposed to depend more upon the ideas of the operating organization than the equipment put into the plant. Power plants were built and experimentation carried on afterward. Today every detail of the plant and its operation is figured out first and every item and piece of equipment must fit into the plan for most efficient operation. Long before the plant produces power close approximate operating data are available.

The most uninitiated engineer could not help but be impressed with two important facts as he viewed the Power Show exhibits. The first is that the generation of power is developing into a highly specialized industry with hundreds and thousands of pieces of apparatus designed to obtain the highest degree of efficiency in the handling and burning of all kinds of fuel. The second important fact is the rapid stride made in the utilization of the small sizes of coal. Stokers, pulverizers, furnaces, boilers all are being adapted and perfected for the utilization of what we have always considered waste. With the perfection of this equipment and advancement in control and metering accessories we are seeing the power plant revolutionized. Power plants now ten years old are obsolete and must go to the scrap heap unless revamped.

Keep an Eagle Eye on Mine Supplies

THERE is a more or less exact level at which every coal mine's stock of supplies should be maintained. Keeping it there is more of an art than many a veteran mining official may imagine. And because he does not imagine it he also probably never thinks of computing the cost of carrying too much stock—or too little. Yet all the while his company may be paying heavily for this omission.

The generous habit of buying a gross of brake shoes at a time, even though it takes a year to use that many, simply means that a certain number of dollars that might be working elsewhere for a mine company are kept "frozen" in brake shoes. This loss might be greater than the discount obtained by quantity buying. Who knows, if nobody in the company takes the trouble to figure out after a time study of brake-shoe consumption by that particular company?

On the other hand, penurious buying, aimed to prevent the loss of capital working value, might reduce the stock of brake shoes too low. This would not only deprive

the company of the quantity-purchase discount but also might easily cause the tie-up of equipment waiting for shoes. Here again a loss would ensue, so that the total loss would be greater than that caused by overstocking. This situation is applicable to almost any line of supplies in the whole stock at a mine. The subject is worthy of closest study, especially by those operators who have never delegated a good man to make a careful survey of the problem as it applies to each particular property.

One authority says the cost of carrying excess and obsolete stock in this country amounts to as much as 3 per cent a month, which means \$360 a year on every \$1,000 invested in stock! Mr. Hutchings, in his article in this issue, points to this astonishing expert opinion and urges mining men to watch their stock turnover, to protect the supplies on hand from depreciation, and to find out what their excess stock losses are. It is sound counsel.

West Virginia and New York

AN ATTRACTIVE little booklet, excellent propaganda, favorable and unfavorable, truthful yet not recriminative, broad minded and convincing, has been written by Phil M. Conley, managing director of the American Constitutional Association, Charleston, W. Va., an organization on which serves Governor E. F. Morgan and I. C. White, the well known geologist of Morgantown, W. Va., and several representative citizens of West Virginia towns. The book is entitled "Life in a West Virginia Coal Field," and it studies conditions in fifty-eight Kanawha and Coal River villages.

Reading it, one feels disposed to wonder if the people of New York do not need some counter propaganda to spread about the valleys of the Kanawha and Coal River. So much has been written about its bandits, its robberies, murders and arson, its night life, tango lizards and giddy whirl of fashion, its mayors and aldermen, the high death rate on the city streets, the squalor of its tenements, its cold-blooded capitalists and its bucket shops, its missing children, its loveless homes and its divorces, its illicit bars and its dope fiends, its crowded schools and its not-too-clean politics, that it also needs a vindicator.

It surely needs to convince the inhabitants from Charleston to Thurmond and to Raleigh and beyond that the people of New York really are home-loving, industrious and dependable, with self-respecting homes, a happy, kindly even religious folk, the kind of men and women whom to know is to like, whom to meet is to trust. They need to undo the work of the moving-picture houses and the press, which takes almost pornographic delight in ferreting out evil rather than virtue.

We propose therefore that the American Constitutional Association survey New York also and deliver for the denizens of that city that same unvarnished tale that they have written of the coal fields contiguous to Charleston. For New Yorkers also are traduced and misunderstood. Their evil all report, their good qualities few recall.

Yes, they need Phil Conley to come to their rescue and let the world know that after all is said New York City is as good as Kanawha, Fayette, Boone, Raleigh, Logan and Putnam counties in West Virginia and that having a larger and so a more adequate police force it has a better, if indeed not any too complete, a hold over its small but active criminal population.

Rotherham Rescue Station, Rotherham, England.

Coal Mining Institute Seeks

Cure for Frequently Recurrent Mine Explosions

Ryan Gives an Account of His European Trip — Ashley Seeks Simplification of Coal Standards and Holbrook a Standardization of Mining Equipment — Chester Describes Air-Conditioning Apparatus

SHOT through and through in every part of the sessions of the Coal Mining Institute of America in its meeting of Dec. 19-21 in Pittsburgh and vicinity was the thought of safety provisions against the recurrence of the many mine explosions which recently have caused a large loss of life. The study concluded with a visit to the U. S. Bureau of Mines' Experimental Mine, where a test explosion gave once again conclusive evidence of the dangers of coal dust.

Alterations to the auditorium of the Chamber of Commerce Building, in the downtown section of Pittsburgh, which for several years has been the meeting place of the Coal Mining Institute of America, shifted this year's sessions to the lecture hall in the building of the U. S. Bureau of Mines. On the first day about 100 men attended the morning session and 250 men the afternoon session. H. D. ("Joe") Mason, secretary and treasurer, reported that the institute has been swelled to an enrollment of 2,631 members by the addition of 543 new members, 180 of whom were obtained by President Richard Maize. He reported that the bank balance was \$2,139.78 including \$1,000 in Liberty bonds. The total expenditure during the year was \$5,112.03. The tellers declared that M. D. Cooper was elected president and Nicholas Evans, Richard Maize and Dr. E. A. Holbrook were elected vice-presidents for 1924. The vote also showed that H. D. Mason had been elected secretary-treasurer.

After a brief address from the president, Richard Maize, in which he gave his ideas as to "What is the matter with the coal business," Dr. George H. Ashley, state geologist, of Harrisburg, Pa., delivered an address on "A Practical Classification for the World's Coals,"

in which he assumed 7 per cent as the normal ash and divided the coals according to their percentages of fixed carbon, equating those portions of the coal which were not ash to 93 per cent. He classifies the coals according to their carbon content, each class covering a variation of 7 per cent in that content. Thus midvolite was 63 per cent of carbon, and the classes above and below are lovolite, with 70 per cent of carbon, and hivolite, with 56 per cent.

The various classes of coal according to Mr. Ashley are anthracite, semi-anthracite, loorvalite, lovalite, midvolite, hivolite, hiervolite, moistvolite, himoistite and lignite. A committee was appointed to confer with Mr. Ashley relative to the preparation of a coal classification, the membership of which is as follows: A. C. Fieldner, U. S. Bureau of Mines; W. E. Fohl, consulting engineer; A. R. Pollock, general manager, Ford Collieries Co.; E. A. Holbrook, dean, School of Mines, State College, Pa.; F. B. Lockhart, coal broker, and J. J. Rutledge, chief mining engineer, Maryland Bureau of Mines.

In the discussion Dr. Ashley was asked if analyses could be used to identify seams and he replied most unqualifiedly "No," because the analysis of any seam varies greatly from place to place. W. L. Affelder asked why the coal in the upper part of the Pittsburgh seam is higher in sulphur than in the lower part. Dr. Ashley said he believed the cause of the phenomenon is leaching.

In answer to a question by W. E. Fohl as to whether coal can be classified as to caking qualities he said that actual test was required to determine that property. Dr. Fieldner approved of the simplicity of Dr. Ashley's

classification, as no figuring was needed in making use of it. He asked if the moisture content taken is that found in the coal when received, Mr. Ashley replying that for court cases it would be necessary to establish some standard specific method of determining the moisture content of the coal.

The first query in the question box was, "Does dynamite exert a greater force downward or does it exert the same force equally in all directions?" It was quickly answered, Jesse K. Johnson, of Bolivar, Pa., leading the discussion.

W. L. Affelder asked if tests have been made to determine the relative directions of force. C. S. Jones answered that dynamite in exploding acts equally in all directions. J. E. Crawshaw, of the U. S. Bureau of Mines, referred to Dr. Monroe's tests in which blocks of compressed guncotton were detonated on and under iron plates. The same results were obtained in either case. Dynamite produced the same relative effect in blocks of lead regardless of its position with respect to the sides of the cube.

Dr. E. A. Holbrook, of Pennsylvania State College, explained to the meeting the work of the American Engineering Standards Committee, formed in New York to standardize materials and practices (1) in general engineering, (2) at sea and (3) in the mines. He said that the national engineering societies are behind the move. The purpose of his committee is to study and formulate rules for explosives, underground electrical systems, safety lamps, etc.

As chairman of the committee on the correlation of mining materials and practices, he invited the institute to appoint a committee of two to work with his committee. Its main aim is to set standards of safety. The committee appointed consisted of Thomas A. Mather, state mine inspector of Tyrone, Pa., and Rush N. Hosler, superintendent, Pennsylvania Rating Bureau, of Harrisburg, Pa., with Dr. E. A. Holbrook as chairman.

J. T. Ryan then read his paper on "Some Observations on Mining in Europe," using about a hundred

lantern slides. He laid much stress on the safety methods of Europe, especially in regard to the avoidance of coal-dust explosions. He said:

"One of the outstanding safety measures in Great Britain and France is corrective of the hazard of coal-dust explosions. This subject has been given much attention and study by their technical and research men. Their investigations have determined that it is impossible and impractical under their conditions to render coal dust inert by wetting, and these conclusions were the basis of general regulations effective July, 1920, in Great Britain, which are as follows:

"(a) That the roof, floor and sides of the roadways, to within 10 yd. of the working face in dry and dusty mines shall be treated with incombustible dust, so as to insure that, throughout, the mixture does not contain more than 50 per cent of combustible matter; or

(b) They shall be so treated with water as to assure the dust being always combined with 30 per cent, by weight, of water in an intimate admixture."

"Rapid compliance with the provision has been given and, in consequence, in many instances roads are being stone-dusted right up to the working face. In my opinion it will be impossible for an explosion, once initiated, to extend any great distance in any mine complying with this regulation. The mine inspectors check up the condition of the dust by taking samples from the roadways, which samples are then analyzed by the Mines Research Testing Station.

"In France, regulations are somewhat similar, except that the dust must contain 70 per cent of incombustible matter, as against 50 per cent in the British regulations.

"Our practice in this country at the present time has been to depend upon wetting or humidification. In Europe they do not think this is dependable enough. There is one good reason, however, why they cannot resort to humidification in many of their deep mines, and that is the temperature, for at the present time it is about at the limit in which men can work. The temperature in some of the mines runs from 75 to 85 deg., and if air that warm were highly humidified, it would be impossible for men to work in it.

"Another important safety precaution taken in those European countries is the almost exclusive use of closed lights. In Great Britain in 1922, with 921,737 men employed underground, there were in use 584,404 flame safety lamps, 294,593 electric hand lamps and about 2,000 electric cap lamps. The British were slow to take up the electric lamp, but they are now rapidly replacing the flame lamp, and the electric cap lamp is just beginning to come into favor, and Scotland is the country that is showing this sign of progress.

"Rescue apparatus and mine-rescue training is made compulsory by regulation in all of these European countries, and in Great Britain these regulations date back to 1913. Briefly, they require that all coal mines and all oil-shale mines shall have the protection of approved rescue apparatus and trained brigades. Each mine may have its own individual rescue station, the number of men to be trained being regulated by the number of employees, or a group of companies may combine to form a central rescue station, the requirements being that this station maintain a permanent rescue corps which will serve all mines within a radius of ten miles from the station. The central rescue station is popular and most of the mines operate under such protection."

In the discussion of the paper Mr. Ryan was asked

JOHN T. RYAN

Mr. Ryan came back from Europe convinced that that continent was on the right track in advocating and enforcing the stone-dusting of mine entries.

COAL MINING INSTITUTE OFFICIALS, 1924

From left to right—Richard Maize, president, 1923; vice-president, 1924; M. D. Cooper, president; Nicholas Evans and E. A. Holbrook, vice-presidents.

if rock dusting could be used to advantage in the United States as it is in Europe. Mr. Ryan replied, "Absolutely." He said that the argument for stone dusting was well exemplified by the conditions at the mines of a company in an arid region of this country. There a complicated humidification system had been installed which will cost 29c. per ton of coal mined. Rock dusting would not cost more than 5c. per ton.

Question 2, "Which type of safety lamp wick gives a flame that is the more sensitive to gas—the flat or the round wick?" being presented, J. W. Paul, of the U. S. Bureau of Mines, remarked that with 2½ per cent of gas the round wick and with 3 to 4 per cent the flat wick gave the better showing. At low percentages there was no difference.

Question 3, "Is radio proving of any practical use in coal mining or for mine rescue work?" was answered by J. Jackowsky, of the U. S. Bureau of Mines. Mr. Jackowsky said that the telephone was a satisfactory way of transmitting messages except after an explosion, and it was hoped that radio might be developed to serve in its place under these conditions, but practically none of the present apparatus is sufficiently moisture- and water-proof for continuous exposure to the mine atmosphere.

A radio receiving set that had been left underground for about six hours became exceedingly inefficient. The Bureau of Mines has been using (1) ground-conduction methods; (2) induction signaling of both high and low frequencies; (3) wired radio over underground power and telephone lines, trolley wires, rails and pipes; (4) radio; and (5) electrical geophone and auxiliary signal equipment. In Mr. Jackowsky's opinion wired radio utilizing compressed-air or water piping, car rails, etc., as the conducting media is to be preferred. Dirt and water over these conductors and numerous breaks on the metallic circuit do not prevent the transmission of signals.

At the banquet in the evening speeches were made by Dr. Daniel L. Marsh, Captain Irving O'Hay and a comedian representing himself as the Hon. Abe Potash, a coal operator of Brunswick, N. J. The addresses were

unusually notable, Captain O'Hay especially ingratiating himself with his audience.

At the morning session of Dec. 20 W. E. Fohl, as chairman, opened up the meeting with a discussion of question 4, "What precautions should be taken in the installation of an electrically driven exhaust fan at a mine giving off methane, to prevent the gas in the return air from becoming ignited by the motor when re-establishing ventilation after the fan has been stopped for a sufficient time to allow the mine to fill up with gas?" The report of this important and lengthy discussion will appear in next week's issue.

The next question was: "What is the practical limit to the splitting of air currents?" D. N. Hubbell, mining instructor, said that the splitting should be done so as to supply at least the legal quantity of air to each split but also so as to afford each split enough air to prevent harmful accumulations of deleterious gases. Within these limitations he would advise as much splitting as possible, as splitting reduced the resistance of the air.

The sixth question was:

"What changes in roof, bottom and coal are met when approaching a fault?" Joseph Williams, state inspector at Altoona, Pa., said that petrified wood often was found when approaching faults in the First Coal Basin and Dr. Thiessen requested that such finds be sent to him. Much petrified wood is found in Europe but in the United

States such material was unusual. He would be much pleased to have an opportunity to examine it. Mr. Williams was of the opinion that the wood was of a date much more recent than the coal which was faulted.

Speaking of "faults" of erosion, or wants, R. D. Hall said that as they were excavated in the seam they often were accompanied by drift matter which had lodged as drift wood even now does at the bank of a stream. This drift has later been filled with shales or sands and as a result the coal is covered by material filled with vegetable matter. This material gave a most uncertain roof and he recalled a man being killed in a heading purposely driven narrow toward a want. The material which fell was full of the imprints of ferns. He had noted that as a rule in a certain want the ferns lay, not as they had fallen, with the maximum diameters in all directions, but as they had been rearranged by the stream, with their major axes in the direction of stream flow.

He added that at this particular want the coal at one place suddenly thickened from 3 to 6 ft., as if the bed of peat had been torn away bodily and dislodged, landing entire on the top of another area of eroded peat. Without attempting any accuracy he thought the area of the displaced and deposited peat block would cover roughly an acre.

Joseph J. Walsh, Secretary of Mines, State of Pennsylvania, then addressed the institute on "Mine Fires and Some Methods of Extinguishing Them." He advocated the use of flue gas as cooled in a tubular cooler and then sprayed by falling water. He said the

W. E. FOHL
Consulting mining engineer,
Pittsburgh, Pa.

purpose was to supply so much incombustible gas that no air could enter the fire area. He believed this to be possible if the right precautions were taken to close in all openings as far as could be arranged. He advocated closing the return first and never the intake. He said that there had been twenty - seven coal crop fires

JOSEPH J. WALSH
Secretary of Mines, State of Pennsylvania; advocate of flue gas for extinguishing mine fires.

in the anthracite regions; one was sixty years old, one twenty years. However old they might be, none of them had hitherto been extinguished and many means had been tried in every instance—flooding, direct fighting and sealing. One mine was sealed for eighteen years and no sign of any fire remained till an attempt was made once again to enter the fire area. The fire that had slumbered for years then awoke again and soon raged as menacingly as ever. He declared that, with 100 per cent excess air in the furnace, flue gas containing 5 per cent of oxygen could be generated, and in such an atmosphere no fire would continue to burn.

In the afternoon session of Dec. 20, Thomas Chester, Mining Engineer, American Blower Co., Detroit, Mich., read a paper entitled "New Data Concerning the Humidification of Mine Air," in which he described the Lide method of conditioning air and driving the air thus treated by an auxiliary fan into the intake entry fan drift would have to be concrete.

The conditioned air is at the temperature of the mine and fully saturated at that temperature. Mr. Chester said that the conditioning of air had been proved possible in the manufacture of matches, where the heads were dried in a factory the air of which had been conditioned. It had also been used in motion-picture film factories.

Questioned as to the cost, he said that an installation to condition 100,000 cu.ft. of air per minute would cost, including the fan but exclusive of the second drift opening, about \$3,000. The operating charge would be equivalent to the cost of about 0.6 ton of coal per hour plus the labor involved, which would be small. In addition there would be the power involved in driving a 10-hp. motor, which would be ample, as the water gage needed to drive the air through the conditioning apparatus would be about $\frac{1}{2}$ in.

Mr. Chester said that stone dusting the entries would not solve the problem of making a mine safe, for the fine dust tended to settle not in the main entries but rather in places where the current was relatively sluggish. The high-speed currents dried the mine and also carried the dust. Thus in the more quiet places the finest and most dangerous dust was constantly being deposited.

Asked whether it would be necessary to concrete the fan drift he replied that no great heat was required at

any place and consequently the natural strata did not tend to disintegrate. For this reason no part of the fan drift would have to be concreted.

He also said there would be no fog if the temperature of the conditioned area was kept continuously at 60 deg., for it would then be at the temperature of the mine itself. This would not wet down the mine, for the air would never be supersaturated, but it would prevent the mine once wetted down and containing natural moisture from drying out.

Should the pressure of the fan of the conditioning apparatus be made high enough to compel the air to leave by the portal of the mine, this air, being cooled in winter by the outside air, would cause a fog at the drift or shaft mouth. The same fog would be caused there as at the chimney of the main fan, but as it would be a surface fog it would not occasion inconvenience.

He declared that when no men were in the mine the air could be conditioned to a temperature of 75 deg. In that case a fog would be formed, as the mine would not sustain such a temperature. Under these circumstances the mine would become wet with water dripping from the air. It might be well to condition the air at this higher temperature out of working hours.

J. W. Paul said that the injury to the roof by the crude methods of moistening usually adopted was due not so much to the heat as to the changes in temperature, which caused the roof at one time to expand and at another time to contract.

He added that even where the air was incompletely saturated it had been found that droppers and globules of water appeared in the roof. These globules were frequently ascribed to water deposited by condensation, but he believed that in most cases, as the air was not saturated, they came from the moisture of the workings themselves. Edward Steidle believed that rock dusting might profitably be used in connection with some such process of air conditioning as Mr. Chester had described.

Under the leadership of Nicholas Evans, state mine

M. D. COOPER
Newly elected president of the institute; assistant general superintendent, Hillman Coal and Coke Co.

inspector, of Johnstown, Pa., three questions were considered. The first of them was: "Where does the most dangerous dust lie—on floor, ribs or timbers?"

One of the members connected with the Keystone Coal Co. said that he had sprinkled his roadways day and night and still they were not as damp as he would wish. He thought the haulageway dust the most menacing of any. R. E. Kirk said that since the Gates disaster the H. C. Frick Coke Co. had classified its mines into dusty and non-dusty mines, and in the former allowed no shooting off the solid and required that the room be sprinkled before cutting, before shooting and after shooting.

J. O. Durkee said that at the mines of the Bethlehem Steel Co. the dust at the face was the cause of the greatest apprehension. Water cars and the sprinkling of coal cars took good care of the haulageways, but the rooms were kept free from dry and dangerous dust only with difficulty. In many of these, pipes had been carried to the working faces, and as a result the officials at the mine were able to keep the dust wet.

Someone from the Oak Creek Mine, Routt County, Colorado, described the conditions at that mine, where the men could not see one another's light across a 40-ft. face. Now by the use of a sprinkling line on the cutter bar the dust is satisfactorily wet down so that it is no longer dangerous.

Nicholas Evans much regretted that any one should have invented the use of the word "sprinkling" because "drowning" the dust was what was intended. Mr. Paul said that as the finer dust was the more sensitive to explosion it was the kind most to be feared. It lodged in gobs and on timbers and was exceedingly dangerous.

The dust on the lower half of the mine rib in steep and mule-haulage roads and especially on those that were wet was relatively harmless. In fact in some mines the ribs are splashed with mud for some distance from the floor. It must be remembered that two one-hundredths of an ounce of coal dust per cubic foot of entry will be enough to make an explosive mixture of coal dust and air. This much dust would just cover a silver quarter.

The British requirement of 30 per cent of water in a place which did not have to be sprinkled was a requirement with which few sections of any mine could comply. All the recent explosions in Great Britain have been in damp places, and these have been stopped only where shale dust areas have been reached.

Question 9: "What are the most common causes of the ignition of gas in coal mines?" was answered by

THOMAS CHESTER

Advocated that the air entering the mine be conditioned as to moisture and temperature so that it would keep the mine wet yet free from fog.

that was ignited by safety lamps which were either defective or unlocked, and 400 by ignitions of gas or dust by electric arcs. Two hundred men had been killed by explosions due to ignition of gas by men who were smoking or preparing to smoke. He said that all open lights should be abolished.

A spirited discussion arose as to Question 10: "How tight should posts be set in rooms and entries?" Crawford Wilson remarked that the height of the seam, the nature of the overburden and the pitch had much to do with the problem. He believed that props should not be set too tight but certainly should be set sufficiently snug that they would not be knocked out.

Edward E. Girod, state inspector, of Masontown, Pa., remarked that some persons put in props so tight that they were almost broken by the strain of setting. Some men put up a prop and fail to make it tight, expecting later to wedge it tight or hoping it will get tight later. That also is wrong, as someone or something may cause it to fall, with consequent injury.

Still it is dangerous to prop a roof that has sagged or drawn, so as to lift the rock. The strain of forcing the rock back into place may cause it to break. It would be more permissible to post solid rock tightly. He recalls a case where a foreman was extending a side-track and making the roadway wide for that purpose.

The foreman put a row of extremely tight posts up the center of the roadway. Mr. Girod warned him of the consequences. Some time after about 180 carloads of rock were removed and about 200 more were lying in the roadway. The props had broken the drawslate.

About 200 members attended the demonstration of Dec. 21 at the U. S. Bureau of Mines' Experimental Mine, Bruceton, Pa. An explosion of dust from the West Kentucky Coal Co.'s No. 9 mine was successfully produced by a blown-out shot in which 4 lb. of black powder was used. The tunnel was provided with 1 lb. of the dust described per lineal foot of entry, 20 per cent of the dust passing a 200-mesh screen. The flame shot 400 ft. beyond the dust bed, but was stopped by a Rice barrier. No gas was present to aid ignition.

A test was made to show that permissible explosives used in proper quantity will not ignite dust. Powder was tested also with the ballistic pendulum. Another test showed how a keg of black powder could be ignited by contact with electricity, and another exhibited the fact that coal dust blown into the air may be ignited by an ordinary flame.

A station that would cost in America about \$300,000.

It Is Easy to Waste Money on Mine Supplies

Buying More Stock Than Is Needed and Allowing It to Depreciate on Hand a Costly Leak in Many Organizations—Computing That Cost a Little-Known Science But Worthy of Close Attention

BY NEILL HUTCHINGS
Birmingham, Ala.

WHAT is the cost of carrying a stock of supplies at a coal mine? And, more important, what is the cost of carrying too much of such stock?

Here is one of the important cost elements of business, yet it is a little-known element because it is rather intangible and difficult to put into figures. Many a wide-awake mine manager gets a more or less definite idea of whether he has on hand too many machine parts, too much wire rope and the like, by watching turnover. But even a live manager may not realize how much the company suffers by losing the working value of dollars expended for dead material. Nobody has worked out an exact system for him to follow, but it is worth while for every mining company to study the matter. An illuminating statement on this subject was made recently by a man who since the close of the war has engaged in reducing and liquidating the inventories of one of the largest concerns in our country. He says the cost of carrying money in excess and undesirable stores and supplies rather than in active business amounts to as much as 3 per cent per month! This is 36 per cent a year and means that for every dollar's worth of supplies bought and kept for a year, 36c. is lost. For every \$100 worth the loss is \$36; for every \$1,000 worth, \$360, and so on. This cost is made up of such factors as the earning power of a dollar actively employed in the business, losses from depreciation, obsolescence, shrinkage, expense of handling, caretaking, watching, renting, accounting. In addition, there is the cost of added storage room for surplus material and the waste in use which naturally comes from having plenty to draw on, thus dulling the exercise of economical use of supplies and materials.

This man probably has come very close to computing the cost of carrying dead stock. If he has, then no doubt many concerns are losing big money. For an inventory devoid of surplus, obsolete or excess material is hard to find nowadays.

There are two schools of thought regarding the charging of supplies and materials to mine costs. One, which is the older method, is to charge cost with materials as they are purchased. In this plan there is no inventory of stock on hand. Everything is charged out. Many of the older men in the mining game remember when this plan was general. A man thought twice before he signed an order for a carload of costly supplies. He knew his cost would have to stand it. This was the plan's best feature, for the cost sheet of

a coal mine is its manager's pocketbook. He wouldn't buy until he had to.

But it had many objectionable features. One month's cost was charged with materials used in later months. Such a plan destroyed comparative cost value. It really meant that only yearly costs reflected facts. A man could not tell what his cost would be from month to month and so he never knew exactly the relation of his income to outgo for any given month.

This older plan has been supplanted by a generally modern one founded on the principle that monthly cost should be charged only with materials actually consumed and used in that month. It is the better plan of the two. Still its practice value has certainly been less-

ened by the fact that mine managers who always pay chief attention to the cost sheet have paid too little heed to the volume of cash tied up in stock.

This modern plan requires a stock inventory. It has been, and always will be, the most natural thing in the world for the operator of a mine to insist that his storekeeper keep on hand all the things the mine will need, not only for current operations but for every conceivable emergency. He feels about his storehouse stock like the man in Texas used to feel about his gun. He did not need it often, but when he did need it he needed it bad. So under this method stocks grow. Instead of ordering one or two pieces of repair parts the buyer orders a half dozen. Maybe they come a little cheaper that way. Instead of one month's supply the storekeeper is told he had better order two, the excuse being "We will use it anyway and you'd better keep plenty on hand." This plan as a rule soon accumulates some excess, surplus, semi-obsolete and even worthless stock on hand.

Yet this plan is right. Cost should be charged only with the materials used in each cost period. It is the correct principle. But it does mean eternal vigilance over plant requirements carried in inventory. What is really needed to make the plan more nearly perfect is a definite system of ascertaining the cost of carrying stock.

Calculating turnover is a good way of getting at stock carrying costs but this process involves innumerable factors, such as proximity to market, seasonal requirements and variations in market prices as affecting purchases; so turnover is, after all, only a rough guide.

Applied common sense is the essential thing. By this is meant the use of common sense to determine how

FIND OUT

Does your mining company lose \$360 every year on every \$1,000 invested in mine supplies in stock? In this article an authority is quoted by Mr. Hutchings as saying that this astonishing rate of loss is suffered by many a concern. The fact that few mine managers know what their dead-stock losses are is reason enough to convince them that they should *find out*. There are suggestions here to guide them.

much stock of this and that shall be carried. Somewhere in every mining concern big enough there is a man with this kind of sense. Applied common sense simply means putting him at work on the problem. He is the fellow who sooner or later will prove what a dollar invested in dead stock costs. This fellow will show how poor a guide turnover is, by proving that in a majority of stocks 75 per cent of disbursement value is for material representing less than 25 per cent of total stock. He will do more than that. He will search out the excess and surplus and scrap it or sell it. By hard work he will determine, item by item, the lowest possible limit to carry without hurting operations. That really will be the cream of his work, for it is the only practical thing to do.

An operator can not set an average cost for the stock as a whole. His "common-sense man" will eventually keep him from buying excess supplies. That man will soon be authorized to O.K. all purchasing orders, both to see what he can do in the way of substitution for materials already bought and to buy less than somebody has ordered. He won't let the company buy anything that *might* be needed. The cost of this is too high. It is too much like letting a man name his own salary regardless of his ability.

The cost of carrying surplus supplies is an intangible thing and probably it is not a definite cost figure. Even if we assume 3 per cent a month to be entirely too high and call it 2 per cent a month, some very interesting calculations can be made. For example, suppose a mine concern has a total inventory of supplies of \$500,000. Assume further that the excess stock—i.e., supplies bought and on hand in advance of actual need—is \$50,000. Then it follows that the monthly cost of having this surplus stock is \$1,000.

Carry this thought further along and think of two concerns having this same amount of surplus stock. They begin to liquidate it at an even rate. The one that can get rid of it in six months while the other takes twelve will save \$6,000 more than the latter. This is the earning power of the money released by this process.

ALL LIKE TO PICK NEW "STUFF"

In connection with this thing of too generous buying, carrying surplus supplies and suffering actual monetary loss as a consequence, it is not surprising that American industry, like present-day individuals, has wandered far afield from old-fashioned thrift and saving principles. It is not an uncommon thing to find even at the most modern mining plants a lack of care in providing proper storage facilities for supplies. Costly wire rope sometimes is exposed to weather until some of the strands have rusted through. Iron and steel stock often is left exposed until rust has pitted and injured it so badly that it is useless. It is a natural instinct with all of us to like to use new and shiny material. Mine mechanics, electricians and blacksmiths will take the newer stuff every time if they can get it. It pays to keep material in attractive condition, lest it be left to spoil.

Another thing productive of considerable economy in the storing and handling of mine supplies is to concentrate. Don't permit supplies to be scattered all over the mine plant. Put them in one place, as much as possible inside a central storehouse building, and the rest under fence right around it. To permit materials to be unloaded and stored just anywhere that happens to be convenient is to deliberately invite loss. The stock

is likely to be used indiscriminately, stolen or allowed to suffer by reason of neglect.

Protect heavy supplies that must be kept in the open, from weather. Both sun and moisture are directly detrimental to certain materials. Light, for example, has a tendency to rot belting. Consider mine supplies as just another form of money and treat them as money.

Mine foremen, electricians, mechanics, blacksmiths, superintendents, managers, can do their concerns a lot of good by studying closely the care and use of mine supplies and materials. After all is said and done, they are the men who create stock, and if there is such a loss as 2 or 3 per cent a month on surplus and excess stores, they are the men responsible for it. Next time one of these men orders or draws a requisition, possibly he can do without something he is buying and cut down the order to fit immediate needs. It will reduce the stock-carrying loss and will increase the worth of that man to the concern and enhance his own self-respect. In fact, whenever a man learns to work for a concern and care for its dollar as much as he does for his own earnings, he has started on the trail that leads to his own individual success.

Electric Signaling Devices

Mines Operated Electrically Must Adopt Electric Signals—Signals for Emergency and Time Calls

By T. R. HAY

WITH the gradual passing of steam drives for machinery around the coal mines and the increased application of electricity to old and new fields there has arisen a necessity for some efficient type of signaling device for alarms or for other purposes.

The natural trend of development has been to electrically operated sound signaling, as such a device can be made automatic, may be installed in any location and operated with but a limited amount of attention.

The electric siren with its peculiar penetrating quality of tone gives a distinctive call for help—a fire emergency or danger signal—that is instantly recognized as such. Its very sound is a warning, a rallying call for assistance, because it is so different from all ordinary factory whistles, fire bells or other alarms. The application of an electric signal does not find itself limited to the field of emergency calls, but in many

places it is used to great advantage as a time signal.

At coal-mining operations a whistle may be used as a work signal, an emergency fire or accident signal, or for both. At many coal-mining operations the miners often live at a distance from the mine workings. Because of the distance element, there may

FIG. 1—SINGLE-HORN SIGNALING DEVICE

Some of these signals are made with two horns, one on each end of the drive shaft. The small sizes have one horn, and the largest sizes two horns, in this style of construction.

be more or less irregularity both in starting and quitting work, especially the former. With, say, 100 men employed, if an average of 50 per cent are tardy ten minutes each day in starting to work, 500 work minutes, or $8\frac{1}{2}$ hours per day, are lost. This comes to something over 160 work hours per twenty-day month. In terms of tonnage lost due to tardy attendance, this means a considerable item over a long period. Punctual attendance is worth real money. In the winter period, when coal is in demand, when the price is relatively highly, and when, on account of uncertain car supply, it is desirable to make maximum use of the hours when the mine does work, this matter of punctual attendance becomes more important than in the summer months, when demand and price are relatively low and car supply fairly dependable.

PROVIDE PROTECTION AGAINST WEATHER

The electric siren whistle consists of a small motor with the shaft extended on one or both ends, depending on whether it is of the single-head or the double-head type. A slotted aluminum rotor on this shaft extension revolves under a conical-shaped steel slotted "horn." The air is taken in at the ends, which are of cast iron, and the sound comes out on the periphery of the "horn." A sheet-steel cover, usually bolted to the horn or horns, protects the motor and bearings from rain or from any foreign material. The motor leads are brought out through this cover, which for one type at least is permanently fixed in position. Oil cups, located on the outside of the case have spring caps, thus making oiling convenient and at the same time protecting the bearings and keeping the oil free from water. The motor base

FIG. 2—SIGNAL IN POSITION

For long-distance service, it is important to mount signals well up in the air so that the sound waves will not be reflected by buildings or other structures.

is substantially made and is of cast iron.

The siren commonly used about coal-mining operations is made in the single-head and double-head types. The single-head siren can be heard over a radius of approximately three-quarters of a mile. The double head siren, which is the one most commonly used, can be heard over a radius of a mile and a half to two miles. At many installations the siren can be heard a greater distance than stated above.

For best results the siren should be installed at least 40 to 50 ft. in the air and 10 to 15 ft. above any roof or other flat surface. It should

FIG. 3—A LOCAL SHORT-DISTANCE SIGNAL

Where the signal is to be used for short distances and yet be heard over the noise of running machinery, the above type frequently is used. Hoisting signals operated electrically give most satisfactory service at the coal mines.

be above near-by buildings or trees. The reason for such installation is because a roof or other flat surface directly below a siren acts as a sound-board and throws the sound waves up in the air instead of distributing them over an extended area. A good method of installing sirens is to set them on a crosspiece or tripod connecting the tops of two or more telegraph poles. The siren may be located on the top of a mine tippie, above the hoist sheave, or on a platform above a flat tippie or substation roof. The axis of the siren should be at right angles to the direction in which it is designed to distribute the sound. This is because, as previously explained, the air is taken in at the end through the cast-iron "horn" and the sound is forced out at right angles through the steel slotted portion of the "horn."

The siren may be operated by means of a knife switch located in the substation or at any convenient point. It also may be operated by means of a remote-control device, consisting of two or more "start" and "stop" momentary contact pushbutton switches, together with a magnetically operated circuit breaker. The use of this remote-control switch device enables the starting and stopping of the siren from more than one locality, such as the tippie, the substation, the superintendent's office or commissary.

The tone of the siren may be varied and a "wildcat" call obtained by manually opening and closing of the control knife switch. This "wildcat" call may be obtained automatically by using a motor-operated make-and-break switch. To get the proper effect, whether by hand or automatically, it is necessary to allow a sufficient time interval between the breaking and making of the motor circuit to enable the siren to slow down sufficiently to give a distinct tone difference.

The single-head siren weighs approximately 250 lb. and the double-head siren weighs approximately 350 to 400 lb. The siren is simple in design and construction and can be connected up without any special difficulty. All that is necessary is to install it on a secure base and connect the motor leads to the power supply. These sirens are supplied to operate on single phase, 110 or 220 volts, and polyphase, 110 to 550 volts. They can be used on either 25- or 60-cycle circuits.

Sirens also are furnished to operate on direct current

of any voltage, from 110 to 600 or 700. Operation on any phase a.c. or on d.c. at 220 volts or more is preferable because of lower starting current and better voltage regulation. The single-phase siren is equipped with a repulsion type motor with brushes; the polyphase siren is equipped with a squirrel-cage induction type motor; and the direct-current siren is equipped with a series-wound d.c. motor.

Coding or call signaling can be obtained with greater satisfaction with the polyphase a.c. motor or the d.c. motor than with the single-phase motor. The last-named type is not so satisfactory as the others because it is necessary for the brushes to lift from the commutator in order to obtain satisfactory tone effects. This requires that the siren slow down too much to give the desired results.

In addition to the single- and double-head siren discussed above, a small siren designed for local use, which can be installed indoors or outdoors, is manufactured. It is distinct in tone and because of its construction there are no parts to wear or get out of order. It has only two bearings, one at each end of the armature shaft with oil cups of sufficient capacity to require oiling only two or three times a year. The sound penetration is approximately 400 yd. and it is being used with success at many coal-mining operations where only local sound penetration is required.

Ejected Cement Gives Life and Strength to Mine Structures

Stoppings Readily Constructed with Concrete Sprayed from Nozzle—Gunite Frequently Substituted for Concrete in Lining Shafts and Slopes

BY A. F. BROSKY

Assistant Editor, *Coal Age*, Pittsburgh, Pa.

OF RECENT years projected concrete has been extensively used in the building of stoppings for ventilation or for sealing abandoned workings. Of the many types of stoppings constructed with the use of this material perhaps the most common one is a pack wall of slate or sandstone laid without mortar and sealed by shooting it with gunite on one of its exposed faces. Care should be taken to form an airtight seal, especially around the outer edges of the stopping. This is accomplished by extending the coating material beyond the points of contact by shooting the liquid mass over the ribs and roof. In consequence no air can pass through the coal at the side of the stopping or through the roof at the top of it.

Permanent and airtight stoppings are built in the Tropic mine of the Tropic Mining Co. (Ohio) by fastening a reinforcing mesh on props wedged so as to stand vertically against either rib. Behind this mesh is placed tar paper, which serves as a backstop for the shooting of the gunite, which is projected to a thickness of 2 in. After standing five years these stoppings are as intact as the day they were erected wherever the roof has held up. Under weak roof it would seem that a thicker wall would be desirable. In that case an alternative method of construction may be utilized.

Stoppings are erected in the Wolf Summit mine by setting two prepared wooden forms at a distance apart equal to the thickness of the stopping desired, which usually is 8 in. The box thus formed is filled from the top with gravel. The nozzle of the gun is then inserted

downward from the top, and the gravel is impregnated with gunite. After this wall sets the forms are removed elsewhere and the openings at the joints are closed with gunite. This stopping can be erected in 45 minutes of actual working time after all the material is on the job. The completed stopping is shown in Fig. 1. A similar construction (Fig. 2) was utilized in adding a vertical section of 6 ft. to a curtain wall in the shaft of this mine, which was left open at the bottom during the early stages of development.

SEAL OFF WATER AND GAS WITH GUNITE

Gunite also was used at this mine to form water dams and to seal off gas. Large quantities of this gas escaped from falls of rock, the roof breaking under the pressure of the gas pent up in feeders. The dams were placed at the dead ends of the two headings and were made 30 in. thick. They were built solid to the roof and ribs in the same manner as the stoppings already described. Behind these dams are water springs and also feeders of gas which showed 28 per cent of methane in tests made before the construction work was completed. This gas which repeatedly caused the limestone which is 15 ft. above the coal to break and fall was bled by boreholes drilled from the surface. The bottom is of soft clay overlaid with a harder material which leaks where broken. Consequently water seeped under the dam and through the fireclay and ran down the dip to lower workings. This seepage will be closed off by drilling vertical holes to a depth of 12 ft. and injecting gunite through them. The water accumulating behind the dams is piped to an open ditch.

Open ditches on the surface in hydraulic projects frequently are lined with gunite and this suggests another use for it underground. Where mine drainage on a large scale is accomplished by open ditches as it is in the mines of the Berwind-White Coal Mining Co., situated in the Wilmore Basin, at Windber, Pa., gunite, besides reducing the resistance to flow, would also facilitate the cleaning of the ditches.

USE OF GUNITE IN SINKING MINE SHAFTS

Shafts sunk through self-supporting formations, which, however, disintegrate in time may be lined with gunite instead of concrete wherever the water problem is not serious enough to require sinking under pressure. The engineers of the Oliver Iron Mining Co., at Hibbing,

FIG. 1—GUNITE-GRAVEL STOPPING AT WOLF SUMMIT

The stopping was made by erecting two forms and filling the intervening space with gravel, which was then grouted with the cement gun. The forms were removed after the mixture had set, and gunite was then placed on the exposed face, making a strong, tight and permanent stopping.

FIG. 2—CURTAIN WALL AT WOLF SUMMIT GUNITED

This wall is located at the foot of the shaft. One advantage of guniting is the ability to seal the edges and corners of the stopping where small leakages with other forms of bratticing allow much air to pass, especially where the water gage is at a maximum, as in this instance.

Minn., closely watched the action of guniting in preventing disintegration of such formation, and the results were so favorable that they are using it in sinking a shaft which will be lined by this method.

A reinforcing mesh is attached to expansion bolts placed on 30-in. centers on the face of the rock. Upon this approximately 2 in. of guniting is placed. This thickness is attained in two layers, the first being just sufficiently thick to come out to the mesh and the second being $\frac{3}{4}$ in. thick; thus the mesh is everywhere covered with at least $\frac{3}{4}$ in. of guniting. The first coating is allowed to set for several hours; it is then wetted down and the second coating applied.

When water occurs in the form of tiny streams or of thin films covering the surface of the rock it prevents the guniting from adhering. However, the small streams of water can be led to weep pipes and the guniting can be applied by coating the points away from the pipes first and then extending the coat toward them. Guniting can be applied successfully to a very wet surface by using a solution of sodium silicate (water glass) instead of water as hydrating agent.

ELIMINATES NECESSITY FOR TIMBER RINGS

To attach the guides, holes are drilled in the rock and in these expansion bolts are placed and grouted. Around these are built pads of guniting projecting sufficiently to act as seats for the base of the guide blocks. This provision eliminates the necessity of using timber rings around the walls of the shaft. Wooden buntons are placed across the shaft. These are attached to reinforced corbels built out with guniting from the sides of the shaft.

The cost of this lining is about 20c. per square foot not including the overhead. The cost of doing a similar job may be roughly estimated by bearing in mind that one bag of cement and 3 cu.ft. of sand will cover 11 sq.ft. to a thickness of 2 in.; that a crew consisting of a nozzleman and his helper, a gun operator and four laborers can apply each day at least 800 sq.ft. of guniting to a thickness of 2 in.; that the cost of drilling holes for bolts is approximately 5c. each; and, finally, that American Steel & Wire triangular mesh No. 068, or its equivalent, will cost about 4c. per square foot in place.

In many cases guniting may be substituted for concrete

in the lining of slopes. The extent to which it may be used on any one job depends upon the depth of the seam of coal below the surface and the nature of the overburden penetrated. Where a slope will stay open of its own accord, as in penetrating thick beds of clay and soft shales, obviously a concrete lining poured into forms must be used, as otherwise the requisite strength will not be attained, but where self-supporting shales and sandstones subject to weathering are penetrated, a guniting lining is used advantageously.

SLOPE HAS 1,200 FT. LINING

In 1918 the slope of the Wilson Mine, owned by the Acme Coal & Coke Co., was lined with guniting for a distance of 1,200 ft. It lies in rock which is subject to weathering when exposed to the air. This is especially true of such beds of fireclay as the slope penetrated. So far the lining has shown no signs of failure, which is a reasonable assurance that the work is permanent.

A more recent job of the same kind was done in the supply and manway slope of the Gibson Mine of the Hillman Gas Coal Co., at Weaver, Pa. For a distance of 550 ft. it was lined with concrete, the remaining distance of 200 ft. to the bottom being left unlined because the rock appeared to have sufficient strength. It was attacked by the air, however, and commenced to flake. The problem was solved by cementing the roof and sides with guniting.

Slopes driven through country rock to flat beds of coal expose successively the various bedding planes. Cracks develop at such points, and the weathering action is accelerated. The disintegration is more rapid in this case than where the slope parallels the bedding planes of the rocks, as in a synclinal basin. Consequently, in driving a slope under such conditions the guniting should be kept close to the face.

POSSIBILITIES IN CONSTRUCTION WORK

Guniting can be used in many places in underground construction and about the surface plant. Sumps already are being lined with guniting where the bottom is soft (see *Coal Age*, April 19, 1923). Overcasts if not built with guniting may be sealed with it where leaks develop. Disintegrated concrete linings in shafts have been successfully resurfaced with it wherever properly applied to a reinforcing mesh, which is used more to bind the coating than to give it strength.

An important use has been found for guniting in fireproofing small supply rooms, motor barns, pumprooms and other permanent underground stations in the coal. Open walls may be built to close in these stations by processes described in the construction of stoppings. On the surface the exteriors of wooden plant buildings and miners' dwellings may be plastered with guniting providing these are backed with a reinforcing mesh.

Where steel trestles are erected in a coal-storage yard, whether at the mine or at an industrial plant, the lower portions of the piers, which are likely to be buried in the coal, may be protected from abrasion and subsequent rusting by a coating of guniting. It is needless to state that moist coal with a high sulphur content will attack any steel structure that may come in contact with it. Paint offers little protection, as it is soon worn off. At Beach Bottoms, W. Va., the steel work in the yard in which was stored coal coming from a mine adjoining the Windsor central station of the West Penn Power Co. was gunited and in this way protected from abrasion and corrosion.

How Many Cars Should We Employ in Mines?

Number Is Based On Tipple Capacity, and Rightly, Because, If That Figure Is Exceeded, Cars Cannot Be Moved

IN DEVELOPING and operating a mine how many cars should be provided? The number of mine cars in actual use in a number of the mines visited is given in Table I. Though the number of cars at any of these mines is not by any means proportional to the capacity of the mine to produce coal, the variations, as shown, are evidently extreme.

As a matter of fact, the determination of the correct number of mine cars that should be available at any particular mine to transport the coal from the face to the tipple has been given extraordinarily small consideration from an engineering standpoint. It was with the greatest difficulty that the officials of most of the mines visited could be induced to discuss or explain in concrete figures the method by which they determined the proper number of mine cars for their own particular mine.

The problem of the proper number of mine cars may be viewed from two opposing points of view. The miner is primarily interested in having enough cars to furnish him with sufficient empties to avoid lost time. The management is primarily interested in enough cars to provide coal for a continuous operation of the tipple. The number of cars necessary for an adequate supply from the miner's viewpoint, when the mine is operating at capacity and under the present condition of understandardized operation, always is larger than the number necessary to produce continuous operation of the tipple.

Because of these facts, the management in most cases is largely governed by the rule of thumb that if, with plenty of labor and barring exceptional accidents, there are tipple delays due to "no loads," buy more cars, but if the tipple continues to operate steadily there are

Sixth installment of report on "Underground Management in Bituminous Mines" made by Sanford E. Thompson and associates to the U. S. Coal Commission. Previous installments may be found in *Coal Age* of Nov. 8, p. 691; Nov. 15, p. 733; Nov. 22, p. 773; Nov. 29, p. 811, and Dec. 6, p. 845. Other sections of this interesting report will follow later.

Table II—Estimates of Number of Mine Cars as Prepared by Mining Officials

	Mine A	Mine B	Mine C
On shaft bottom or outside stand			
Loaded trips.....	1 1/2	2	2
Empty trips.....	1	2	2
Main-line locomotive trips per locomotive.....	1	2	1
Trips per parting.....	1 1/2	1/2	1 1/2
Gathering trips per gathering locomotive.....	0	0	2
Cars per loader.....	1/2	1/2	1/2
Cars under repair.....	12	40	20
Cars for loading rock.....	20	100	15
Total cars figured.....	562	602	632
Number of loaders on which estimate is based.....	298	275	240

plenty of mine cars, even if the miners and foreman may call loudly for more.

Some general managers were candid in outlining such a policy as the determinant of their car supply; others stated that two cars per loader was a rule that worked well in the mines of their district and they bought cars on that basis. Those executives who were finally prevailed upon to furnish data for the determination of the correct number of cars for a particular mine in general based their results on the consideration of eight points, and three typical examples are shown in the Table II.

The principal unit used as a basis for figuring the greater part of the necessary mine cars was the trip, by which in this case is meant the maximum number of cars hauled by one haulage locomotive at one time.

Table III represents the actual condition at time of visit:

This unit, therefore, has been given in making up this table as its variations represent the only real basis of comparison between the methods of figuring cars at different mines. The number of cars in a main-line trip at Mine A was 30; at Mine B, 25, and at Mine C, 22, and in a gathering trip at Mine C, 6. The figures are presented as illustrative of methods used without attempting to present or recommend a general formula

Table I—Number of Cars and Other Data Bearing on Haulage at Twelve Mines

Mine	HL	YT	AS	TP	OW	SP	DS	RZ	GH	TS	RM	DI
Number of mine cars...	1,800	375	400		340	500	561	600	576	500	603	
Tipple capacity, tons...	8,250	1,250	2,000	2,500	4,000	4,000	3,000	5,000		5,000	3,000	3,000
	(2 mines)											
Storage.....	A day's output	Trestle open storage	Storage plant	None	750 ton bin	None	460 tons	1,000 tons	None	None	Surplus mine cars	400 tons in bins
Main line locomotives (all trolley).....	13-ton		13-ton	13-ton	13-ton	10-ton 8 ton T. cable from rooms	13-ton	13-ton	13-ton	13-ton	13-ton	15-ton
Gathering locomotives	{ 13-ton T. } { 6-ton B } Mules		6-ton T.	6-ton T.	6-ton T.	{ 10-ton 8 ton T. cable from rooms } 44	Mule	8-ton T.	6-ton T.	Mule	6-ton B	6-ton B.

Table III—Cars at Time of Visit

	Mine A	Mine B	Mine C
Number of cars owned.....	561	602	576
Number of tons produced.....	1,600	1,500	3,200
Number of miners working.....	275	168	257
Trips per car per day.....	2.23	1.32	1.92
Average main-line travel per loaded trip.....	9,000 ft.	5,500 ft.	4,500 ft.

or to indicate all of the variables that should be taken into account in an accurate analysis.

Mine A was operating with two main-line haulage locomotives of 13 tons capacity, one of which was helped by a relay haulage locomotive of 8 tons capacity, having a combined average haul of 9,000 ft. The cars, which were all small—2,700 lb. capacity—were all gathered by mules. These cars traveled from face to tipple and back again 2.23 times per day. The two haulage locomotives were running alternately and very evenly, and the figure of the management of a half trip of loads on the bottom parting was adequate as a haulage locomotive arriving at about that time with a loaded trip took away the trip of empties, so that the total cars at the bottom, both loads and empties, was $1\frac{1}{2}$ trips at all times.

At the relay parting the haulage locomotive dropped its empties and picked up its loads. Thus the management figure on one trip of cars for each haulage or relay locomotive was borne out by the facts, as each of the three had practically continuous traveling. On the arrival of the relay or haulage locomotive at the face parting the full trip on the parting was picked up and the empties left. Thus a figure of $1\frac{1}{2}$ trips per parting resulted in a theoretical assured supply of empties for the mules and loads for the motors.

No allowance for the cars for the mules was made, as it was assumed that the cars on the parting and allowance for one car continually at every other miner's place would cover those actually in transit behind the mules. The above method of figuring cars for the mine under consideration resulted in continuous delivery of coal to the tipple, which was the aim of the officials, and from their viewpoint the method of figuring was therefore correct.

In spite of that, however, both the foreman and the miners were complaining of an insufficiency of cars, and an insufficiency from the miner's standpoint there undoubtedly was, as the plan called for a car at his place only half the time he was in the mine. This is a case, however, of too many men for the mine capacity rather than an insufficiency of mine cars. Though the distance of the main haul was comparatively long (9,000 ft.) and the gathering was done by mules, the average use or turn of the cars per day of $2\frac{1}{4}$ was among the highest noted at any of the mines visited.

HERE FOUR TRIPS WERE ALLOWED FOR BOTTOM

Mine B was operating with three main-line haulage locomotives of 13 tons capacity, and their average length of haul was 5,500 ft. The allowance for a combined loaded- and empty-car supply at the shaft bottom of four trips as compared with only $1\frac{1}{2}$ in Mine A is due to the fact that the arrival and departure of the locomotives were very irregular, and the officials apparently deemed it necessary to plan on such a large supply as an insurance against lost hoisting production caused by poorly dispatched haulage.

The reason that two trips are figured for each haulage locomotive in this mine is that they planned one

trip as being hauled and the other trip waiting to be picked up at the partings. As a result the figure of $1\frac{1}{2}$ trips supply for each parting represents merely the working surplus there. In this mine the cars per loader were estimated at only one-third. If such a plan were actually operated when the mine was running at full capacity it would result in the miners waiting about 50 per cent of their time for cars. The turn of 1.32 cars per day at this mine for a 5,500-ft. haul was among the lowest noted and was in a large part due to the fact that the mine was not operating at over 50 per cent of its capacity.

Mine C was operating with four main-line haulage locomotives of 13 tons capacity traveling an average distance of 4,500 ft. Four trips of loads and empties were estimated as being always at the bottom because in Mine C, as at Mine B, the trips arrived at irregular intervals. The allowance of one trip for each haulage locomotive and $1\frac{1}{2}$ trips for each parting is in line with the theory followed in Mine A, that a trip should be figured for each main-line locomotive and something more, that a trip should be awaiting its arrival at the parting.

The allowance of two trips to each gathering locomotive is in addition to anything figured in the previous two cases and merely had the effect of increasing the cars allotted per man, which is one-half, as in Mine A. Here, however, the men worked in pairs, so that the theoretical effect was to keep a car continuously at each loading place, which represents the ideal condition from the miner's point of view. Practically, however, this condition did not prevail, as not only were the miners here as elsewhere waiting for cars but the tipple was idle 47 minutes in addition to incidental delays in an eight-hour day due to non-receipt of cars at the shaft bottom.

In none of the cases noted was definite allowance made for storage of coal in mine cars overnight to even up a part of the daily irregularity in the car supply. This is a point which is recognized by many mine managers as worthy of practical consideration.

CAR EXCESS WILL NOT SOLVE HAULAGE PROBLEM

This illustration is only one more link in the chain of evidence accumulated in the study of the mines outlined in the report, tending to show that, even in cases where a concrete plan exists for determining the proper number of pit cars for a mine operation, and this plan is liberal in comparison with the standards of similar mines, an adequacy of mine cars is not *per se* a solution of the problem of either continuous tipple operation or the elimination of lost time to the miner.

Planning and dispatching of the haulage not only will go further toward eliminating both, than the purchase of additional cars, but probably in many cases it will make possible a reduction in the number of mine cars in use. Furthermore, it will permit more accurate determination of the minimum capital outlay for the mine cars that will give satisfactory service.

A REPORT has just been issued by the U. S. Geological Survey on the Twentymile Park district of the Yampa coal field, in Routt and Moffat counties, northwestern Colorado. The Twentymile Park district includes only the southeastern part of this great field, but that is now its most important part, as it contains all the commercial mines that have been developed in the field.

Case of Opponents of 1921 Agreement In British Coal Mines

Unfair, They Say, to Make High-Cost Mines Pay Higher Wage Because Low-Cost Operations Earn Profit—Complicated Adjustments Required—Unwarranted Assumptions Enter

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

IN LAST week's article of this series this statement was made in connection with the discussion of the British coal agreement of 1921: "In those cases where the proceeds have been sufficient to meet the standard wages, other costs and standard profits, but insufficient to pay the mine workers the minimum wage, the operators have had to surrender the whole of their standard profits and are not allowed to carry forward against future income any such deficiency in their standard profits." This assertion has been questioned in view of the fact that it is provided in the text of the agreement that "if in any period the ascertained proceeds, after the deductions of costs other than wages and the cost of the standard wages, prove to have been insufficient to meet the standard profits, the deficiency shall be carried forward as a first charge to be met out of any surplus in subsequent periods."

A subsequent ruling on that provision, however, makes it inoperative. The provision is quite similar to agreements that have been reached in this country under which work is to continue until a decision is reached as to wage rates, whereupon it is to be retroactive. The plan is carried through if the decision provides an increase of wages but would obviously be inoperative should a decrease be ordered. No one would expect the miners to return any wages already paid.

It is generally agreed that one of the main objectives of the agreement would be lost were deficits allowed to hang over the more profitable periods. One of the main purposes of the arrangement is to stimulate productivity. A major need of the British situation is to increase the output per man. The only way this can be accomplished is to keep free of encumbrance the possibility of an increased wage at those times when the profit can be pushed to higher levels.

PROGRESSIVE ELEMENT FAVORS PROFIT SHARING

So much has been said in this series of articles in favor of the profit-sharing arrangement that the impression may have been given that there is no great amount of objection to it. Unfortunately there is another side of the picture. It can be said that the overwhelming majority of the forward-looking men in the British industry have great faith in the agreement and are prepared to stand by it. It is only fair, however, that some of the views of those contrarily minded should be set forth.

The agreement, some contend, is very unfair to the high-cost mine. The high-cost mines in a district are called upon to pay a higher wage because the low-cost mines have earned profits. The production of the high-cost mines is essential to the prosperity of the country. Under the agreement, it is predicted, the high-cost mines gradually will be eliminated, leaving in operation only the best situated properties. This would mean

great loss of production and restriction in employment.

There also is objection to the singling out of coal-mine labor and its removal from the effect of the general laws which apply to labor in comparable industries. It is contended by able men that labor must be considered as a whole. Any effort, they believe, to remove one class of labor and set it apart so that general economic principles are regulated in their application to the one group, constitutes a fundamental error which is certain to wreck the coal agreement in time.

Formerly wage advances were calculated in percentages. Under the agreement there is a change to a flat rate. This complicates greatly the maze of adjustments which have to be made under the agreement. One criticism is to the effect that the agreement appears to settle everything, but in fact it has settled nothing and has brought about dangerous confusion in a basic and highly essential industry.

OWNERS OBLIGATED TO HAPHAZARD SCHEME

As one critic puts it, "The coal owners are under obligation to pay certain wages determined by the haphazard amount of wages found to be payable at a certain date, plus, under certain circumstances, another arbitrary amount. Wages are to be determined at a certain figure quite irrespective of the circumstances which may prevail at the time when they have to be paid. The men working in a particular district are to be paid not what the labor of such men is worth in the country at large but such additional sum as may have been found due to them, long after the service has been rendered, after a complicated set of returns has been obtained from their employers and after a yet more complicated set of calculations, based on further assumptions." Even the assumptions are regarded as unwarrantable.

The uniform plan set up for accounting purposes, and which applies to the whole United Kingdom, makes for a series of inequities in certain districts, it is asserted. It is apparent that great difficulties surround the determination of just what constitutes profit in the production of coal. It is very difficult to lay down nationwide rules which do exact justice to every miner. One of the main causes of disagreement between the operators and the mine workers has been in regard to capital expenditures. It is apparent that improvements of a very substantial nature might be justified at a mine with large reserves of unmined coal. It is said that the men object to many expenditures which are essential to the business-like handling of the property. There is a natural tendency among the men to have for immediate division a larger proportion of the income than is justifiable. They are not inclined to take into account the fact that an improvement today will mean increased profits at a subsequent period.

Operators Open Anthracite Economy Show

IN ORDER to show how, by the use of proper heating appliances, the smaller and cheaper sizes of anthracite may be burned in household plants, the General Committee of Anthracite Operators in conjunction with manufacturers of heating appliances, has opened the Coal Economy Show at 1017 Chestnut Street, Philadelphia. The main floor, shown in the lower right picture, is given over to appliances and an information booth where fuel experts are in attendance to answer questions. On the main floor, shown in the picture on the lower left, there is a mine car of run-of-mine anthracite. Beside it is a series of seven bins holding the various prepared sizes from egg to barley, thus illustrating the difference between coal as it is mined and as the public gets it. The upper right picture shows a portion of the mezzanine where there is an exhibit of photographs showing various mine operations—breakers, machinery, pumps, maps, houses, schools, etc. There also are placards giving statistics and information

about the industry—models of a breaker, a jig and a mine barrier. At the upper left is a display window.

There is an auditorium where illustrated lectures on coal and mining are given twice daily and where a 2-reel movie will be shown twice a day. Special evening sessions are to be held for associations of architects, builders, plumbers and steamfitters, contractors, high school and college students.

It is planned to open other similar shows in Washington, Boston, and New York.

Among the exhibitors represented are the Molby Boiler Co., Lansdale, Pa.; Abram Cox Stove Co., Philadelphia; W. P. Mackenzie Co., Philadelphia; Philadelphia Steam Heating Co., Philadelphia (Oxykol system); Standard Heater Co. (Spencer heater), Williamsport, Pa.; Keystone Supply & Mfg. Co. (distributors Newport automatic feed heater), Philadelphia; Burn-Buck Co., Philadelphia; Culm-Burn Equipment Co., Inc., Philadelphia, and Domestic Stoker Co. (The Electric Furnace Man).

News of the Industry

Tri-State Meeting at Cleveland Jan. 4 To Begin Work on New Bituminous Scale

Ohio-Indiana-Illinois Joint Conference Issues Formal Call Dec. 21
for Parley—Actual Progress Unlikely Until After
Union Convention, Jan. 22

Negotiation of a new wage agreement affecting mine workers in the bituminous coal mines, to replace the present agreement, which expires March 31, will begin in Cleveland, Ohio, Jan. 4, when a joint meeting of union officials and operators of Ohio, Indiana and Illinois will be held. The call was issued Dec. 21 and was signed by Michael Gallagher, of Cleveland, chairman of the Joint Interstate Conference of Ohio, Indiana and Illinois, and John L. Lewis, president of the United Mine Workers of America.

S. H. Robbins and W. H. Haskins will represent the Ohio operators at the conference, P. H. Penna and M. L. Gould the operators of Indiana, and Rice Miller and H. E. Perry those of Illinois.

Ohio miners will be represented by Lee Hall and G. W. Savage; Indiana miners by John Hessler and William Mitch; Illinois miners by Frank Farrington and Harry Fishwick. Officers of the joint conference besides Chairman Gallagher are: William Green, secretary, and W. L. Robinson, assistant secretary.

Besides President Lewis and Secretary-Treasurer William Green of the miners' union, Vice President Philip Murray may participate.

The call for the meeting was as follows:

"The joint conference of miners and operators, of the States of Ohio, Indiana and Illinois in session in New York City on Jan. 24, 1923, adopted a resolution providing that the chairman of the joint conference and the president of the United Mine Workers of America should designate the time and place for the meeting of the joint sub-committee, signatories to the existing contract; the sub-committee to name the time and place for the formal assembling of the joint interstate conference, to consider the making of a new wage agreement.

"Pursuant to that authorization, the undersigned advise that the members of the joint sub-committee signatories to the existing contract will assemble in Cleveland, Ohio, on Friday, Jan. 4, 1924, at the Hotel Cleveland, at 11 o'clock a.m. It is hoped that all members of the sub-committee or their delegated representatives will attend this conference."

It is doubtful whether the real nego-

tiations will take place before the convention of the United Mine Workers in Indianapolis, Jan. 22, when the miners are expected to formulate their demands and instruct their officers.

To Force Employers to Carry Insurance on Workers

The State Workmen's Compensation Board of Pennsylvania has taken away from the State Department of Labor and Industry the enforcement of the state compensation law in so far as it relates to the mandatory injunction upon employers to carry insurance for their employees. The enforcement of this provision has been in the hands of the department for two years, the law providing that employers who do not obtain compensation insurance shall be fined \$1 a day for each employee. During this period, it was said at a recent meeting of the compensation referees at Harrisburg, not a single prosecution has been brought by the department and no fines have been imposed.

William C. Fisher, actuary of the department, who has had charge of the enforcement of the law's provision, said the State Compensation Board had refused to bring prosecutions. Since August thirty employers a month have been insured, he said, and he explained he had investigated 25,000 cases of employers who were not carrying insurance. T. Henry Walnut, chairman of the Workmen's Compensation Board, who recently pointed out that 80,000 of the 200,000 employers of Pennsylvania carry no compensation insurance, said the board will see that the law is enforced and that notice will be served upon all delinquents at once and they will be fined if they do not comply with the law within thirty days.

Royal Meeker, Secretary of Labor and Industry, has forwarded letters to all insurance companies writing compensation insurance in Pennsylvania and to self-insuring employers, asking them to furnish his department with more detailed information regarding causes of industrial accidents. An examination of the accident reports filed with the department, he said, shows that in a large number of cases the questions asked are incompletely answered "and in fact in some instances no answer is given."

Governors Receive Draft of Pinchot Hard-Coal Bill

Gifford Pinchot, Governor of Pennsylvania, sent copies of his proposed bill to regulate the anthracite industry, Dec. 18, to the governors of anthracite-consuming states, in accordance with instructions contained in a motion passed at the conference, in Harrisburg, Dec. 13. In a letter accompanying the draft of the measure, as well as a brief upon the sources of the bill, Governor Pinchot asks that criticisms or suggestions by the state executives be sent not later than Dec. 31.

Work upon the compact to be adopted by the states will be pushed as rapidly as possible, Mr. Pinchot stated, and invited suggestions concerning its form or contents. "The proposed compact between the states," the Pennsylvania executive wrote, "offers a practical way to reduce prices to the consumers; there can be no dispute as to its legality, and it offers, as no other method can, a uniform and unbroken system of control along the whole line from the mouth of the mine to the consumer's bin.

Portland Cement Output Off in November

Production of portland cement during November, 1923, according to a report by the U. S. Geological Survey, based partly on estimates, totaled 12,603,000 barrels, compared with 11,349,000 barrels in the corresponding month of 1922 and 13,350,000 barrels in October, 1923. Shipments for the month were 10,251,000 barrels, compared with 10,167,000 barrels in November, 1922, and 14,285,000 barrels in October, 1923. Stocks at the end of November amounted to 6,964,000 barrels, compared with 5,320,000 at the close of November, 1922, and 4,612,000 barrels at the end of October, 1923.

C. & I. R.R. Asks Extension

For the announced purpose of opening up for development 75,000,000 tons of bituminous coal, the Cambria & Indiana R.R. has asked the Interstate Commerce Commission for authority to construct and operate an extension of its line in Cambria County, Pennsylvania. The extension is to proceed from a point where the Monroe Coal Co.'s line intersects the company's main line at Revloc. The terminus of the extension is to be at Wilmore Road, near the bridge crossing the north branch of Little Conemaugh River. The length of the extension is to be 5.08 miles.

Says Coal Mining Needs More Engineers; Best Qualified to Handle Labor

Though Lawyer and Engineer Stand Together, It Is the Latter Who Looks Forward, Says Dr. Smith—Discusses Four Phases of Waste and Their Cure

Discussions of coal problems, Dr. George Otis Smith, the Director of the U. S. Geological Survey, pointed out in the course of remarks before the Washington section of the American Institute of Mining and Metallurgical Engineers, reveal the positions of the lawyer and the engineer. "They are standing together," said Dr. Smith, "but they are back to back—the engineer looking forward and the lawyer looking backward."

Dr. Smith presented four phases of the coal question, which formed the basis of a general discussion among those in attendance. These points were:

(1) Waste of resource—better mining; better utilization; effect of price.

(2) Waste of labor—short year and overmanning; larger use of machinery; mine management; union limitation of output; co-operative spirit.

(3) Waste of capital—overdevelopment; idle plants; limits on new development; waste through competition; combinations.

(4) Waste of transportation—the industry's bad load factor; seasonal peaks; long haul; unneeded fields.

Dr. Smith made a plea for the use of more engineers in the coal-mining industry and their utilization in connection with labor relationships. The engineer, he pointed out, has come up in a part of the work which has placed him in close personal contact with the mine worker. As a result, he knows him in a personal way and frequently is better qualified to deal with labor problems than is the mine manager, who often rises to his position through the accounting department. He believes that labor can be brought to a much higher plane of efficiency and expressed the hope that the matter of individual productivity would find a part in the program of labor leaders. He mentioned that he had heard long discourses by labor leaders but had been impressed by their failure to mention the need of increased efficiency. He expressed decided disapproval of any plan which has as its object the limitation of individual output.

Dr. Smith declared that waste is an outstanding ill in coal. There is waste from the face to the stack, he said. There is waste in man power and each time the industrial cycle goes round, these wastes seem to increase, he asserted. If there were better mining and better utilization, the equivalent of 100,000,000 tons of coal might be saved every year. He characterized as deplorable a rate situation which in one year resulted in the transportation of 5,000,000 tons of coal to the lakes from

Southern fields which displaced nearby coal equally suitable for the movement. During a six months' period that useless haul represented a loss of 1,500,000 ton-miles.

Major Starr, of the Chamber of Commerce of the United States, deplored the attitude of the United Mine Workers toward the use of machinery in mines. Where machinery is used, he declared, it is necessary to pay the men the full amount of the saving made. He cited the great economies and improvements which had been made possible in the non-union mines through maximum use of labor-saving machinery. He mentioned one mine in which there are no mules and no picks. Coal is produced there just like shredded wheat, he said—"not touched by human hands."

O. P. Hood, chief mechanical engineer of the Bureau of Mines, declared that there are many inheritances of

the days of dollar coal which must be overcome. Management must pay more attention to the boiler room, he pointed out, under the changed conditions of higher fuel costs. He expressed the opinion that there is too much imitation in engineering. One engineer will get a desirable result and others will follow like sheep. Mechanical equipment for the handling of coal must be suited to the individual problem, rather than that met with in another plant. He urged more study of the combustion problem.

Walter Trent called attention to the fact that at least 90 per cent of the values in ore are recovered at metal mines. Each ton of coal, he said, contains \$14.50 of value, but the recovery is less than 20 per cent.

H. Foster Bain, director of the Bureau of Mines, made the point that control over development would do more than any other single thing to solve the difficulties of the coal industry, but that such a policy would be entirely contrary to the principles which the American people always have supported. Public opinion would not submit to any drastic step looking to limitation of the opening of new mines. He pointed out the tendency for acquaintanceships now to run in business lines. People formerly knew each other because of their geographical proximity. Now like activities seem to control personal relationships, he said. He prescribed constant flow of facts as one of the needs of the industry.

Praise for Oddie's Bill

Introduction of Senator Oddie's Department of Mines bill is bringing much commendation of the measure. H. Foster Bain, director of the Bureau of Mines, in a letter to the Nevada Senator, says:

"I have no hesitation, as a mining man, in expressing my personal conviction that if such a department can be created it will be of the greatest possible service to the country, as a whole, as it will to the particular industries in which you and I are especially interested. It will be of great benefit to the mining industry, and accordingly to the public interest if, so far as is possible, the various functions of the federal government that relate to mines and mining can be brought together."

Dr. George Otis Smith, director of the U. S. Geological Survey, says: "All who are interested in federal legislation which recognizes and promotes the mineral industry are gratified by the consideration of such a measure as the one you have introduced."

F. F. Sharpless, secretary of the American Institute of Mining and Metallurgical Engineers, wrote: "Our directors are deeply appreciative of your many efforts in behalf of the mining industry. They feel that in you they have a staunch and loyal advocate for every matter of merit in which the mining industry is concerned."

I. C. C. Denies Higher Rate From Tennessee Mines

Proposed increases in the rate on coal from points on the Tennessee R.R. to Louisville, Cincinnati and other points are not justified, in the opinion of the Interstate Commerce Commission. The case was brought by the Cincinnati, New Orleans & Texas Pacific and the Tennessee R.R. in an effort to increase rates to Louisville and Cincinnati by 9c. and 10c. more than the rates from all other points of origin in the group embracing the mines on the Tennessee. A 15c. increase was proposed to points in other states in the Middle West. The proposed increases were opposed successfully by the Southern Appalachian Coal Operators Association.

In its opinion, the commission holds that the proposed rates would disrupt the general rate situation from certain of the groups involved and would give undue preference to mines on and shippers from the Oneida & Western and other short lines in the same general territory. "If the Tennessee is unable to exist under reasonable rates and just, reasonable and equitable divisions of joint rates," says the opinion, "its connections cannot be called upon to bear any additional part of its expenses. The producers of coal and lumber along its line are interested more than anyone else in its maintenance and continued operation."

Illinois Sees Coal Strike April 1, but It May Be a Short One

Long Fight Likely Only If Miners Insist Upon Wage Increase—Operators' Association Favors Four-State Parley and Wage Cuts—
"Wages O. K.," Some Say

Illinois is looking toward April 1. Now that the Illinois Operators Association has gone on record as favoring participation in four-state negotiation by Illinois, Indiana, Ohio and—faint hope—western Pennsylvania, and a reduction in miners' wages, the question, will there be a strike? is much at the fore. The general sentiment throughout the state is that there certainly will be a strike. It may be short if the miners will be willing to renew the present wage contract, or it may be long if they will not. But it will be difficult to avoid a shutdown.

The action of the association, taken in Chicago Dec. 20, gives form to one body of opinion in Illinois. But not every important operator favors a drive to reduce wages, necessary though that may be to many companies. Some declare there is no use trying it and that they will not fight for such a thing. Therein lies the chance for a strike of only short duration. It is calculated that the mental attitude of mine labor will make it difficult if not impossible for President John Lewis, to sign a continuance of the present scale before April 1. Hence the necessity of a shutdown—unless government pressure upsets negotiations between operators and miners.

However, the Illinois operators who will not fight for wage cuts will fight against wage increases. They say so flatly. Therein lies the chance for a long strike. They recognize that one of the worst things for the industry would be a long strike. It would revive a lot of wildcat operating that is now either dead or dying and which, they think, ought to be permanently trimmed off the body of the industry. But even that constant menace is not enough to feaze them. The suggestion for wage increases makes them see red and battle light appears in their eyes.

Of course it is generally believed that the 10-per cent increase which is noised abroad in labor circles as one of the probable demands of the union is merely "swap talk." It is to be traded by the miners for operator proposals, such as the well-worn ones about discontinuance of the check-off, division of the country into small districts for wage-making and the like.

There will be some new proposals by the operators this time, however. One of them concerns a wage scale for underground loading-machine operation. At present there is no scale although a good many machines are now working in such unionized regions as western Kentucky, Indiana and Illinois. Western Kentucky's general wage contract runs another year, but that field looks on with interest while the Middle West maneuvers for a recognized

loader scale. Quiet negotiations between operators and miners in Indiana thus far have gained little ground. Operators insist upon a day scale and miners upon tonnage rates, and there they split. However, there have been some faint indications that the parties to the case are really closer together than they seem, for many miners are seeing the light.

This and other questions will be taken into the coming conference by Midwest operators, and earnest efforts will be made to get something done about them. But the sentiment generally is that the whole problem is too complicated to be wound up by April 1.

Strike Called Off in Maryland Cost Union \$734,000

In the *United Mine Workers Journal* of Dec. 1 is a formal statement, informative in a general way, of the decisions of the Policy Committee that John L. Lewis foregathered in Indianapolis for several weeks in November. The miners' organization spent nearly three quarters of a million dollars in supporting the 20 months Maryland strike beginning April 1, 1922. Nothing was said about West Virginia. The statement follows in full:

"After being in session more than a week, the International Executive Board of the United Mine Workers of America transacted an enormous amount of business, adjourning Nov. 20. A greater part of the session was devoted to reviewing the work accomplished and now under way by the organization in the various districts within the confines of the jurisdiction.

"The board, after going over the matter of the revocation of the charter of District 26, Nova Scotia, in July this year, approved the action of the International officials and authorized a continuance of the provisional district under the direction of the International union.

"The matter of the strike in Maryland, District 16, which has been on since April 1, 1922, was discussed and the board made arrangements for the termination of the strike. During the period of the strike financial relief to the members of the district was advanced in the total of \$734,000, it was announced.

"The International board together with the officers of the International union were authorized to continue their efforts to obtain action from the Interstate Commerce Commission relative to the matter of "assigned-car" practice as indulged in by railroads, public utilities and large consumers of coal.

"The board gave considerable atten-

tion to the program of litigation in which the organization is now involved, due to various damage suits, injunctions and other legal processes brought against the organization in the various districts. The matter of litigation in Alabama was especially gone into.

"The organization is facing a number of damage suits. The board was particularly interested in the victory won by the union in the second trial of the Coronado case. It is believed that the winning of this case by the miners will have set a strong precedent as to the final outcome of several similar suits now pending against the union.

"The board had a large number of appeals and grievances from the various districts, and these were taken up for decision. The finances of the organization were reviewed and found to be satisfactory. There will be no further meeting of the board until after the convention in January."

"And Satan Also Came"

When Governors Pinchot, of Pennsylvania, and Silzer, of New Jersey, occupied places at opposite sides of the toastmaster at the annual dinner of the New Jersey Society of Pennsylvania, Dec. 18, in Philadelphia, 300 members of the society were prepared to see the fur fly—and they were not disappointed.

"I thought I would say something about coal tonight," said Mr. Pinchot, "but you will realize the position a fellow is in who has not yet been able to determine whether he was successful in getting coal in the homes of the people or was merely responsible for raising the price.

"I called a coal conference of Governors some time ago with the idea of doing something to decrease the price. Not many Governors responded, but Silzer did. I wonder if it would be unfair in this connection to recall an old quotation which runs, 'And Satan also came.' At any rate, Governor Silzer was there. I tried to convince him that New Jersey might also be persuaded to take her share in the responsibility of reducing the price of coal. But he couldn't see it. He wanted Pennsylvania to do it all. But I beat him to it by calling another conference, and he didn't come. But the Governors who did decided that the other states should help, including New Jersey, and so, you see, he's in the game anyway."

"I do not object to the Governor's quotation, 'Satan also came,'" said Governor Silzer in reply to Mr. Pinchot, "because I have a distinct impression that on the occasion he refers to the Governor of New Jersey gave the Governor of Pennsylvania a little bit of hell."

Oddie Studies Coal Commission Report; To Base Legislation on Findings

Constructive Bill to Promote Better Service by the Industry Expected—
Co-operation with Hoover Likely on Commercial Phases—
Pinchot Conferees Soon to Press for Federal Action

BY PAUL WOOTON

Washington Correspondent, *Coal Age*.

An intensive study of the report of the Harding Coal Commission is being made by Senator Oddie, of Nevada, chairman of the Committee on Mines and Mining, with the idea of translating into legislation such of the recommendations as may meet his approval. He has not proceeded far enough with the study to determine just the form this legislation will take. It is entirely probable that it will incorporate certain suggestions which have been made since the report of the Coal Commission was issued.

It is a relief to many who are deeply interested in the best interests of the coal industry to know that the legislation to grow out of the Coal Commission's report is to be handled by a legislator who is entirely constructive in his tendencies. For that reason it is safe to assume that the administration measure will not come out as full of teeth as a corn shredder, vesting the Federal Trade Commission with powers to conduct a new program of regulation of the punitive type. Senator Oddie is confidently expected to bring out legislation which will seek to foster and promote the coal industry along the lines that will enable it to furnish better service to the public.

Bills that have been introduced at this session have been designed to lambaste profiteers or deal with first-aid matters such as penalizing shipments of dirty coal or embargoing exports.

PRODUCTION CRUX OF COAL PROBLEM

Senator Oddie feels that since the whole coal question revolves around its production, it really constitutes a matter clearly within the jurisdiction of the Committee on Mines and Mining. The parliamentary officials of the Senate have taken the same viewpoint and Senator Oddie believes his committee is in a better position than any other to handle such fundamental coal legislation as the country may need. On the commercial phases of the problem, it may be accured that Senator Oddie will work in close co-operation with Herbert Hoover, Secretary of Commerce. In fact he already is co-operating in a major way with Secretary Hoover on various problems having a bearing on metal mining.

Legislation now is imminent from another quarter. It is expected that the Governors who participated in the Pinchot conferences soon will have agreed on the draft of a bill which they will put forward. There is some surprise in Washington that the diverse interests represented by the consuming states should have come to an agree-

ment so readily. While the effort is going forward to obtain the interstate pact, it is clear that the principal hope of the Pinchot conference is in federal action. If the Governors of these states represent the trend of public sentiment, it will mean strong pressure for federal action. Enough is known of the Pinchot draft to indicate that it is another suggested code of penal rules. For that reason there is a feeling that it is particularly timely that Senator Oddie should be considering the bringing out of legislation of a more constructive type.

Bureau of Mines Reports on Work of Past Year

Practically 100,000 miners have been trained by the Bureau of Mines in mine-rescue and first-aid methods since the establishment of the bureau in 1910, states Director H. Foster Bain, in his annual report to the Secretary of the Interior for the fiscal year 1922-23. Whereas in 1910 the bureau trained 734 men, during the past year 14,941 men received the training, which was conducted in 35 states and Alaska.

Two effective methods for preventing the spread through a coal mine of a minor initial explosion have been demonstrated by the bureau at its experimental mine near Pittsburgh, where more than 500 experimental explosions have been produced and in which the explosibility of coal dusts from all parts of the country has been studied. The first method is to wet the dust so thoroughly that no dry dust remains in the mine. The second is to dilute the coal dust with shale dust, limestone dust, or other non-inflammable dust so that flame will not pass from point to point.

The widespread attention given to the fatalities from explosions has resulted in the common supposition that gas and coal-dust explosions form the main hazards of mining, but the bureau finds that if the deaths from falls of roof and coal could be eliminated, the number of miners killed would be cut approximately in half. The deaths from roof falls aggregated 900 during 1922. The fact that this number is less than the total during several preceding years is due to thousands of men having been idle for several months during the bituminous-coal strike.

The larger part of the responsibility for decreasing this class of accidents may fairly be placed on the miners themselves, states Director Bain. Most of the falls occur at the working places and the miners there are better able

to observe the conditions under which they work and to tell when the roof should be taken down or additional props put up than is anyone else.

For the 11-year period that ended with 1922, 47.84 per cent of all fatalities were due to falls of roof and coal, 16.85 per cent were caused by mine cars and locomotives, 11.25 per cent by gas and coal-dust explosions, 6.04 per cent by explosives, and 3.47 per cent by electricity. During this period 25,975 men were killed in coal mines. Approximately 90 per cent of all the deaths occurred underground, 2.29 per cent were from shaft accidents, and the remainder, 7.59 per cent, occurred on the surface.

Director Bain cites the need for an intensified safety campaign among miners, operators and inspectors to maintain diligence in observing the precautions which will lead to the prevention of accidents. This includes a wider dissemination of the knowledge already acquired by the Bureau of Mines and the agencies which have been co-operating with it.

An intensive study of the electrical hazards in coal mining and of those following the more extensive use of machinery underground should be made.

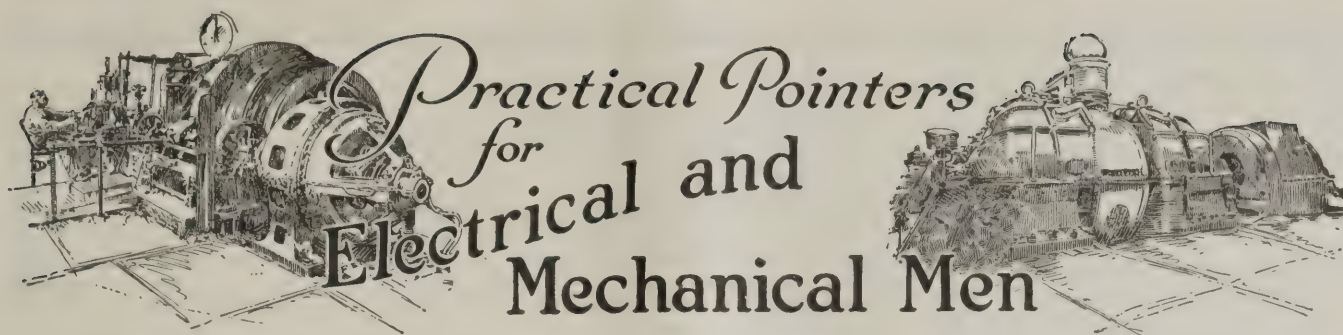

Concentrated effort should be made to reduce the number of deaths from falls of roof and coal and from mine transportation, both of which call for further investigative work and renewed alertness by miners and operators.

Coal is now being mined on public lands under lease in Colorado, Montana, New Mexico, North Dakota, Utah, Washington and Wyoming. Prospecting permits have been issued covering areas in these states and in Alabama, Arkansas, Arizona, California, Idaho, Nevada, Oregon, and South Dakota.

A vertical oven, designed to produce a lignite char as a stable fuel for domestic and power purposes, was built and operated in co-operation with the University of North Dakota. Some of the char was shipped to the Pittsburgh station of the Bureau of Mines, where grates suitable for burning it in an ordinary cookstove were designed which proved successful in laboratory tests. The lignite char proved an admirable fuel.

Improved methods and a portable instrument were devised for determining quickly the severity of cases of carbon monoxide poisoning and the carbon monoxide content of mine atmospheres. Important economies were effected in fuel consumption and in operating practice at various plants making refractory wares and at brick kilns.

HENRY WALKER, a mining engineer who is serving as deputy chief inspector of Mines for Great Britain, will visit this country in February. Arrangements are being made by George S. Rice, chief mining engineer of the Bureau of Mines, which will make possible first-hand observations as to safety methods employed in American mines.

Method of Suspending Feeder Cables to Many Levels

Up until about ten years ago power was supplied to electrical equipment in the anthracite mines by means of cables suspended in the airshaft, which usually is just alongside of the regular hoisting way. This served the purpose rather well for a time, but as the equipment increased and an entire operation

depended upon the feed lines hanging in the shaft, frequent stops due to the burning of the wires in wet shafts compelled officials to look around for some other method.

The old oak-pin side bracket, nailed to the shaft bunting, and fitted with a deep-grooved glass insulator to which the 4/0 weatherproof wire was fastened by a copper tie wire, soon gave way to the armored cable, supported only at the top of the shaft and allowed to hang free alongside of pipes and other obstructions in the shaft. Following this came the boreholes, generally about 12 in. in diameter and protected from water by pipe cemented in on all sides. The usual procedure was to start this hole from the surface and drill down through probably a half dozen different veins. In this way the hole was in the solid at all points. After its completion it was tapped at all veins and sufficient of the pipe cut away to allow connections to inside feeders.

A sufficient length of cable to reach from the surface to the first vein and into a set of switches at that vein, is now dropped and anchored to supporting spools at the top of the hole. A set of copper busbars is then installed a foot or so away from the bottom of the hole at the first vein. One of these busbars takes the positive and the other the negative cable. A tap is taken from the negative busbar and run directly to the rail in the first vein or level. A second tap is taken from the positive busbar, thence to a switch of sufficient capacity to withstand the maximum current which will be demanded by the equipment in that vein, and out of this switch to the trolley wire.

A second cable of sufficient length to allow for anchorage at the first vein and running to the second vein is placed in a manner similar to the way it was handled in the first vein. This method is carried on at all levels, making it possible to disconnect any individual vein from the main cable in case of trouble with feed lines or trolley wires due to falling roof in the workings.

For a time after the adoption of the cemented-in pipe between the veins, the cables were installed without cutting at the various veins and were allowed to hang their entire length from the surface to the lowest vein to which power was being furnished. Taps were taken from the cables as they passed each vein, the positive cable leading to a

FIG. 2—SEPARATE CABLE TO EACH LEVEL

This arrangement requires a separate cable support for each section of cable, but repairs may be more readily made with a short piece of cable. Latest practice is along these lines.

section switch and the negative cable to the rail.

This was found to be an expensive way to install cables inasmuch as a grounded wire between the surface and the first vein generally resulted in the

FIG. 1—CONTINUOUS CABLE FROM SURFACE TO BOTTOM LEVEL

At each vein the cable is tapped. A disadvantage of this plan is that a break anywhere in the cable is likely to carry all the switching equipment of each lower vein with it as it drops.

cable burning off and causing it to drop to the foot of the hole, taking with it much of the switching equipment connected to it at the various veins. With the present scheme, however, it is possible for any one of the separate cable lengths between the veins to burn off and drop in the hole without destroying the rest of the system other than cutting off the supply to any vein below the affected cable. The repairs therefore consist only in dropping a short piece of cable, of the length required, between the two veins. In the first case, where the cable was in one piece from the top to the bottom, it was always necessary to drop new cables the entire length of the hole as well as to make new taps at all of the veins. Short lengths of cable, well anchored and installed in a perfectly dry hole, provided they are of sufficient cross-section to carry the maximum current, will last for years without giving trouble of any kind.

Scranton, Pa. M. S. BEDDOW.

Important Mechanical Details Of Locomotive Motor

Dust, sand, etc., when mixed with oil, have a grinding action on the bearings of locomotive motors, wearing away the bearing linings as well as the shaft or axle. As a result, various means have been taken to make these bearings dustproof and thus extend their life in service.

It is necessary to keep dirt, water, etc., out of the oil so that it will not be drawn into the bearing surface with the oil. This is done by having a tight cover over the oil and waste pockets, held in place by a spring. This cover should be lined with felt and should have a deep lip to prevent wheel wash, etc., from splashing in.

KEEP DUST CAP TIGHTLY FASTENED

The outer end of the commutator end armature bearing is ordinarily protected by a dust cap over the end of the shaft. This cap is made of sheet steel or malleable iron and is fastened to the housing or the bearing by bolts or screws, completely enclosing this end of the bearing. This dust cap should always be kept in place, as the position of the bearing with respect to the wheel flange is such as to permit the dirt, sand and wheel wash from the wheel flange to be thrown directly on this part of the motor.

The outer end of the pinion end bearing usually extends into the gear case and needs no further protection. The gear case fits over the armature bearing or an extension of the housing with a sufficiently close fit to keep the lubricant in the gear case and tends to keep dirt out of the bearing at this point. There is little possibility of dirt, etc., getting into the armature bearings from the inside of the motor, as the oil throwers on the shaft and oil catchers on the housings act as guards and give ample protection against the entrance of dirt.

Stress Importance of Bonding And Get Better Voltage

Until such time as those most concerned in keeping the electrical equipment in mines up to the minute realize that building of haulage tracks is just as important as the trolley wire, and is the return for whatever power is sent out by the trolley wire bonding will not be taken seriously. It is surprising what little attention is given to this important link in the chain power feeders.

Electrical men who give scrupulous attention to the installation and maintenance of trolley wire leave the other side of the circuit to a bonder who frequently is too young to know that he must do his work well if the locomotive which is to operate on a certain road after he is through bonding is to perform in a satisfactory manner. Channel pin bonds are sometimes installed in too hasty a manner, and quite frequently the channel pin, instead of being driven straight with the hole, in which case it will press in on all sides of the bond securely, will be allowed to cut into the wire and sever it almost in two. Hence a high-resistance joint is the result, and if two or three of these occur on a long, steep hill, power troubles can be looked for. It seems a foolish thing to insist on a well-kept trolley if the bonding is not also installed properly and kept in good condition.

IMPORTANCE OF THE BONDER

A bonder should be given to understand that his job is not merely a stepping stone to the higher position of electrician. He must first be a good bonder, else his chances for being a good electrician will not amount to much. Make him understand this, at the same time impressing on his mind just why he holds an important position. Explain to him just what the bonds he installs are doing and the damage they can do if not put in properly. Make him clean all holes in which the bond and channel pin are inserted, and insist that the pin shall be driven in straight and true, so that there will be no cutting away of part of the cross-section of the wire itself. Make him understand, also, why the pin should be driven all the way home, why this will result in preventing moisture from entering and destroying the fit of the hole, and finally, take him into your confidence and explain just why he must be a good bonder if he ever hopes for anything better.

It is remarkable how the efficiency of a mine will pick up once the bonding is put in proper shape. When a sudden complaint comes to the electrician that the power in a certain part of the mines has fallen off it usually will be found to be due to neglected bonding. An efficient bonder is worth his weight in gold to an electrical organization, and it is a surprising thing how much his work will improve when he is given to understand that what he does is of value and is appreciated as such by the whole organization.

ELECTRICAL INSPECTOR.

How the Maximum-Demand Indicator Operates

When the maximum demand register is part of the watt-hour meter mechanism, the meter, in addition to recording the amount of energy used, gives the maximum demand at which this energy has been used. The operation of the maximum demand indicator usually is by means of a pusher which at the beginning of a predetermined period of time advances the maximum-demand indicator hand over the scale. The speed at which this maximum-demand indicator can operate is a function of the speed of the meter disk.

At some predetermined time interval the forward motion of the pusher ceases and it is instantly withdrawn or reset to a point where it starts to travel again for the next time interval. The indicator hand is, however, left at the point on the demand scale to which it has been advanced by any previous operation of the pusher and it is not advanced until a higher maximum demand comes upon the line. Most meters are arranged to be manually reset by the meter reader or meter inspector.

The position of the maximum-demand indicator records the maximum demand which has occurred since the last time the meter was reset, providing the time intervals during which the pusher is moving are constant. This brings out an important point in connection with maximum-demand meters, and that is that the timing device be very accurate. In a newly designed meter this timing is accomplished by means of a synchronous motor which inherently operates at a definite speed; in fact its speed can change only with the frequency of the alternating-current supply, and since the frequency of the system is constant, the synchronous motor drive must be constant. This feature represents one of the latest developments in maximum-demand meters.

Banking Power-Plant Fires

The fire under the boiler should never be banked until it is quite certain that there is not going to be a demand for the use of this boiler for a few hours, as much of the coal burned during the banking is a loss and if the fire is prepared for banking just before a load comes on, much time is lost in getting the furnace back into favorable operation. While the fires are banked the stokers should be periodically moved to prevent the fire bed from becoming too porous or honeycombed.

The usual procedure in preparing and banking the fire during periods of low demand is this: (1) The forced draft is shut off; (2) the induced and forced draft fans are stopped; (3) the stokers are stopped; (4) the damper on the stack is closed to a degree just sufficient to clear the furnace of gases; (5) the feed water valve is closed.

Problems In Underground Management

Shaft Designed to Make Replacement of Buntons Easy and Avoid Wreckage

When a Cage Runs Wild the Buntons Catch It and Much Damage Is Done If They Are Torn Out—A Way to Minimize the Destruction

The main shaft of an important American mine has been lined with reinforced concrete from 1 ft. to 2 ft. thick on all sides, the concreting extending from the sump bottom to the surface, a total height of 150 ft. The sump is 12 ft. deep and the net opening of the shaft 11x15 ft., the concrete bottom resting on hard rock. The shaft lining continues upward, and where it passes through the coal strata, the walls are extended to a width of 24 ft. and are made 2 ft. thick with a suitable design to support the roof of the shaft bottom and to make it possible to load and unload rails or pipe on the bottom without lack of headroom or other similar difficulties.

In casting the concrete, a channel, or long, narrow recess 12 in. wide and 2 in. deep and extending the entire distance from the sump to the ground landing, was provided in the side walls for the reception of the buntons, which were placed after the concrete had set and the forms had been removed. The buntons are 10-in. iron beams the ends of which are provided with angles. On one end these angles are riveted and on the opposite end they are bolted. The bolted angles are designed so that they can be removed if necessary should an accident or other cause make replacements obligatory. By drifting the angles, the original tension always can be expected on buntons so installed.

CAN READILY INSERT NEW BOLT

For the reception of the guides a cast-iron chair provided with a T-slot was bolted to the web of the buntons. These castings are so arranged that a new bolt can be inserted readily, should it become necessary to do so. These castings or chairs not only support the guides but form for them a permanent base or line. The guide replacements go against the face of the chairs previously set to line and secured, and thus automatically they come truly to a plumb line with their faces in correct position.

The buntons were inserted in the slot and securely keyed with iron wedges to the proper tension. Then the entire channel was filled with a lean mixture of cement mortar, troweled

flush with the side walls of the shaft. Should it become necessary to remove any of the buntons, a pick will cut the lean mortar and expose the bolted angles, which can then be removed, allowing the buntun to drop out of the slot for removal. Should an accident occur in the shaft severe enough to dislodge the buntons, the lean mortar will yield to the strain and break away without serious damage to the buntun itself.

The concrete end walls are provided with T-slot castings set into the mixture at the time of casting and permit of bolt removal, and in general these castings resemble the chairs fastened to the buntun for the purpose of supporting the guide. In both cases these castings are set at 6-ft. intervals, providing anchorage for guides accordingly. The guides measure $5\frac{1}{2} \times 7\frac{1}{2}$ in. and are of pine throughout.

Close Propping and Small Falls Save Timber

BY R. W. LIGHTBURN
Gans, Pa.

Posting in the mines should be done according to system. For instance, if 4 ft. is the desirable distance between props in somewhat bad roof, props should be set 4 ft. apart and in line across the rib, that is, being drawn regardless of the roof being good or bad.

The miner may object to setting these posts, arguing that he can mine all the coal under the coming area of fall with less posts than he is asked to set. Perhaps he can, but there is another party at interest, the man who has to draw the posts. His safety depends on as few posts as possible being bent or broken under the pressure of the roof.

The purpose of the posts is to steady as far as possible that part of the roof over the area extracted and not yet caved. They must be sufficiently numerous to prevent the roof from becoming broken or cracked. They must retain in the roof its inherent strength. If too few are used the roof will be fractured and the posts will be under too heavy a burden. Should they break

down, not only will the posts be lost but also several tons of coal.

Falls should be kept within proper dimensions. The area allowed for a single fall should be about 16x24 ft. It will have about four rows of props and extend for a width equal to the combined width of room and pillar. Where the falls are kept to such a dimension the posts do not have to stand in place long and are not subjected to inordinate pressure and so can be used over and over again.

Only persons of experience should remove timber. Such a man will have an established method of removing difficult props. Some of the posts may have sunk into the cap-piece and to recover them extra posts must be set so that the man who is doing the work can be in the line of greatest safety and in the most favorable position for the recovery of posts.

If the bottom is hard and much slate has been thrown back among the posts so that it is difficult to get at the post bottom to loosen it, a slanting cut should be made in the post near the cap-piece with a sharp axe and on the outbye side of the post. A post puller should then be attached, and then with the exercise of a little force the post will come out.

I would advocate that the man who must recover timber be the man to place it. If a rib boss were given a section of suitable size he could do both satisfactorily.

To draw posts the timberman should have an axe with a hammer on one face. It should have a handle 4 ft. long. He also should have a punching post with a 6-ft. iron handle and fitted with a light pick-shaped head which can be stuck into a post that has been knocked down so that the post can be drawn to a point where it can be removed by hand. This punch post is useful in recovering crossbars. To get the best results specially designed tools for all purposes should be used.

Urge Early Coal Loading

Shippers of coal in northern West Virginia have been asked by railroad companies operating in that part of the state to load as much of their coal as possible during the first three days of the week, if it can be done without prejudicing the business of shippers. This request is made in order that the roads may be in a position to clean up business on Friday and Saturday of each week and is part of a program of increased economy in connection with the handling of traffic.

Discussion

How to Prevent Gas from Causing Explosions

BY GEORGE EDWARDS
Pikeville, Ky.

Recent mine explosions have awakened a new interest in the means of preventing such catastrophes. To handle a mine generating explosive gas is a job for a man who has been trained in the work as it were from the cradle up and should not be placed in the hands of any other. When considering a foreman's experience everything depends on where that experience was obtained, under what management he has worked and how long he was able to stay. Some companies are proud of the fact that they train their own men, and that is without question the best plan to adopt, but if they have been operating nongaseous mines and then encounter explosive gas, they should break that rule and go out of the organization for an experienced man to take charge of the job.

When gas is found, no matter how little, thorough plans should be made to provide for every eventuality and every opportunity should be taken to discourage disregard and indifference to small accumulations of gas. The tendency of the average boss who is not familiar with gas is to pretend to be wise and abundantly able to take care of the situation. Such men may be found lighting the gas for the fun of seeing it burn, until at last some man lights a trace, as he has often done before, and finds more gas than he expected and becomes to his surprise a badly burned man or something worse.

WISE FOREMAN PLAYS SAFE

The foreman who is familiar with gas will not allow the bosses or the workmen to do anything foolish, for he has learned that an ounce of prevention is worth a pound of cure and you will find him getting ample ventilation up to the working faces, which means that all stoppings and overcasts are well built and that no crosscuts are allowed to remain open but are promptly stopped with masonry stoppings.

Doors usually are necessary in the advanced workings, but the strictest kind of regulation should be enforced in having them built so that they will close automatically and everyone in the mine should be made understand that leaving a door open is a serious offense. The night shift usually is the hardest to control, and among the worst to leave doors open and damage other equipment are the undercutters and their helpers. The night foreman in a mine generating explosive gas should be thoroughly capable.

It is a good rule to have the firebosses register in, to insure that they are taking all the time necessary to

cover their section carefully. If this is done you will have no late starters, and if a fireboss should fail to report for duty, whoever is in charge will be able to make provision for his replacement. The firebosses should examine all doors and see that the ventilation is traveling in its proper courses both on Sundays and holidays.

Looking back over my experience with firebosses, I cannot forget that they often are young men who are just starting on their first responsible job, and for this reason they should be rigidly disciplined. I have found them in most cases familiar with the work they are supposed to do, but they fail in most instances because they are not willing to do the work as it should be done. A fireboss examining a mine with extensive pillar work has a hard job before him, especially in thin coal.

The foreman in charge should devote his entire time to the inside workings and he should be in constant command of all operations from beginning to end. The "sunshine foreman" should be eliminated from the gaseous mine.

Denies Undue Delay in Rescue Work at Hunt Mine Fire

In *Coal Age* of Nov. 15 there is a note with regard to the fire at the Hunt Mine, near Staunton, Ind., in the course of which there is an implied criticism of the delay of men from the Vincennes station of the Bureau of Mines reaching the fire. The facts are as below:

The notice of the fire reached the Vincennes station at 10 a.m. The foreman left at once for Staunton in a small truck belonging to the station and arrived at the mine, 80 miles distant, in two hours and thirty minutes. At the time the call came in some minor repairs were being made on the big truck, so that it was nearly 11 o'clock before it was ready to start. The first-aid miner driving it covered the 80 miles in 4 hours and 30 minutes, arriving at 3:30 p.m. This is good time for a large truck heavily loaded with equipment, and one designed to travel 20 miles an hour.

When the foreman arrived at 12:30 p.m., flames were pouring out from the mine and it would have been impossible to enter it even if apparatus had been at hand, but he helped the fire companies from Brazil and Terre Haute, who by that time had a fire engine pumping water from a pond a quarter of a mile distant and were throwing a good stream of water on the fire.

At 3:30 p.m., when the apparatus arrived, the fire was about extinguished. Word was sent down the slope to the foreman, who in company with Mike Scollard, former chief mine

inspector, and William Morwood, inspector for the Associated Companies, immediately came out and commenced to assemble the apparatus. This required about twenty-five minutes. Just as they completed this and started for the mine opening, word came out that the firemen had gone on into the mine without equipment and were bringing out a body. The foreman and the two men above mentioned then went into the mine and brought out the fourth and last body. The firemen who rushed into the mine without apparatus were, of course, running a great and probably unwarranted danger of being overcome by carbon monoxide, and in fact they were nearly overcome.

It can hardly be expected that the federal government will be able to maintain rescue and fire-fighting crews in such numbers as to permit their reaching each mine in less time than was taken in this case. In fact, the time might well have been longer, since it is the duty of the men of the mine safety service to devote the greater part of their time to training at the mines, and it is only by chance that they are actually at their headquarters at any given moment. When the Mine Safety Service was established it was more with a thought of demonstrating methods and training men than to relieving the industry of all of the work of first aid, rescue and fire fighting.

Whenever and wherever the men of the service are available they are instructed to proceed promptly to the scene of the disaster and to render any aid possible, but the major responsibility of meeting any emergencies must always rest on the industry itself and the state officials. Since the federal government has no police power in the states the federal men could never proceed except by consent, and they must always be the assistants of the state inspectors under such circumstances rather than an independent and all comprehensive force.

In a number of mining districts the operators, realizing the necessity of having a twenty-four hour local service, have combined to support local mine safety stations and crews. That at Globe, Ariz., is well known. The Coeur d'Alene operators this year established such a station and have found it very useful in fighting mine fires. The Bureau of Mines will always give all of the service that it can, but it must not be expected to give complete and continuous protection to each individual district. To do so would require an appropriation of funds far beyond any that might properly be suggested to Congress.

H. FOSTER BAIN,
Director, U. S. Bureau of Mines.

Know Any Queer Ones?

A correspondent writes: "Why not have a letter competition to see who can report the oddest named coal mine? For instance, 'Struggling Monkey,' mine near Terre Haute, Ind."

The lists are open.

Production and the Market

Weekly Review

Present indications are that the year 1923 will close with the fourth largest production of bituminous coal on record. With two weeks to go, the output to Dec. 15 was 526,489,000 tons and the year's figure will be over 540,000,000 net tons. Three years—1917, 1918 and 1920—have exceeded this figure. Anthracite production, on the other hand, promises to set a new high record for fresh-mined coal. The total output for the year will be around 95,000,000 net tons, exceeded only by the war years, 1917 and 1918. The washery production in those years was very large, however, and has been correspondingly small this year. Therefore the final figures may show a new record for fresh-mined anthracite. This has been the most prosperous year ever enjoyed by the hard-coal industry, despite the strike of September.

The end of the calendar year has no especial significance to the coal trade save that as the miners will take several days for the holiday there will be a cleaning up of "no bills" at the mines, to be followed by brisker trading after the new year begins. The only feature of the past week has been the pick-up in screenings, not due to any increase in demand but to scarcity of fine coal. The operators, rebelling at the absurdly low quotations on screenings in the Middle West, shifted to mine-run, the demand for lump being at low ebb. A period of severe weather will call forth lump in quantity and screenings will again be plentiful, and cheaper than ever.

Stocks Allay Uneasiness About April 1

There is no change in the steam-coal market in the Eastern section of the country. New England is flat as far as all-rail Pennsylvania soft coal is concerned; the smokeless coals coming in by water have driven them off the spot market. Stocks of soft coal are so generally satisfactory that no strong currents in the price are looked for, even should there be definite indications of a strike next April.

Coal Age index of spot prices of bituminous coal at the mines declined three points last week to 178. The corresponding average price was \$2.16. Increases in price were recorded by central Illinois, Indiana, and Smokeless. Southern and Eastern coals all recorded slight declines in price.

Production of beehive coke for the year will fall short of 17,000,000 net tons. Although more than twice the output in either 1921 or 1922, this figure is below previous years; less even than in 1919, when the steel industry was at low ebb.

Quotations on independent anthracite are slowly receding. The market stands at \$11 for stove and nut. The steam sizes are weak, except No. 3 buckwheat, which has largely been tied up on contracts. Nothing but a spell of real cold weather can save the premium prices from a new year slump.

Lake movement of soft coal during the week ended Dec. 16 amounted to 48,567 net tons, of which 46,204 tons was cargo coal. In the corresponding week of last year 53,086 tons was dumped. Cumulative shipments of cargo coal during this season to Dec. 16 were 29,724,320 net tons, an increase of more than 41 per cent over the average of the three preceding years.

Dumpings at Hampton Roads for all accounts during the week ended Dec. 20 were 355,927 net tons, as compared with 283,168 tons the previous week.

Midwest Markets Are Slow

Nothing has happened during the past week to stiffen up the weak and sagging markets in the Middle West. Domestic demand is just as soft as the weather. Lump, produced in small volume because of the proportion of shutdowns in the Western fields, is filling the light demand and there is no immediate indication of any improvement in price because of the potential production all ready to burst loose with the first cold wave.

The domestic market is pretty well saturated with Pocahontas lump and egg at \$3.50@3.75 and with mine-run at \$2, so that the flow of that and other high-grade Eastern

Estimates of Production

coals into the Middle West runs along lightly. Anthracite is in no keen demand by householders. The large sizes are stocked in volume by retailers and even chestnut is now on hand in sufficient quantity to meet all needs.

Steam coals show the only signs of life and these are selling readily only because of the slim output.

It is a rather "blue" Christmas in the Cartersville field of Williamson and Franklin County for most miners. Many mines have been idle for many weeks. Others are working one and two days a week and very few of them are getting more than half time at best. Railroad tonnage has eased up and the only thing for which there is any great demand seems to be screenings and small nut. All mines have domestic sizes unbilled. Movement is good and plenty of empties are in sight. There is a general feeling of dissatisfaction among the miners throughout the entire field.

The Franklin County operators are trying to maintain their circular, but this is being cut and the independents are selling lump and egg as low as \$3, with nut at \$2.75, in an effort to keep things going. Railroad tonnage in the DuQuoin field is practically stopped. In the Mt. Olive district steam seems to be in good demand, but it is diffi-

cult to move domestic sizes. This field continues to take \$3@3.25 for domestic sizes, which dealers seem to think too high. Mines in this field are getting from one to two days a week. Railroad tonnage is good. In the Standard field screenings are in good demand and 2-in. lump fairly active, with a ready call for steam nut, while egg and 6-in. lump are slow.

* Net tons, f.o.b. mines. † Advances over previous week shown in heavy type, declines in *italics*.

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

St. Louis Market Easy

Mild weather has brought about an easy market in St. Louis with very little domestic tonnage moving and that only of the cheaper grades. Country demand has practically ceased. Wagonload steam locally is fairly active and carload for nut and screenings good, with some nut moving to Chicago and the Northwest. Although trade is low all over Kentucky, even in the Eastern non-union fields where wages have been reduced in some instances to get business, there is hope springing eternal in the Kentucky breast. The fact of low production, however, strengthened screenings in both ends of the state. There is very little business other than steam just now, but almost everyone sees something ahead.

Northwest Awaits Winter

Mild weather is still holding the market at low ebb at Duluth, Minneapolis and Milwaukee. The selling competition between rails, lakes and lignite from Dakota continues to be keen and to hide any sign of interest on the part of buyers. Demand at Duluth for soft coal is off. In fact dock men report that this year is the dullest in several years. It is expected, however, that many of the mines on the iron range will be in the market immediately after Jan. 1, as water power is short, and they will need coal to operate. The only demand at present is from public utilities and power plants

which have been supplying water power. The market is generally firmer. Dock men feel that the buying streak must come and are sitting tight.

West Also Somnolent

Nothing disturbed the painful peace of Western coal markets during the week. Steam coal is generally in good demand with small supply but domestic supply more than meets all the needs. In Utah operators are getting from \$1 to \$2 less at the mines for all sizes of coal than they did a year ago.

Ohio Markets Demand Slack

Slack, screenings and small sizes hold the attention of the Cincinnati market. Low-volatile screenings are beginning to be demanded by the by-product trade. The extreme weakness of the market is shown in lump, particularly smokeless lump. Retail business was in a trifle better shape due to a snow flurry but soon fell back into the old rut. Outside of the small sizes, which are showing strength, the trade at Columbus is dull. Buying of steam and domestic sizes is limited, owing to heavy reserves in the bins and yards of dealers. The Cleveland market, like all others, was affected by the holiday season. The steam trade is quiet, inquiries are few and but little activity is expected before Jan. 1. The Pittsburgh coal market grew poorer last week both as to prices and as to the difficulty in making sales. Demand for spot coal is light, and but few consumers with contracts appear to be able to take extra tonnage. It is quite impossible to interest anyone in stocking coal against a possible suspension on April 1.

New England Buyers Show No Interest

On steam coal in New England there are few developments. Buyers show no interest in the current market, and now that there is less coal being forced on the market there is a pronounced lull throughout the trade. At Hampton Roads the amount of coal standing has been steadily cut down and as fast as the tonnage is moved there is less and less being sent from the mines to replace it. A few agencies are even buying spot coal to make good on commitments, and, as might be expected in a situation of this character prices are up slightly although the upgrade movement is extremely slow.

Tidewater Demand Slow

Weather conditions reduced consumption and affected the soft-coal market along the Atlantic seaboard. Demand was slow at all tidewater markets, due to both weather and the efforts of nearly all consumers to avoid adding to their supplies until after New Year's. At New York there has been some inquiry regarding contracts for next year, some of which expire early in January, but the matter of price is difficult to arrive at. The Philadelphia market continues dull and lifeless. There is no buying of any consequence and consumers do not appear to be anxious as to increasing their reserves. Baltimore reports that except for the demand for slack from the cement industry there is no sign of encouragement in that market. The Birmingham market continues slow and draggy. Steam coal is difficult to move and domestic grades move slowly. The trade, it is asserted is at about the dullest point of the year.

Anthracite Market Not Active

There is no great activity in the anthracite market. Demand for the various domestic coals is sectional, stove being in demand in some, while in others chestnut appears to be the most difficult to obtain. At New York cancellations of high-priced coals are being received by some shippers, while the general run of quotations for stove and chestnut appears to be around \$11. Egg coal was quoted as high as \$10.50. Retail dealers are not inclined to buy premium coal unless it is absolutely necessary. Philadelphia retail dealers are not rushed for deliveries, most of them having some supplies on hand to meet all requirements. Egg and pea is hard to move by producers and in some instances they find it necessary to insist upon buyers taking some of these sizes

with the preferred coals. There is no activity in the Baltimore anthracite market. The steam-coal market is dull and these coals are accumulating, although barley is in better shape than either buckwheat or rice.

Foreign Market And Export News

British Coal Output Gains

Production of British coal increased 10,000 tons during the week ended Dec. 8, output amounting to 5,729,000 tons, according to a cable to *Coal Age*. The output for the previous week was 5,719,000 tons, while for the corresponding week of last year it was 5,592,000 tons.

A sustained demand for almost all classes of coal maintains the activity of the Welsh coal market. There is a steady pressure for supplies for the balance of this year and over the first half of January. Most of the big mines are sold ahead, and new business probably will be done at higher prices. European business is increasing, especially with France, Belgium, Italy and Holland. The demand from Germany is slow. Business with other countries, including South America, is steady.

The only disturbing factor in the Welsh market is caused by the refusal of the trimmers to work the third shift at the ports. This refusal was a handicap, especially at Cardiff, it having come at a most inopportune time on account of the full order books of most of the mines.

The Newcastle market remains steady except that the return of stormy weather has delayed shipping. As a result there has been some prompt coal on the market and lower prices have been accepted. There is inquiry from Scandinavia and Germany, and France and Italy are also showing a disposition to do business. Operators are quoting current prices up to the end of March.

French Coal Market Dull

Demand for the French industrial coals is quiet, but movement of house coals is more active. Immediate needs are being covered, but with the cheapest grades. Anthracite and semi-bituminous are dull.

Imports of British coals are lower, buyers refusing to pay the high prices quoted as a consequence of the rise in sterling. Orders, close to 100,000 tons, have been placed in Cardiff by some of the French railways at prices of 26s. 6d. for large Admiralty second and 18s. 6d. for steam smalls, according to grades, for delivery during 1924.

Hampton Roads Market Weak

Business, generally, was duller at Hampton Roads last week because of the holiday season. The market was weak, but movement of coal held its own. Foreign movement showed a slight increase, while inquiries for export coals were somewhat brisk.

Coastwise trade was slow, but bunkers was good, and supplies of coal at tidewater increased. Ill effects of the Virginian Ry. strike, which threatened to tie up coal movement on that road, were being eliminated, and the Sewalls Point piers received almost normal coal supplies.

Domestic business showed little improvement, and prices at retail were weakening. Ten dollars a ton was the maximum for best grades of soft coal at retail, while prepared coal were selling one dollar higher.

Traffic News

Postponed Again

Another postponement of the effective date of the assigned car order has been made by the Interstate Commerce Commission until April 1, 1924. This is the sixth postponement, the commission's decision originally having been scheduled to go into effect Sept. 1, 1923.

Lehigh Would Control D. S. & S.

The Lehigh Valley R.R. Co. on Dec. 17 made application to the Interstate Commerce Commission for authority to acquire control of the Delaware, Susquehanna and Schuylkill R.R. by lease or ownership of its capital stock. The D. S. & S. has been used in the past for coal carrying only. It is a short line established by Coxe Brothers & Co. and is situated in the Hazleton district.

Install 9,179 Coal Cars

Of a total of 21,973 new freight cars installed in service during November, 9,179 were coal cars, according to the Car Service Division of the American Railway Association. From Jan. 1 to Dec. 1 177,845 new freight cars and 3,704 new locomotives have been installed by the railroads.

Balk at Higher Hard-Coal Rate

C. A. Bruce, secretary of the Twin City Coal Exchange, announced on Dec. 11 that the exchange will file a formal protest against the proposed increase in through rail rates on anthracite from the principal Pennsylvania mines to Minneapolis and other Northwestern points. The freight rate on anthracite, if changed, will mean an increased transportation cost of \$1.66 on a net ton of hard coal, Mr. Bruce said. Several other Northwestern organizations are planning to protest the proposed rail rate, according to Mr. Bruce.

Obituary

Benjamin F. Tarr, aged 78, a Civil War veteran, who is said to have erected the first coal tippie in Pennsylvania and also to have sunk the first double coal shaft in the state, died Nov. 30 in his home in Verona, Pa. He had been connected with various gas and coal operations until his retirement, eleven years ago.

Angus A. Ferguson, 56 years old, a well-known mining man in Nova Scotia, former manager of Florence colliery, later coal inspector for Scotia, and mining instructor died at Sydney Mines on Dec. 10.

Henry S. Hastings, of St. Marys, Pa., receiver of the Pittsburgh, Shawmut & Northern R.R. and the mortgaged properties of the Shawmut Mining Co. and the Kersey Mining Co., died at New Haven, Conn., Dec. 13, while visiting his son, who is a student at Yale University. At the time of his death Mr. Hastings was President of the Shawmut Mining Co., the Kersey Mining Co., the Shawmut Coal & Coke Co., the Shawmut Commercial Co., Clarion River Ry., Kersey R.R. Co., the Shawmut Holding Corporation of New York State, Shawmut Realty Corporation of Pennsylvania, and treasurer of the Byrnedale Coal Co. He was 58 years old.

Ralph E. Gilman, special engineer in charge of turbo-generator engineering of the Westinghouse Electric & Manufacturing Co., died in the Methodist Hospital, Los Angeles, Calif., Dec. 5. He was on leave of absence in an effort to improve his health. Mr. Gilman was a graduate of the Leland Stanford University, receiving his E. E. degree in 1898. He entered the employ of the Westinghouse company immediately after his graduation and beginning in January, 1901, he was located for two years in the engineering department. In 1903 he was transferred to the British Westinghouse Company and spent the next five years in London. In 1908 Mr. Gilman was recalled to East Pittsburgh and assigned to special duties in the power-engineering department. He was in this department continuously until the time of his death. He leaves a widow.

Association Activities

Opposition to government interference in private business was voiced at a largely attended meeting of directors of the **National Retail Coal Merchants' Association** in Washington Dec. 14 and 15. It was unanimously agreed to work for association aims, such as standards of coal, through co-operation with governmental agencies rather than by seeking more laws. The Washington headquarters of the association was charged with the duty of collecting all available data relative to the use of fuel oil and other substitutes for coal, for the benefit of dealers needing this information. In discussing "snowbirds," it was agreed that the proper course to pursue is to educate the consumer to recognize that it is better to deal with a permanent coal merchant who has an investment, is responsible and who will stand back of his sales in weight and quality. Secretary Mellon's tax reduction program was indorsed and a resolution to this effect was adopted to be sent members of Congress. President Coolidge's message to Congress was approved. There was informal discussion of the coal bills already introduced in Congress, and of other measures which it is understood will make their appearance. F. W. Schremes, of the Schremes Fuel Service, Kansas City, was elected a vice-president of the Association to succeed the late E. R. Sweeney, of the Sweeney-Bryan-Mitchell Co., Kansas City, who died recently. Bluefield, W. Va., was selected as the meeting place of the next annual convention, to be held in May.

Publications Received

Smoke Abatement, by Osborn Monnett, Bureau of Mines, Washington, D. C. Technical paper 273. Pp. 31; 6x9; illustrated. Discourses upon the pollution of the air, domestic smoke problem and gives results of tests of different coals. Plates showing starting of fires and the adding of coal are included.

La Destruction et La Reconstitution des Mines de Lens, Address before National Conservatory of Arts and Trades, March 12, 1922, by E. C. Cuvelette; 9 x 11 1/2 in., pp. 92, 47 full-page illustrations and 2 plates. Illustrations show mines before and after reconstruction. Publisher, L. Danel, Lille, France.

A pamphlet entitled "**Trade Standards Adopted by the Compressed Air Society**" has just been published embodying the result of extended study and research on the part of the executives and engineers associated with the members of that organization. It embraces the nomenclature and terminology relating to air compressors and their operations; a history of the development of speeds of air compressors; an explanation of capacities and pressures; instructions for the installation and care of air compressors with illustrations of devices suggested for cleaning the intake air; recommendation for the lubrication of air-compressing machines and the cleaning of air-receiver piping; a description of the low-pressure nozzle test recommended by the society, and a partial list of applications of compressed air. The Compressed Air Society has published this pamphlet with the belief that there is a need for such an authoritative work of reference, and that compressed air engineers and users as well as manufacturers of air compressors will appreciate this step toward the establishment of definite trade standards in the industry. Copies may be had from the members, or by addressing the Secretary of the Society, C. H. Rohrbach, 50 Church St., New York.

Coal Legislation Hopper

Representative Newton, of Minnesota, introduced in the House, Dec. 20, a bill authorizing government agencies to gather information about the coal industry. The bill gives the Federal Trade Commission authority to obtain information and make reports about ownership, production, distribution, stocks, investments, costs, sales, margins and profits in the coal industry. The Interstate Commerce Commission is authorized to obtain reports from the railroads relative to car distribution, mine ratings and similar questions. The Geological Survey is authorized to obtain information and make reports relative to coal production. The Secretary of Labor is authorized to obtain information relative to wages and labor conditions. The President is authorized to declare an emergency when in the judgment of the Federal Trade Commission such action is warranted. During such emergency the President would have power to deal in coal and to control production, movement and distribution of coal.

Trade Literature

Flanged Obround Condulets, Four-page folder published by the Crouse-Hinds Co., of Syracuse, N. Y., describing covers and wiring devices for Flanged Obround Condulets.

Reliance Electric & Engineering Co., Cleveland, Ohio, has issued a neat little book entitled "Electric Motors—How to Choose and Use Them." It has 32 pp., is 3 x 6 in.; illustrated.

News Items From Field and Trade

ILLINOIS

The United Electric Coal Mining Co. during the past year has purchased 2,500 acres of strip coal lands within three miles of Cuba, Ill., at a cost of \$300,000. The company is now building a steel tippie and grading plant of 4,000 tons capacity in eight hours. Three steam shovels, each costing \$110,000, and railroad tracks and switches costing \$250,000 have been erected. The total investment is expected to exceed \$1,000,000.

After two years and a half of development work, initial production has been reached by the new Shuler Coal Mining Co. mine at Alpha. The mine is now producing 100 tons daily, but in a few weeks the output will be raised to 300 tons. By next year the company expects to be producing 1,000 tons daily. As the Shuler company will attempt to market the bulk of its product in Davenport and Bettendorf, Iowa, and Moline, East Moline and Rock Island, Ill., it is believed that the competition will be keen in the steam coal line when this big mine has once been put on a capacity production basis. The company has 2,000 acres in the tract where development is now taking place. Charles Shuler, of Davenport, president of the Iowa National Bank and owner of extensive coal lands in Colorado and Iowa, is the head of the concern, and Charles Shuler, Jr., is the manager at the new mine in Alpha.

The Tiger Coal Co., Cuba, Ill., has opened a shovel mine, at a cost of \$100,000.

INDIANA

On application of the Consumers Coal Co., of Indianapolis, John F. Heinze, a coal operator of Boonville, has been appointed receiver of the Key Coal Co., which has operated a mine near Boonville. The coal mine has not been in operation since March 15.

"There appear to be too many mines and miners," said William Mitch, secretary of District 11, United Mine Workers, recently in commenting on reasons why Indiana mines are shut down 40 per cent and why the other 60 per cent is working only half time. John Hessler, district president, said freight-rate adjustments to give Indiana coal a better competing chance would help.

The Primrose Coal Producing Co. of Indianapolis, has been dissolved. William Schroluche was president.

KENTUCKY

Early in the coming year the Northwest Kentucky Coal Association will move its offices to the recently completed Ashland National Bank Building. A number of operating companies in the Big Sandy field will establish offices in the new bank building. John E. Buckingham, a pioneer in the development of the Big Sandy field, is president of the Ashland National.

MASSACHUSETTS

Eugene C. Hultman, State Fuel Administrator, estimates that the total cost to the people of Massachusetts for heating their homes with anthracite during the current year will be \$90,000,000, double the cost of eight years ago. He says that this coal bill consists of \$50,000,000 for the anthracite at the mines in Pennsylvania, \$20,000,000 for transportation to Massachusetts, and another \$20,000,000 for delivery and other charges to the consumers' cellars.

MISSOURI

At a meeting Dec. 15 the board of directors of the Central Coal & Coke Co. declared the regular dividend of 5 per cent on preferred and 6 per cent on common stock. John H. Kirby, who recently acquired a controlling interest in the company, was elected to the board to succeed C. F. Fox, and Thomas Mackie, general purchasing agent and a stockholder, was chosen to succeed J. R. McAllister.

NEW JERSEY

Joseph Malloy, formerly of the Clearfield office of Halden-Kelley Coal Co., has been transferred to the Newark office of the company. He will be in charge of the office management under Ira M. Van Vliet.

NEBRASKA

The East mine of the Brewerton Coal Co., which has been closed for two months, as the result of labor trouble, resumed operation on Nov. 27 and the work of cleaning up the mine preparatory to hoisting coal was started. The closing was the climax of a series of short shutdowns due to labor trouble.

NEW YORK

The Westmoreland Coal Co. on Dec. 18 declared an extra dividend of 1 per cent and the regular quarterly dividend of 2 per cent, payable Jan. 2 to stock of record Dec. 27.

A. T. Ward of the Acme Coal Mining Sales Corporation has transferred his office to 1 Broadway, New York.

Colonel Oscar H. Fogg has resigned as secretary-manager of the American Gas Association. Colonel Fogg, who has headed the gas association since 1919, leaves to assume the position of president and general manager of the Baltimore Gas Appliance & Manufacturing Co., Baltimore, Md. Alexander Forward, of Richmond, a member of the State Corporation Commission of Virginia, has resigned that post to accept the position with the American Gas Association made vacant by the resignation of Colonel Fogg. The American Gas Association has a membership of more than 500 manufactured gas utilities in the United States and Canada.

OHIO

The Stark Mineral Co. has been chartered with a capital of \$10,000 to operate coal mines in the Tuscarawas field as well as to produce clay and other minerals. Incorporators are: Thomas C. Eayrs, Frank F. Bamberger, M. H. McCormick, W. L. DeHoff and Joseph A. Miller.

The Co-Operative Coal Co., Cleveland, has been chartered with a capital of \$10,000 to operate coal mines and sell coal at wholesale and retail. Incorporators are John K. Frye, Ray J. Curry, Della I. Curry, Georgeanne A. Frye and H. H. Henry.

The Ohio-Cities Coal-Supply Co., Akron, has been incorporated with a capital of \$500,000 to buy, sell and mine coal. Incorporators are S. R. Enderton, M. D. Hubbard, W. D. Stuhldreher, L. W. Rinear and H. E. Kepler.

A charter has been granted in Delaware to the Antiquity Coal Corporation, with a capital of \$800,000. The incorporators' names are: Elmer H. Holmes, Syracuse, Ohio; Charles Ebersbich, Pomeroy, and L. D. Davis, Middleport, Ohio.

OKLAHOMA

The Wise Mine of the Henryetta Coal & Mining Co., at Okmulgee, was badly damaged by a cave-in on Dec. 9. The loss is estimated at \$100,000. The Wise is one of the oldest coal shafts in the Henryetta field.

PENNSYLVANIA

A. B. Sheets, of Pittsburgh, Pa., vice-president of the Hillman Coal & Coke Co., has been elected to the board of directors of the Oakland Savings & Trust Co., Pittsburgh.

The four and a half mile belt conveyor system and two 35-car rotary dumps to feed the belt, being installed by the H. C.

Frick Coke Co. to convey the coal underground from their three Colonial mines at Grindstone and Smock, Fayette County, to the River near Fayette City is expected to be ready for operation by Jan. 1.

W. A. Chandler, consulting engineer for the Hudson Coal Co., has appointed C. J. Adams as electrical engineer to succeed James James, resigned, who has accepted a position with the Lehigh Coal & Navigation Co. Mr. Adams was formerly assistant consulting engineer for the Hudson company. R. J. McClure has resigned from the engineering department of the Hudson company, and J. F. Lewett has been named in his place.

The Philadelphia & Reading Coal & Iron Co., through J. F. Whalen, chief counsel, at Pottsville, on Dec. 18, resolutely opposed any settlement of the suit for taxes brought by the Schuylkill County Commissioners at a hearing before Judges Bechtel, Koch and Berger. Mr. Whalen, said that it was the purpose of the corporation to get a definite judicial decision on the heavy increase in taxes on its lands irrespective of any settlement made by other companies with the County Commissioners, and a decision solely upon the evidence presented.

The general grievance committee representing the 17,000 miners of the Lehigh Valley Coal Co. between Wilkes-Barre and Old Forge, at a meeting in Exeter, Dec. 14, decided to call off the strike, and have their grievances adjusted under the direction of District President Cappellini. The district president told the men that Mr. Thomas had agreed to reinstate the five miners discharged at the Maltby colliery for refusing to place a 9-in. topping on their cars, and that Mr. Inglis had assured him that no time would be lost by the conciliation board in taking up the grievances of the Valley miners.

Branson, Long & McFadden, Inc., with offices in Philadelphia, Johnstown and Pittsburgh, have sold their business to the Triangle Coal & Coke Co., of Pittsburgh, as of Jan. 1, 1924. The latter company was recently incorporated in Pennsylvania with a capital stock of \$25,000 by W. B. Atwood, president of the Bunker Coal Co., and his associates. Branson, Long & McFadden, Inc., have acted as sales agents for Bunker coal together with other high-grade steam and gas coals and the business will be carried forward by the new company in the same manner as before. J. L. Sease, E. C. Dodson and N. L. Parkins, formerly of Branson, Long & McFadden, Inc., will be in charge of the Philadelphia, Johnstown and Pittsburgh offices, respectively. The main office of the company will be consolidated with the offices of Bunker Coal Co. in the First National Bank Building, Pittsburgh, Pa.

Fire destroyed the Tip Top breaker of the Beaver Valley Coal Co., west of Hazleton on Dec. 10. The breaker has not been in operation this month, owing to a strike called on Nov. 30 by 150 of the workmen. The strike was due to the discharge of a foreman and the claim that a spy system had been in vogue. The company lacked fire-fighting facilities there and once the fire was started it could not be checked.

The first semi-annual meeting of the Coal Mining Institute of the Ninth Bituminous District was held on Dec. 1 at Connelville. S. S. Hall, mine inspector of the Ninth District, presided and addresses were made by John L. Gans of *The Weekly Courier*; Captain Steidle, of the Mining Department of Carnegie Institute of Technology, Pittsburgh; J. E. Struble, of H. C. Frick Coke Co., and Richard Maize, of Uniontown, president of the Coal Mining Institute of America, and others.

The Clearfield Bituminous Coal Corporation has been granted a permit for the enlargement of the existing impounding reservoir on Hinty's Run, the source of the water supply for the company's village of Commodore, Green township, Indiana County.

A state permit has been issued to the Jefferson & Clearfield Coal & Iron Co. for the construction of a waetr-works system in its mining village of Aultman, Centre township, Indiana County.

The Central Pennsylvania Coal Producers' Association has resumed publication of its "Bulletin" which was suspended some time ago. The co-operation of all members of the association is sought in order to make the publication a success.

L. N. Williams, it has been announced has become traveling coal freight agent for the Baltimore & Ohio, with headquarters at Pittsburgh.

The Lehigh Valley R.R. has started to store soft coal for use on engines on the Hazleton & Mahanoy division of the road, it was announced on Dec. 17. There is a pile of the fuel totaling between 10,000 and 12,000 tons at Delano, which was gathered last spring and summer, and to this has been added between 2,000 and 3,000 tons during the last few weeks.

Miners employed by the Pennsylvania and Hillside Coal companies in northeastern Pennsylvania had a record output of coal on Dec. 15, according to company officials, who say that 33,870 tons was prepared and shipped to the market in eight hours. The upper district of the Pennsylvania Coal Co. led with 21,870 tons to its credit. The lower, or Pittston district, turned out 12,000 tons, which was a light increase in production for this district, which prior to 1920 turned out as high as 15,000 tons of coal in a day. In the record made the No. 1 colliery, at Dunmore, had the largest output, 7,500 tons. For the past few months the mines of the Pennsylvania and Hillside companies, in the Pittston district, have not been hampered in production by petty strikes.

S. J. Phillips, state mine inspector, at Scranton, in a letter mailed to the Carnegie Hero Fund Commission called the commission's attention to the heroism displayed by Eben Jones, mine foreman at the Mount Jessup mine, who on Dec. 8 in an attempt to warn four fellow-workers of impending danger, was himself imprisoned with them under a fall of hundreds of tons of rock and coal. His body has since been recovered. Mr. Phillips describes the act of the hero-foreman as "one of the most heroic ever recorded in the anthracite field," and urges that the commission do its utmost in rewarding the hero.

Joseph J. Walsh, Secretary of Mines, told the Governors' Conference, at Harrisburg, on Dec. 14, in opposing the repeal of the certification law, that there are enough miners in Pennsylvania now. He added, however, that there was room for 22,000 additional laborers, on whom there are no restrictions in the way of required qualifications.

Although Mrs. Eckley B. Cox, wife of the late Senator Cox, pioneer anthracite operator, is seriously ill at her home in Hazleton, the forty-eighth annual visit of the "Coxe Santa Claus" was made to 3,000 school children of Beaver Meadow, Buck Mountain, Eckley, Stockton No. 7, Oneida, Tombick, Derringer, and Garven. Each boy and girl received a new \$1 bill and a half pound box of chocolate candy.

UTAH

Entry on 900 acres of coal lands in the Fish Lake National Forest is being protested by the field department of the U. S. Land Office. It is claimed that Olive Beebe, Rank Foote, Oscar Beebe, John F. Beebe and May B. Browning, claimants of the land, had not improved a mile of coal up to July 26, 1906, the date the government took over the preserves. The land in dispute is about eight miles from Emery.

The Utah Fuel Co. has announced its intention to test the constitutionality of that section of the Utah Workmen's Compensation law which provides that in addition to the burial expenses the employer of a person who dies leaving no dependents shall pay to the State Treasurer 20 per cent of the amount that would have been due such dependents. The question is now being considered by the Industrial Commission and is expected to go before the Supreme Court at an early date. If the law is not upheld a second problem will be the disposal of the \$30,000 which has been collected under the law so far.

WEST VIRGINIA

George R. C. Wiles, former chairman of the West Virginia Public Service Commission, speaking at the Lions Club Luncheon, Dec. 14, at Charleston, said that the trouble with the coal business in West Virginia is over development and the remedy for the situation is less government regulation through commissions and investigations and the establishment of fair competitive conditions. "Investigations and the creation of commissions can only result in the producers losing and the consumers paying," he concluded. "Give us fair competitive conditions and the law of the survival of the fittest will make West Virginia the greatest coal-producing section in the world."

Less than 1 per cent of the coal in West Virginia has been mined and at the present

rate of production the supply in West Virginia will last for 1400 years, Stephen Hays, general engineer of the Westinghouse Electric & Mfg. Co., said in an address before the Business Club of the West Virginia University. He also asserted that the available coal area in West Virginia is about 9,500 square miles, sheltering something like 60,000,000,000 tons of good coal and about 100,000,000,000 tons of low-grade coal.

A jury in the U. S. District Court at Charleston on Dec. 12 returned a verdict recommending judgment of \$899,054.60 for the White Oak Coal Co. from the United States Government. The company sued to recover that amount by representing the difference between the price paid by the Navy Department for coal requisitioned between July 1, 1919, and April 1, 1921, and the prevailing market price. Approximately 210,000 tons of coal was requisitioned at that time, the coal company asserted. Motion was made for a new trial by U. S. Attorney Elliott Northcott, who requested 60 days in which to prepare and file his reasons for a new trial.

The Valley Fuel Co. has increased its capital stock from \$100,000 to \$500,000 and the Kenawha Valley Coal Co., of Charleston, has increased its capital stock from \$100,000 to \$2,000,000. The Jake Henry Coal Co. has changed its general plan of stock issue from 3,000 shares of common stock to 2,500 shares of common stock and 500 shares of preferred stock, and the Indian Run Collieries Co. has changed its general plan of capitalization from 3,000 shares of preferred and 7,000 shares of common stock to 10,000 shares of common stock. The Behler Coal Co. and the Flat Run Gas Coal Co. have filed notices of dissolution with the Secretary of State of West Virginia.

There has been more activity among some of the larger mines in the New River field since Dec. 1. All sixteen of the mines of the New River Company, which had been working on a part-time basis, started working full time soon after the first of the month.

WISCONSIN

The late Edward A. Uhrig, president of the Milwaukee-Western Fuel Co., left an estate valued at \$4,361,489.42, according to the inventory and appraisal filed with the Probate Court, Milwaukee, Dec. 12, 1923. The inventory includes 10,700 shares of stock in the fuel company, held to be worth \$3,152,220. The deceased gave 911 shares of stock in the company, valued at \$268,380, to his son, Alex. B. Uhrig, some years prior to his death. His salary as president of the Milwaukee-Western Fuel Co. was \$18,000 per year. The entire interest of the Uhrig family was acquired by Pittsburg interests some months ago. Joseph W. Simpson is now president of the company.

The Milwaukee Western Steamship Co., subsidiary of the Milwaukee Western Fuel Co., has sold the two coal steamers, the Joseph W. Simpson and the Alex. B. Uhrig, to the Reiss Steamship Co., of Manitowoc, which is controlled by the Reiss Coal Co. The Reiss company now has eleven vessels in the lake coal traffic.

WASHINGTON, D. C.

The annual budget for the fiscal year ending June 30, 1925, submitted to Congress by President Coolidge, shows that the U. S. Coal Commission expended \$452,195.56 of its \$600,000 appropriation, that the expenditure for 1924 will be about \$138,000, leaving approximately \$10,000 to be returned to the Treasury. Among the other items of interest to the coal industry contained in the budget are: \$14,500,000 for coal and other fuel, including transportation, for the navy; \$4,250,000 for fuel for the army; \$1,805,272 for the Geological Survey; \$1,909,573 for the Bureau of Mines; \$78,000 for continuation of the investigation of mineral resources of Alaska, and \$136,734 for the preparation of reports of the mineral reserves of the United States, including special statistical inquiries as to production, distribution, and consumption of the essential minerals.

Dr. R. R. Sayers, chief surgeon of the Bureau of Mines, is in England on the last lap of a trip which has included a study of health conditions in mining communities in Australia, New Zealand, South Africa, and Europe. Dr. Sayers expects to arrive in Washington the latter part of December or the first of January.

Agreement between a labor union and employers which results in a limitation upon production is not a violation of the Sherman anti-trust law, at least in a specific case where the public interest was not affected, according to the decision of the U. S. Supreme Court, Dec. 10, reversing a decision of the lower courts in granting the government an injunction against the National Association of Window Glass Manufacturers, the National Window Glass Workers and others. The union and the association last year negotiated a contract in two parts, one to run from Sept. 25, 1922, to Jan. 27, 1923, and the other from Jan. 29 to June 11, 1923. It was provided that no employer could have both contracts. This resulted in closing those plants which did not have a contract. The object was to provide practically continuous employment for the 2,500 members of the union, which makes hand-blown glass, as business was insufficient to operate all plants continuously because of the competition of machine-made glass. One end to be accomplished was to prevent skilled workers from leaving the industry because of part-time employment. Although the lower courts declared this to be a violation of the Sherman act, the Supreme Court, through Justice Holmes, held that there was no conflict between this contract and the law.

Charles L. Dering, president of the American Wholesale Coal Association, has appointed the following committee to serve on Advisory Committee to the Coal Division of the Department of Commerce: Charles L. Dering, Chicago, Ill.; Borden Covell, vice-president (president Northern Coal Co.), Boston, Mass.; Seth W. Morton, Member of Senior Council (sales manager of W. G. Morton), Albany, N. Y. Alternate members: Benjamin H. Read, Director (Lynah & Read), Baltimore, Md., and G. H. Snowdon, director (president of the G. H. Snowdon Co.), Pittsburgh, Pa.

Washington retail coal dealers, represented by J. Maury Dove, Jr., president of the Coal Merchants' Board of Trade, and by officials of the National Retail Coal Association, presented to Secretary of the Interior Work on Dec. 14 a proposal to take over the entire government coal business in Washington. Secretary Work took the proposal under advisement, and prior to familiarizing himself with the details of the proposition, asked the dealers to withhold the provisions of their proposal.

CANADA

Lack of employment at some of the mines of the British Empire Steel Corporation at Sydney has become so serious that the provisional officers of the United Mine Workers at Glace Bay have appealed to Prime Minister W. L. MacKenzie King and other Canadian officials for relief. After stating that the mines are working only one or two days a week and some weeks not at all, and that some of the families are in destitute circumstances, the union leaders in their telegrams to the authorities say that it is their opinion that the government of Canada should make arrangements to take coal from these mines, so as to relieve the unemployment situation, instead of buying coal from the non-union coal operators in the United States.

Alberta Ontario Coal Imports, Ltd., of Toronto, has been incorporated with a capitalization of \$50,000. The provisional directors are Norman S. Robertson, George McC. Willoughby and Harold L. Steele.

The Western Coal Co., Ltd., has been organized at Toronto and has been granted an Ontario charter to carry on business as a coal operator. The authorized capital is \$40,000 and the provisional directors are H. A. Newman, M. R. Newman and F. M. Waizman, all of Toronto.

The last shipments of coal for the season have been made from the Nova Scotia coal mines to the St. Lawrence ports. The total shipments for the year to the St. Lawrence market are approximately 1,100,000 tons, which is an increase of 84,000 tons over last year, but less than was expected early in the decision. Many buyers during the strike transferred their orders from Nova Scotia to the United States.

As a result of the 1922 coal strike official government figures on exports of coal to the United States from Nova Scotia—the great bulk of which comes from the collieries of the British Empire Steel Corporation—show a striking gain for the coal year, ended March 31, 1923. Figures for the last three years, ended March 31, are as follows: 1921, 42,479 tons, valued at \$417,233; 1922, 16,057 tons, valued at \$129,322; 1923, 58,073 tons, valued at \$3,557,101.

New Equipment

Disk Mine Fan Fitted with Aeroplane Blades

Ship and aeroplane propellers always have had curved faces. It is natural that the blades of mine fans should be similarly constructed. A new mine ventilator with curved blades known as the Robinson Coniflo Disk fan is now being manufactured by the Robinson Ventilating Co., of 6027 Jenkins Ave., Pittsburgh, Pa. In eight comparative tests conducted by some of the largest coal companies these fans of equal size to those they have replaced are said to have produced larger volumes and higher pressures, operating at the same speeds and using the same motor.

Every fan operating at high speed and against high pressure has a marked short-circuit in the center of the wheel. This is called the back flow. It is caused by the peripheral speed reaching a maximum at the tips of the wheel and being practically zero at the roots of the blades. It is claimed by the manufacturer that this fault cannot be corrected by overlapping the blades be-

capacity and a greater mechanical efficiency than would otherwise be attained. The curved blades and the large center disk also give the air a much higher speed per revolution and permit the fan to be fairly efficient against pressure up to 2½ in. gage.

Compactness saves erection difficulties and makes the fan more portable. The fact that the blades are stamped from heavy sheets, riveted and braced by heavy plates to the center disk makes the wheel so strong that it can be operated to 1,000 r.p.m. Rods, bolts and nuts are eliminated in the bracing, consequently the braces cannot work loose. The balance also is maintained at all speeds. Either ring oiling or ball bearings can be used.

Centrifugal Pump to Handle Water with Dirt Solids

The Wilfley centrifugal sand pump, recently developed by the A. R. Wilfley & Sons Co., Denver, Colo., has as an important feature the elimination of the stuffing box, which in most centrifugal pumps gives considerable trouble when pumping gritty material.

The seal on this pump consists of a revolving member having radiating wings, called an "expeller," which prevents the material from leaking out by centrifugal action. An automatic check-valve seal is around the shaft while the pump is not in operation. Another important feature of this pump is the slippage seal adjustment. When this slippage occurs, as it does to some extent in all centrifugal pumps, it causes a reduction of capacity and efficiency. This leakage depends upon the clearance between the runner and the side plate. Gritty water in time increases this clearance and therefore cuts down the efficiency.

It will be interesting to note that this pump is fitted with ball bearings. The bearing assembly is of unit con-

PUMP FOR COAL WASHING

The wet process of coal washing and separation requires pumping of water containing much grit. A pump capable of meeting this condition must be simple, efficient and able to resist wear.

struction, independent of the frame.

The wearing parts are all easily replaced in a few minutes, and this quick change feature is particularly valuable where a spare pump is not available or when the nature of the material handled is gritty, such as is the case where coal washing and a wet preparation process is used.

Mine-Car Retarder

In many cases the grade approaching the cage or dump is so steep that it is impossible to put in a cager or stops of any kind, as the load of the trip will bend the axles of the cars. Then again it is often desirable to control a trip of cars on steep grades. A device known as the Nolan mine-car retarder rubs the surface of the wheels of two or more cars and brings such pressure upon them that the cars can be brought to a complete standstill, if desired, and released so that the cars will move forward one, two or more at a time.

On one side of the track is a fixed guide which consists of a heavy channel, securely bolted to the ties. On the other side is a similar channel which is movable, and is moved in and out against the wheels of the cars by means of a hand lever situated wherever desired. This second channel moves upon slide plates and a spring will move it into its inoperative position, whenever the pressure from the lever is released. It is asserted that one man, by means of this simple machine, can control a long and heavy trip and feed the cars as desired.

The complete equipment is now being placed on the market by the Mining Safety Device Co., of Bowerston, Ohio.

FAN BUILT TO PREVENT BACK FLOW

The fan revolves in the direction of the hands of a clock. Air leaves the blades not only near the casing but also near the disk. In consequence the pressure is more nearly equal over the whole airway ventilated.

cause this restricts the space through which the air must travel and slows the speed of the air through the wheel.

To a large extent the back flow is avoided with this fan because it is provided with such liberal space that the air can travel through the wheel at speeds that will create the pressure desired. The curvature of the blades assists the air to take a direction parallel to the axis of rotation of the fan and the large disk in the center of the wheel retards the back flow. The air is not discharged violently against the casing but along the edges of the blades. This gives the fan a higher volumetric

MINE-CAR RETARDER

The movable sidepiece puts pressure on the side of the car wheels and in this manner stops or retards the cars.

GENERAL ELECTRIC

Hidden Values

TO attempt to learn the quality of the products manufactured within the walls of a busy industrial plant by merely looking at the outside would be impossible and ridiculous. No more so, however, than to attempt to judge the dependability of a locomotive crane by merely looking at it.

Far down in the heart of every crane bearing the Brownhoist name lies the secret of its quality and dependability. Built into every part of every Brownhoist is something that even the shrewdest buyer cannot detect by casual observation. This is the careful choice of materials and the precision of design and manufacture.

The Brownhoist name-plate on a

locomotive crane is not only a guarantee of fine materials but it also means that to these materials has been added a manufacturing skill of the highest order. Nowhere, on work of this type, will you find more accurate machine work or more exacting care in assembly.

To make locomotive cranes of better quality, greater dependability and a longer useful life are the ideals toward which Brownhoist is constantly working. The measure of success attained is best evidenced by the records for dependability and economy of operation that have been made by Brownhoist cranes on all kinds of work.

If you are interested in the economical handling of materials, just write us.

The Brown Hoisting Machinery Co., Cleveland, Ohio

Branch Offices: New York, Chicago, Pittsburgh, San Francisco, New Orleans

Brownhoist Products

Brownhoist builds locomotive cranes, buckets, monorail trolleys, chain conveyors, belt conveyors, bridge cranes, heavy dock machinery, and other material handling equipment.

Greetings

*This is the in-between issue of
Coal Age. Christmas is past;
the new year is just ahead.*

*Coal Age extends to all that
old but ever new and always
welcome greeting*

Happy New Year

Tomlinson Automatic Car Coupler and Spring Bumper for Mine Cars

The advantages and necessity of automatic couplers and spring bumpers for mine and industrial cars have long been apparent to those who have operated the heavier types of cars where they are operated in trains and hauled by locomotives.

To fulfill these requirements O-B is now offering to the mining and industrial field a modification of the well known Tomlinson Automatic Car Coupler. This type of coupler is standard on most of the electric railway properties in the United States, Canada and many of the foreign countries, where automatic couplers are used. Its merits have been proven, as it is in use on probably 50,000 cars scattered over the world—on several hundred different railways.

The operation is strictly automatic—requires no preliminary adjustments or alignment.

It couples by impact either on straight track, curves or vertical breaks in grade. Uncoupling is accomplished from either side of the trip with no danger to the operator—fully complying with all the safety appliance requirements now in force on steam railroads of this country.

The face of the Tomlinson coupler is a large flat surface and it has adequate spring draft gear to compensate for the bumping shocks—thus saving the car frame and body.

The Tomlinson Mine Car Coupler is designed so that it can be used on cars of the end dumping or rotary type. The rotary type may be dumped without uncoupling.

In fact, the Tomlinson Automatic Mine Car Coupler meets every requirement for operation of mine cars in trains.

Demonstration on your property can be arranged through consultation with any of our representatives.

FAN

Where Jeffrey Equipment
is made—

NOTE how the complete steel casing extending to the ground, eliminated masonry and simplified the installation of this Jeffrey Fan at the Pursglove, West Virginia, mine of the Cleveland & Morgantown Coal Company.

A 7 ft. x 3 ft. 6 in. Double Inlet Blowing Fan, it has a maximum capacity of 150,000 cu.ft. per minute, with a normal capacity of 125,000 cu.ft. per minute arranged for belt drive from motor.

The Jeffrey type of casing here shown is of drift-mine application. A Jeffrey Blowing Casing may be built with steel hood extending over on air shaft or arranged for blowing into a drift or slope mine. Other Jeffrey casings include the Exhausting, Primarily Blowing Reversible, and Primarily Exhaust Reversible. The service of Jeffrey engineers is at all times available in helping determine the most practicable type of fan and casing.

HOISTS

Three Wise Men and the East

The brains of the Ample Steam Coal Co., comprising the superintendent, "Jack" Bream; the foreman, "Doug" Walls; and electrician "Peep" Cassidy, rubbed shoulders in a dog-hole off one of the East Haulage-way entries, while a trip of loads on the down grade thundered by to the tune of an incessant and discordant clanging of the locomotive gong.

With the passing of the tippie bound cars, the three huddled figures disjointed themselves from what appeared to be a compact unit of humanity, and with arched backs took up their journey to the outside.

The conversation began at the point where it had been interrupted in the scramble for safety. "Well, you fellows", Walls opened up, "got a good sample this morning of what we have to put up with down here in this section in the way of rotten voltage. I might call conditions on that East feeder line 'shocking', if it wouldn't be for stretching the truth. Guess you'll believe me after this when I report a mining machine stopped dead in its tracks with a smouldering armature, or another trailing cable going up on high in a blaze of glory."

Not to be denied, he continued: "We've got too much load on that section feeder and none on the

South. We could scamper a lot more coal out of that section if we had better power down there. Why can't we tie those two feeders together, I wants to know? Wouldn't that set us right, 'Peep'."

The Circuit Breaker with Brains

"Yes and No", 'Peep' replied. "No question but what it would largely solve our voltage troubles, but you'll never win me over to tying those section feeds together solid. With all of that bad roof in the South, you would be knocked out

of more time on 'shorts' than what you would gain in better voltage."

"Nope, what we ought to do—", 'Peep' glanced out of the corner of his eye toward Bream, "is—"

"Out with it" grunted the 'Super'. "Your monthly envelope is supposed to take care of an occasional stray new thought. If you feel one coming on get it out of your system."

"Tie those feeders together with an automatic reclosing sectionalizing breaker", 'Peep' responded with zest. "That would let the East section enjoy all of the advantages of being tied in with the South without any of the disadvantages. A 'fall' then wouldn't tie up operations in both sections tighter than a wet knotted sock."

"But, of course, that means spending a few dollars", 'Peep' added, "and, as you know 'Doug', our Boss is strictly 'agin' that sort of thing."

"Looks to me like a plain case of conspiracy with intent to mutiny", Bream laughed. "You're a wiser bird than I give you credit for being, 'Peep'."

"Don't hand me any bouquets", 'Peep' chuckled. "Slip your flowers to 'Doug'."

"You know 'Peep'", Walls came right back, "the Chief is no dumb-bell himself."

NO REPAIRS

PERFECTLY satisfactory and no repairs." This is the statement from the engineer in charge of the Terry Turbines, installed at the Lever Bros. Co., Cambridge, Mass. This is not typical of all Terry turbine installations, for it must be recalled that Terry turbines were being manufactured over twenty years ago. There is no moving mechanism built, which will run forever with out replacing the wearing parts, and the Terry turbine is no exception to this rule. For this very reason The Terry Steam Turbine Company maintains a very complete and extensive stock of repair parts ready for immediate shipment and a force of trained men in the field for the purpose of making replacements when necessary. The fact that Lever Bros. have as yet made no repairs is significant of the fact that Terry turbines with the proper attention to lubrication and adjustment are free from operating kinks and troubles and will continue to give good service during the calculated life of their wearing parts.

Write for Bulletin No. 25-A, which contains a complete detail of these working parts and loads and stresses imposed upon them. You will then appreciate how small your replacement charges will be, should you select

Goodness Man, Throw Away Those Old-Fashioned Cars and Get Up-to-Date With Automatics!

How Can You Expect to Compete When You Are Spending All That Extra Money on Labor, Repairs, Haulage, Etc.?

USE—THE CAR FOR HARD TIMES

- (1) No tippie labor in dumping coal or slate, all automatic.
- (2) Big output for a small investment—few cars and motors, and no dumping machinery.
- (3) Big tonnage on a flexible little car.
- (4) No repair costs to speak of.
- (5) Operating troubles disappear. Too many savings to itemize here.

Get Catalog Section No. 6 (32 pages of information).

The mine equipped with "S. & D. Griffith" Automatic Drop Bottom Cars

Prosper in Hard Times As the Woodward Coal Company wrote us:

Kent, Ohio, Nov. 26th 1923.

"We have just received your letter and the new Catalogue of the automatic cars. You certainly have placed this car into the Catalogue in a very plain and comprehensive manner. I enjoyed the "layouts" in the last five pages very much and think this is a good idea to carry them there and believe they could be even further elaborated.

"So far as the car itself is concerned we have used them now about a year and *could not be induced to go back to the old style end dump cars under any consideration.*"

Old Mines are discarding old-fashioned cars and for new mines the "S. & D. Griffith" Automatics are rapidly becoming standard equipment.

Sanford-Day Iron Works Knoxville, Tenn.

**Some of the 2000 questions
answered for you in
Mine Examination Questions
and Answers**

- can a miner live in air in which the oxygen content is reduced to 17 per cent?
- what are the conditions under which the presence of the various mine gases may be expected?
- what is the highest explosive point of firedamp?
- is there any danger in the installation and use of a gasoline motor in a mine?
- what qualifications are necessary to make a successful mine foreman other than those required by law?
- what are the legal duties of a fireboss?
- how would you ascertain the number of cubic feet of gas standing in an entry?
- what quantity of air will be required to ventilate a mine working 250 men, 12 mules and using 3 gasoline haulage motors?
- what would you do if put in charge of a mine that was not properly ventilated?
- what is the difference between a 10 per cent pitch and a pitch of 10 degrees in a seam?
- how would you test a steam boiler to ascertain its safety?
- what style of rope is best adapted to hoisting in ordinary coal mining practice?
- what is meant by permissible explosives?
- Etc., etc.

—“of vital interest to those around the mines who desire to obtain certificates of competency”

—says Coal Age

PRACTICALLY every question that has ever been asked by a mine examining board in recent years is in these three books. The answers and illustrations are wholly original and taken as a whole cover every important phase of coal mining practice.

Mr. Beard has done his work so thoroughly and so well that the books will be found of the utmost value as practical reference volumes on everyday mine operation as well as aids to passing examinations.

Mine Examination Questions and Answers

by

James T. Beard

Senior Associate Editor, *Coal Age*; Formerly Principal
School of Mines, International Correspondence Schools

3 volumes—\$7.50, payable in four monthly payments

FOR broadness of scope—for number of questions compiled and illustrations given—for all-round practical usefulness—this new work from the pen of James T. Beard exceeds anything of its kind yet published.

The author's great background of experience—eight years as secretary of the state mining board of examiners in Iowa; followed by sixteen years answering the state examination questions as associate editor of *Mines and Minerals*, and for more than a decade performing the same work for *Coal Age*—has enabled him to produce a work that is at once clear, practical and authoritative.

A complete survey of modern coal mining practice in question and answer form

Throughout it has been the aim to make the answers educational, that they may serve as a practical study of the subject and be of the utmost assistance to miners and students of mining who wish to fit themselves for examination. For this reason the answers will often contain more than would be required of a candidate in examination. In other words, the answers are such as to wholly acquaint the student with the subject in hand and enable him to give an intelligent answer to the question asked.

Free examination—no money down—easy payments

Look these books over for ten days at our expense. We take all the risk—pay all the charges.

If you find them to be what you want—if you are entirely satisfied with them in every way send us \$1.50 in ten days and then \$2.00 a month until the full price of \$7.50 has been paid.

Send the coupon NOW.

ROLLING MILL MACHINERY — PIPE MACHINES — ELECTRIC STEEL CASTINGS

Easton, Pennsylvania, U.S.A.

PROPER lubrication of your mine cars will save you power which is now wasted in overcoming preventable friction. It will save you labor which is now spent in replacing parts, worn out before their time by excessive friction. It will save you the cost of the replacements, and, in many cases, prevent decreased production while the cars are laid up for repairs. To obtain proper lubrication it is necessary to take many factors into consideration.

The bearings on mine cars may be divided into four general types, each of which has characteristics which dictate the grade of grease which lubricates it properly.

FIRST: The plain, oil-hole type having a hole drilled through the hub of the wheel leading to the axle bearing. No reservoir for the lubricant is provided; consequently a grease of the proper thickness (viscosity) to stick to the bearing must be used.

SECOND: The floating axle type in which the entire axle runs in an axle housing. Felt or wool packing is placed at various points on the axle to retain the lubricant which is carried in a reservoir in the center of the housing. The proper lubricant for this type of bearing is a grease which will feed easily by capillary attraction and not glaze or harden on the packing.

THIRD: The hollow wheel type which has a cavity surrounding the axle bearing to hold the grease. Small feed holes or slots are provided to feed the grease to the bearings. The size, shape and number of these outlets govern the grade of grease required for proper lubrication.

FOURTH: The roller bearing type in which tapered or straight rollers are used to carry the load. Lubrication is obtained either by packing the grease around the rollers or by providing a reservoir in the wheel or axle housing, from which the lubricant is fed as needed.

Superla Mine Car Greases

will lubricate your mine cars properly, regardless of the type of bearings with which they are equipped. These greases are insoluble in water

and are not affected by acid, water or gases usually found in mines. They possess unusual lasting qualities and do not harden or gum.

One of our lubricating engineers will be glad to make a survey of your mine cars and recommend one of the six grades of Superla Mine Car Grease to lubricate them properly. His visit will put you under no obligation, but it will show you the savings which proper lubrication will make possible.

Type CBA UNA Bond

A Simple Method For Good Bonding

Here is the way it is done.

No preliminary grinding of the rails is necessary.

A terminal of an all copper UNA Bond is placed in a small mold against the rail. An electric arc is drawn. Then UNA Metal (copper flux alloy) is melted into the mold with the bond strands. When the mold is full the bond head is solidly welded to the rail as shown by the above photograph.

It takes just about 35 seconds to weld each terminal.

The complete job is simple and readily learned. Besides, the operator has easy control of the welding and can judge each weld as it is being made.

When a UNA Bond is installed, maximum electrical conductivity is secured, for the bond is all copper from rail to rail. Thus full bonding value is realized.

"Specify UNA Bonds on your next order."

The Past, the Future and Hyatt Bearing Mine Cars

This season of the year puts us all into a retrospective frame of mind, we pause before our entry into the new year.

With the coming of 1924 the mine operator is greeted by greatly increased responsibilities and problems. The past is gone but its lessons and experience remain, and the wise operator is going to cash in to the greatest possible extent on them.

The important thing is to make the coming year a successful one by applying the knowledge that 1923 and the years gone by have left.

One of the lessons learned in the mining industry is that mine cars whose wheels turn easily on Hyatt roller bearings are the best cars obtainable. Time has proved that these easy moving cars are time, labor and power saving, that they cut lubricating costs, and that they last many years longer than ordinary cars.

The operator whose cars are now Hyatt equipped has solved his car problem for good and all. His mind is free to pass on to unsolved problems, and you know there are enough of those.

Put your mine car troubles into the past and save future regrets by specifying Hyatt roller bearing trucks for your old and new cars.

ROY EDWARDS

Steam Shovel Engineer

BLOCKER, OKLAHOMA

September 29th, 1923.

The Thew Shovel Company,
Lorain, Ohio.

Dear Sir:

Knowing that you are at all times glad to know of some good performance of the Thew shovels I am sending you three kodak views showing the Thew 3-A, 1½ yard steam shovel, shop #2148, equipped with a 32 ft. boom and 24 ft. dipper stick, digging slate, shale, clay and soil overburden that was 24 ft. deep when these views were taken. We have been in deep digging for some time but I am overcasting all material on one side and carrying a bottom that is 22 ft. wide. If anyone don't believe that I have dug material 24 ft. deep and 22 ft. wide just have them bring down their steel tape measure and I will show them. The Thew is a good reliable, rugged shovel to have on any job and this 3-A is the best stripping shovel built.

Yours very truly,

Roy Edwards

STATE OF OKLAHOMA,

March 26-1927

Thomas R. Jones Notary Public

Just a few of the 150 mines abroad using

The Rheo Washer

- 1—The Charbonnages de Bois-du-Luc (Belgium), one of the largest mines in Belgium, have just put to work recently a Rheo-Washer.
- 2—The Mines de Lens (France) had a Rheo-Washer before the war which was destroyed by "faits de guerre," have ordered another to replace it.
- 3—The Nixons Navigation Steam Coal Co., one of the most important mining concerns in Great Britain, have ordered a Rheo-Washer after comparative practical trials had been carried out on their coals.
- 4—The States-Mines of Holland have ordered a Rheo-Washer after practical trials had been carried out on their coal.
- 5—The Establishments Schneider & Co., the leading industrial concern in France, have ordered a Rheo-Washer for their mines in Decize.
- 6—The Administration of the French Mines in the Sarre Country have ordered six large Rheo-Washers, three of which are now in practical operation.
- 7—The Gewerkschaft Carolus Magnus, Palenberg, Germany, have ordered a large Rheo-Washer to replace a jig washery.
- 8—Hulleras de Riosa, one very big mining concern in Spain, have built at their expense an experimental Rheo-Washer, which has been put to work a few months ago, and have ordered a large Rheo-Washer.
- 9—The Usines Skoda, Prague (Tcheco-Slovakia), the biggest industrial concern in the country (20,000 men), have ordered a Rheo-Washer.

And now the Rheo-Washer is coming to help American coal operators obtain clean coal at lower cost.

For complete particulars on the advantages and operation of the Rheo-Washer clip and mail coupon.

A. France-Focquet
17 Quai St. Léonard
Liège
Belgium

The Rheo-Washer— What it is and does

- 1—A coal cleaning system that takes advantage of
 - (a) Specific gravity;
 - (b) Roughness of surface;
 - (c) Shape of the various pieces of coal.
- 2—The coal is washed down a long trough of variable grade with openings or traps at intervals in which the slate falls, being opposed in some cases by a rising stream of water, which prevents the coal being carried along with the slate.
- 3—A system of rewashing the middlings with the feed so that they aid in separating the clean coal from the slate, thus avoiding waste.
- 4—Simple construction—nothing to get out of order. Makes a separation of any desired degree with minimum waste.
- 5—Installation cost low. Labor costs reduced to a minimum. Its light weight, compactness and freedom from reciprocating parts removes the need for heavy, costly building construction.
- 6—Design permits of handling overloads and variations of feed.
- 7—Will wash all coal up to 4 inches—both anthracite and bituminous—with but one screening.
- 8—Not an experiment—a tried and proved system. Arrangements can be made to build it for your requirements entirely in the United States.

MR. AMAND ANDRY,

7th Floor, 375 Tenth Ave., New York, N. Y.

True Wire Rope Economy

The true cost of your Wire Rope is not the initial investment, but is dependent entirely on its performance.

Frequently high priced Ropes have been found to cost only half or two-thirds as much as cheaper Ropes, when measured in terms of *Service*.

HAZARD Wire Rope is the culmination of three-quarters of a century of Rope making.

Through constant study of actual working conditions by our engineers we know how to build exactly the right type of Rope for each operation.

Put your Rope problem up to us and let us show you what Wire Rope engineering can do for you.

"canned experience"

That old saying about experience being the best teacher is absolutely sound in one sense. But most of us recite it without thinking that experience may be of various sorts — *the experience of other men as well as our own*, "canned experience," if you please, ready for use. Just open and serve yourself! Why not take advantage of the experience of other men as far as we can and save not only years of time but many expensive lessons?

Do you know how much of the world's best research in the coal mining field is contained in

McGRAW-HILL BOOKS?

That single fact or table may be worth many times the price of the book to you.

Examine any of the books described below for ten days FREE
Just fill in and mail the coupon

1. McCrystle— MINE TRACKS

Their Location and Construction.

105 pages, pocket size, flexible, illustrated, \$2.00 net, postpaid.

A compact treatment of the design and installation of mine tracks. The book covers rails, ties, projection of haulage roads, grades, gravity, grades, frogs and switches, and the locating of the turnout.

2. COAL MINERS' POCKET BOOK

1200 pages, pocket size, flexible, illustrated, \$5.00 net, postpaid.

This great handbook contains more facts about coal mining than one man could possibly gain in a lifetime of actual practice. It is the one book everyone connected with the coal mining industry wants to own.

3. Shurick— COAL MINING COSTS

515 pages, 6x9, illustrated, \$5.00 net, postpaid.

This book helps you to answer the question: "What is the most economical way to mine coal?" It shows actual costs of doing work in representative mines throughout the country.

4. Reed— BITUMINOUS COAL MINE ACCOUNTING

221 pages, 6x9, illustrated, \$3.00 net, postpaid.

A sound practical treatment of this important question.

5. McGarraugh— MINE BOOKKEEPING

118 pages, 6x9, illustrated, \$2.00 net, postpaid.

A comprehensive system of records and accounts for mining operations of moderate dimensions.

6. McGrath— MINE ACCOUNTING AND COST PRINCIPLES

260 pages, 6x9, illustrated, \$4.00 net, postpaid.

A complete presentation of principles and methods.

7. Bacon and Hamor— AMERICAN FUELS

Two volumes, 1245 pages, 6x9, illustrated, \$12.00 net, postpaid.

Every coal company should have a set of this work. It covers the whole subject of the characteristics and economic utilization of fuels of all types.

8. Beard— MINE GASES AND VENTILATION

433 pages, pocket size, flexible, illustrated, \$4.00 net, postpaid.

All who are interested in making coal mining safer will find in Beard the necessary help and information on mine gases, safety lamps, mine ventilation, safety and first aid, explosive conditions, etc. No mine official or worker can afford to be without this book.

9. Prochaska— COAL WASHING

382 pages, 5½x8, flexible, 202 illustrations, \$4.00 net, postpaid.

The first systematic description of modern practice in the art of coal washing. This book will furnish the coal operator, through a study of chronological developments, with the necessary information to enable him to choose the apparatus and methods best adapted to his requirements.

10. Reed— BITUMINOUS COAL MINE ACCOUNTING

221 pages, 6x9, illustrated, \$3.00 net, postpaid.

An outgrowth of the universally recognized need for a uniform system of accounting and cost-keeping in the bituminous coal-mining industry.

Continuous Operation

with
Egyptian Shaker Screen Eccentrics

Dependable Service Under the Most Exacting Conditions

Egyptian Eccentrics are designed and manufactured for the mine operator who regards continuous and satisfactory operation as of first importance.

Egyptian ball face eccentrics are the result of extensive experience in the manufacture and use of tippie equipment, and are made to meet every demand of this severe service.

These eccentrics are self-oiling, requiring a minimum of attention, and with full protection against damage. The ball face eccentric adapts itself to minor inaccuracies in alignment of shaker shafts, where the ordinary eccentric would bind and break.

Send for circulars on Egyptian Equipment

It Pays to Replace

In development work, in taking out top and bottom, in raising and placing posts and caps in mine timbering and in loading coal in close quarters it pays to replace hand muckers with—

HOAR BABY SHOVELS

These compact, rugged, simple mechanical loaders will handle any material that a standard steam shovel will handle.

They will dig, spot, trim, clean up, load from 100 to 200 tons in a shift and han-

dle chunks up to a ton in size.

They are easy to operate, easy to maintain and have an extraordinarily long life

Send today for descriptive literature.

HOAR SHOVEL CO., Inc.

Dependable Performance from Scottdale Crushers

Continuous and reliable performance from Scottdale Coal Crushers is a certainty. Unusual quality of materials, heavy duty construction, and the ultimate refinement of simplicity contribute to this certainty of performance. Proven worth in actual service in hundreds of installations justifies our claims.

Whether your crushing requirements be for stoker, plant or yard purposes, there is a Scottdale Crusher especially made to meet your requirements. A crusher of wide ability and capacity, sturdy construction, simplicity and economy of operation—dependable. Capacities range from 20 to 240 tons per hour.

Long Service

—with a saving in first cost and upkeep

There are Hauser-Stander Wood Tanks which have been in service for 30 years, without one penny of repair expense! That is what Hauser-Stander means by long service.

This long service is due to the fact that Hauser-Stander tanks are rightly built. They are constructed by tank building craftsmen, who know woods and proper tank design. Fifty years experience is back of every Hauser-Stander tank job. Hauser-Stander Wood Tanks should be in use at your plant. Write for interesting free book on tanks and tank construction.

Caldwell

Tower Simplicity

The Caldwell Tubular Tower is the simplest, most easily erected and most graceful tower on the market. Its construction—of steel tubing, rugged socket castings and steel sway-brace rods with drop-forged turnbuckles—results in a tower of practically no wind resistance that will serve you long and faithfully. This tower is built for tanks from 1,000 to 40,000 gallon capacity. A prospective tower purchaser will do well to investigate the Caldwell Tubular.

“Tool Steel” Gear vs. Special Quenched

A large mining property equipped two test locomotives at the same time, one with “Tool Steel” pinions, one with a highly recommended “special” of another make, claimed to be “as good as Tool Steel.” The two locomotives operated in the same service for the same time and the pinions were examined and impressions taken to show wear.

SURE-GRIP

THOMAS

Thomas Hoists are built to meet every requirement of the mine operator and are designed and constructed with the sole idea of rendering efficient day-in-and-day-out service in shaft, slope or tippie hoisting, thus speeding mine production, and helping to keep the production costs low.

The illustration shows one type of Thomas coal hoist, being the type most commonly used for slope hoisting where the rope pull is in excess of 3500 pounds and where long lengths of cable are required. This hoist has patented band friction and deep flange drum. They are built in various sizes to meet different requirements.

SPOT QUICKLY AND ACCURATELY WITH SHAYS

LIMA

Shay Geared

LOCOMOTIVES

SPOTTING in minimum time is an important test of the suitability of a mining locomotive.

You can spot quicker and more accurately with a Shay than you can with a rod engine of the same power.

Unlike the rod engine, the Shay has three cylinders—two are always working when one is centered. Thus, the Shay starts quickly and with its full power.

Let us explain other Shay advantages which are of particular interest.

Plymouth Locomotive at Howard, Guthery & Co., Clarksburg, W. Va.

Plymouth Gasoline Locomotives in Coal Mine Haulage

In 1916, Mr. Dan Howard, President of Howard, Guthery & Co., Clarksburg, W. Va., bought a PLYMOUTH Gasoline Locomotive. This proved so satisfactory it was quickly followed by a repeat order. Mr. Howard writes:

"Our hauls are about 3000 feet and each Locomotive moves 12 loaded cars, or about 6½ tons each trip. The fuel consumption does not average over 7 gallons per day. The cost of upkeep is very low. I selected the PLYMOUTH after studying the performance of many different makes. The simplicity of its mechanism and accessibility especially appealed to me, and its performance has fully justified my judgment. I would not be content with any other make."

Air Line Transportation

When you haul coal aerially, *you're* the dictator of your tonnage—the weather-man isn't. Your aerial tramway buckets calmly deliver their guaranteed tonnage, while surface traffic is tied up tight by snow or flood, ice or mud.

B & B Two-Bucket Aerial Tramways have everything to recommend them economically: reasonable installation cost; low operating cost, both for wages and power (when used); extraordinarily low upkeep cost.

If your "per ton" cost of haulage seems unreasonably high, consult our Tramway Department. We will tell you frankly whether or not aerial transportation will solve your difficulty.

*Write for questionnaire on which
to tell us your haulage troubles.
Ask also for Catalog No. 9.*

OUR GUARANTEE PROTECTS

"Titan"

—the Original One-Piece
Titanium Steel Frog

That Weir Titan Frogs meet every need for stability and permanence in modern coal mine track construction has been amply demonstrated in service for several years. The Titan is the original one-piece titanium steel frog

and the standard by which all others must be judged.

In common with all Weir standard track equipment Titan Frogs and complete Titan Frog turnouts are always ready for shipment upon receipt of order.

WEIR FROG CO., Cincinnati, O.

Established 1882.
Largest and oldest
concern specializing in
mine track-work.

You cannot discount experience

When experience is built into mine track equipment its value cannot be discounted. Often the experience of individuals concerned with design and construction marks the difference between commonplace and distinguished results.

Experience is back of every Central frog, switch, crossing, switch stand or turnout you buy. Each unit embodies the crystallized experience of the members of this organization in serving the trackage needs of the coal industry for years.

The rougher the treatment—the clearer evidence of TIREX durability

Give TIREX rubber-armored Cable a chance to demonstrate its endurance on your cutting machines and loaders. Watch it as it is pulled over rough, sharp edges of rock and slate or left lying in muck or acid water. Not until you see TIREX Cable at work will you fully appreciate how much punishment it will stand. The extraordinary durability of TIREX Cable is due largely to the TIREX "rubber armor"—a tough, wear-resisting sheath which prevents in-

jury to the conductors from outside causes. It is today a well recognized fact that rubber-sheathed cords and cables—when properly made—will last many times as long as cables with other types of covering.

The peculiar construction of TIREX Cable insures flexibility and eliminates the danger of kinking. Install TIREX and keep upkeep down. Let us send you a sample—or particulars—and quotations.

We manufacture electrical wires and cables for all purposes, insulated with rubber, cambric or paper.

Monel Metal Screen in colliery of Legitt's Creek Coal Co., Scranton, Pa.

Legitt's Creek Colliery Tests Prove the Economy of Monel Metal Shaker Screens

By actual records of service under exactly parallel conditions of sizing at Legitt's Creek, manganese bronze screens were outlasted 60% by Monel Metal. Other mines report still greater superiority for this tough, corrosion resistant nickel alloy.

Strictly on the equipment cost basis, Monel Metal screens save money. And they save also in labor for replacement.

Why not cut your costs by installing Monel Metal screens?

A Recent Link-Belt Plant

RUN-OF-MINE coal, at the rate of 1000 tons per hour, is dumped, elevated to screen house, separated into five sizes and loaded into railroad cars, over

Link-Belt equipment at this completely Link-Belt designed-and-built plant.

It is another practical example of Link-Belt work. What can we do for you?

Shaking Screens.

View in picking house.
